The following utensils and materials will be required: nickel-plated or tin coffee-pot, with the handle attached to the side. This kind of a pot is better handled and the operation of reduction more easily watched than where a coffee-pot of the usual kind is employed. One 11 by 14 or 14 by 17 deep papier maché tray; one quart of boxwood sawdust or fine sawdust from white wood, i.e., willow, the boxwood dust being the best. It can be procured at any watchmaker's material supply house or from those who supply material for electro-platers and gilders. This kind of sawdust contains no resinous matter. Place the print to be operated upon, after being thoroughly wetted, in a sloping position upon a clean, smooth board covered with white oilcloth, or upon a clean sheet of glass, clipped at the two top corners with clean wood clips. Pour a pint of the sawdust into a half-gallon wide-mouthed bottle. Add thereto about three pints of clean cold water, shake it up well, then pour it into the coffee-pot. Now proceed to pour the water and sawdust upon the part to be reduced, and carefully watch the operation, because in a very short time the platinum will commence to wash off the paper. The continued pelting of the little crisp pieces of wood dust removes the excess of deposited platinum by abrasion, the result being that the heavy shadows soon begin to lighten up. In fact, if a very dark print be taken and carefully treated all over, the effect produced is like a beautiful engraving. When the operation is finished, it becomes difficult to believe that the resultant picture is a platinum photograph, except to those who know how it was produced. The use of sawdust and water was advocated some years ago for the development of a special kind of carbon print, but it fell into disuse, because it was a long and tedious operation. Such, however, is not the case when employed for the reduction of a platinum print that is too dense.

If a sepia platinum print be made and printed a little more deep than suited for the usual class of portrait, then treated as described, the effect is very charming, particularly if the print is a copy of an old oil painting. Head and bust portraits from life treated in this way possess a very desirable quality because of the genuine stipple effect aimed at by the use of a somewhat coarse-grained paper. Views and landscapes treated by this method produce effects that are not equalled by any other process except by beautiful engraving. The writer is not aware that this method of reducing the over-density of a platinum print has ever been brought into use. It will prove to be both a new and novel power in the hands of the skilled photographer. It could no doubt be applied to other photographic prints, but the object here is to point out its use in a direction where it has already proved its value, where it might be the means of creating a new and separate class of portrait, enabling the photographer to produce a special portrait of a remunerative character, and forming a special feature of attraction to his studio.

The production of platinum images upon porcelain or opal glass is not an impossibility. They have already been made, both in blue-black and brown-black, and may before long become a commercial article. The results, with such pure whites as that of a porcelain or opal base for the high lights, leave nothing to be desired in the way of black and white when applied to portraiture. Platinum opals will become an accomplished fact as well as carbon opals. With a glass or porcelain base the reduction of a platinum image can be easily accomplished by chemical means, and can be strengthened by alternate toning with gold and platinum.

The sawdust reducing mixture can be saved for future use. The best plan to adopt is to wash the sawdust well, then wring it as dry as possible in cheese-cloth, and lay it out upon blotting paper to become quite dry. Another point may be mentioned here. In an overdense platinum print, especially one made during the hot weather, the whites are very apt to become

September 9, 1904.]

lightly grayed. This grayness is easily removed by the saw-dust and water reducer, so that the process becomes doubly valuable. With the smaller sized platinum prints that are produced upon smooth paper, and where it is so often desired to have them a semi-gloss, so as to make the shadows more transparent, this may also be readily accomplished with a surface that is quite waterproof, one that not even mild acids or alkalis will affect. To accomplish this the prints must be well washed and dried in blotters, so as to lie quite flat. This is best done by first draining the water well from the prints, then blotting them off between clean white blotters. After this is done place the prints in another set of clean dry blotters upon a very level board or sheet of thick plate glass. Place several blotters at the bottom, if glass be used; thus with two blotters between each set of prints place a level piece of board upon the top and submit them to considerable pressure for the night. The next day the prints may be removed, that is, if they are quite dry. Procure a glass slipping bath, such as is used for the wet collodion process. Fill it nearly to the top with the following:—Albaline, 1 part; thinner, 1 part. Take the prints one by one, dip them completely in the mixture, hold the print up to drain by one corner, then clip it at each corner with two wood clips, and suspend it to dry away from dust. (The prints should not be rimmed until after this operation.) When dry, trim prints to size and prepare to mount with a good strong paste, by rubbing it well across the back of the print. Perform this operation thoroughly, then mount as desired, taking care to hold the blotter that covers the surface of the picture with the left hand, while applying the roller with the right, so as to prevent the picture from slipping. Roll down well, wipe off any excess of paste with a damp sponge, cover with clean blotter, then place under pressure until dry. When dry, remove the prints, flatten them out by passing them through a rolling press, when it will be observed that the shadows are very transparent, the whole picture presenting the surface of an artistoplatino with intense blacks. It will be found that prints tested in this manner are about as waterproof as it is possible to make a paper print, and that on the whole it approaches the effect that is observed when a platinum print is wet. This will no doubt meet the requirements of many photographers who have desired such a result.

The precise effect of a platinum print as seen in water can be produced in a dry state, a method for accomplishing it will be described in a future article in this magazine.*

THE ILLUMINATION OF THE DARK ROOM.*

SEVERAL articles have been published by me with regard to the subject of lightening up dark rooms. Daily more experience is acquired respecting the suitable arrangement of light for the dark room, especially as regards the use of colour-sensitive plates and concerning the phenomena appearing when ordinary plates are handled.

There is no light extant which does not affect plates as sensitive as bromide plates are, and which if acting on them for any length of time would not cause fogging when they are developed. Even the most perfect devices for producing non-actinic light are only in a figurative sense absolutely reliable, and one can easily ascertain that an ordinary plate if exposed for a sufficiently long period of time is sensitive to any kind of light visible to the eye. If artificial perfectly pure red light is obtained by creating through a prism a spectrum of sufficient length and then separating this light by a crossed prism from the other light as is always admixed owing to reflex

phenomena one readily perceives that, given sufficient intensity and a sufficiently long exposure, even extreme red light will affect a photographic plate. If this holds good for spectrally thoroughly purified light of long wave lines it holds all the more good for any red light separated by means of ordinary coloured glass. Even the most perfect filters—let alone the far less perfect ruby glass usually used—transmit light which, if of sufficient intensity, affects a photographic plate in a short time. An experiment in this direction can easily be made. If one produces deep red liquid strata which previously have carefully been examined spectrographically and which are free from ultra violet light that not infrequently passes through certain red filters, and exposes under such a filter a plate to sunlight, the plate will, even in the event of there being transmitted no light of a shorter wave length than 650, show in a few seconds a developable impression. Hence all attempts at developing plates by the aid of ever so perfect filters in broad daylight or sunlight are brought to failure.

To provide practically light-proof illuminations of dark rooms, care has to be taken therefore, not only that so-called ineffective light passes through the filters, but also that the intensity of the light-employed does not exceed a certain degree. It is therefore impossible—at least as far as gelatine plates are concerned—to provide for the dark room light-proof illumination which would be brilliant at the same time; and this is all the less feasible, the less perfectly the filter mark the boundary line.

The worst in this respect is, as is well known, coloured glass. When examining in direct sunlight, the spectrum of even the best ruby glass, it appears that the red light transmitted is weakened, whilst with the red light considerable quantities of green and traces of blue light will pass. This remark applies to all kinds of ruby glass in general. It is true the shade can be taken so deep that it becomes difficult to demonstrate refrangible light at all. But even in such a case the fact in question may be demonstrated by taking a spectrographic picture with a wide slit and intense rays of concentrated sunlight.

Other conditions being equal, the demand made on a filter will have to be all the greater the richer the light employed is in refrangible rays. Even an imperfect filter of ruby glass is tolerably useful for petroleum, or ordinary gas-light, but much less so for electric incandescent gas-light, daylight or electric arc-light. The use of incandescent gas-light as source of light for the dark room is but little advisable, because of its being comparatively poor in red while rich in green rays, which latter display an intense action on the plate, and are more or less perceptibly transmitted by ordinary ruby glass.

Hence follows that the power of dark room filters must depend upon the source of light employed—viz., on the one hand on the intensity and brightness of the light employed, and on the other hand on its nature and composition. It is much easier to provide a tolerable dark room filter suitable for petroleum and gas-light than for a daylight window.

Seeing that the intensity of the red light may not be increased ad libitum without running the risk of fogging the plates a light filter must always be arranged so as to allow only a certain amount of light to act on the plate, and it will answer its purpose all the better the more the transmitted light is purified of any refrangible rays. The greater the degree of such purification the greater the amount and brightness of the light that may safely be employed. When using ruby glass panes, the illumination of the dark room, if chosen sufficiently dense, will always be exceedingly imperfect in the event of ordinary gas or petroleum or gas lamps being used. Ruby glass absorbs far too large a proportion of useful light, whilst transmitting at the same time detrimental light unless with a very deep ruby stratum. Far better results are obtained if in the place of ruby glass suitable coloured filters are em-

* From a pamphlet, "More Light for the Dark Room," published by A. Staley & Co., 19, Thavies Inn, E.C.

ployed, as the absorbing power of artificial dyes is far better and more pronounced than that of ruby glass. When daylight or artificial sources of bright light are used, one is hampered in two directions. In the first place the filter must be so dark that absolutely none of the large proportion of refrangible light is transmitted, and, secondly, the red light must be subdued to such an extent that it is prevented from exerting any detrimental influence. Both drawbacks are more successfully avoided by means of other colour strata than those feasible in ruby glass.

When daylight or electric arc-light is used the filter strata must, it is true, be prepared accordingly if they are to transmit non-detrimental light under such circumstances.

From the foregoing it will be seen that the task of properly illuminating the dark room according to existing circumstances is not an easy one and that the production of suitable artificial filters for this purpose requires close study and an extensive practical experience. Photographers will not always be able to prepare serviceable filters from artificial dyes having the required characteristics. A long-felt want will be met therefore by enabling them to buy such filters of good quality.

There are now produced good filters for illuminating the dark room, and there are now placed on the market gelatine dark room filters answering all reasonable requirements—viz., filters which are coloured so as to give with the various sources of light a useful and yet the brightest possible illumination.

For the illumination of positive rooms, for silvering albumen paper, for charging copying frames with copying papers, for developing Lenta papers, and other little sensitive preparations, gelatine filters of a suitable yellow tint will prove sufficient.

For developing ordinary dry plates with the brightest possible light there are filters transmitting intense and yet perfectly safe red light, whereas for daylight illumination and the handling of highly coloured sensitive plates, as well as for panchromatic plates and collodion emulsions deep red, exceedingly reliable and yet bright filters are made. When there is an opportunity I shall revert to the subject of the use and characteristics of these filters on the basis of practical experience.

DR. A. MIETHE.

TONING BROMIDE PRINTS.

I HAVE been using sulphate of copper for some time past in toning Ilford bromide prints, and have found it excellent. Many other methods of obtaining the same result have been suggested—iodine, potassium bichromate, potassium ferricyanide, etc. I have tried them all, and find that the copper sulphate is the best. It takes a little longer than iodine, writes Mr. Harold Baker in "Photographic Scraps," but is far less expensive, and in my hands has proved more reliable. Some have questioned the permanence of the results, but it seems to me that such prints are likely to be quite as permanent as ordinary bromide prints, as, if the operations are properly carried out, the chemicals which are used to bleach the print before toning, fail to have any effect on the finished toned print. Toned bromides by the old cooking process, with hypo and alum, have proved very permanent, and as the chemical change produced by the sulphide process is precisely the same as by the cooking process, but far more complete, the results ought to be more permanent than those by the cooking process. The sulphide process has several great advantages over the cooking method. First of all, no special kind of print is necessary, as there is no change in depth. A good black ordinary print will tone to a good colour.

With the cooking method the print must be darker, as the process reduces the depth, and, in order to get a good sepia, it is necessary to over-expose and use a restrained developer

to obtain a greenish print; at times, also, patches of prints would refuse to tone at all and remain black, in spite of even of prolonged boiling. I found these patches were caused by hypo and developer being on the print at the same time either hypo from the fingers during development, or developer remaining on the print during fixation. None of these troubles need be feared with the sulphide process.

The solutions needed are simple. First, the prints should be hardened with alum or formalin (I prefer the former). After slight washing they are bleached thoroughly in

Copper sulphate	1 oz.
Potassium bromide	1 oz.
Water	10 oz.

This can be used again and again, until it works too slow. Next, the whole of the copper remaining in the paper must be washed out; to assist in this the prints should be placed in a 2 per cent. solution of nitric acid for five minutes, followed by more washing. Finally they are toned in a very dilute solution of sulphide of sodium.

The copper solution converts the silver of the image into silver bromide of a pale yellow colour, and the sulphide converts the bromide into a rich brown sulphide of silver, a very stable salt.

It is most important that the whole of the copper should be removed from the paper before the sulphide is applied; if it is not, the paper will be stained brown, a stain which cannot be removed.

The sulphide solution should not be used a second time and should be used dilute, as it has a markedly softening effect on the gelatine, and if too strong will blister the print very badly. It is important, however, that it should be allowed to act long enough to convert the whole of the silver bromide into sulphide. The sulphide of soda has a very unpleasant smell, very much like rotten eggs, so that it should be used in a well-ventilated room. The solution needs some care in its preparation. The sulphide should be obtained from a reliable chemist, and should be as pure as possible. The crystals should be bought in bottles as they are extremely deliquescent, and will almost dissolve in their own water on crystallisation. I usually make an almost saturated solution which is boiled in a flask or an enamelled iron vessel; when cool the solution is filtered through filter-paper to remove a fine black precipitate which is thrown down. One ounce of the saturated solution should be diluted to 50 oz. for use, but it is convenient to keep it in the concentrated form and dilute when required. The strong solution should be handled with care, as it has a very solvent action on the skin.

If only a few prints are to be toned, the iodine process may be used, but for large batches iodine is expensive. The ordinary tincture of iodine from the family chemist answers quite well, diluted, of course. The first change is to darken the paper support of the print to a deep purple, the image then begins to change to a pale yellow (silver iodide), and the bleaching is continued until the print appears as a negative, a yellow image on a deep purple ground; it is then passed through a dilute solution of sodium sulphite, which discharges the purple colour of the paper so that it is possible to see whether the whole of the black silver bromide has been converted into yellow iodide. If any black remains, the print should be washed and returned to the iodine solution; when thoroughly bleached it should be washed and placed in the sulphide solution.

The exposure and development have an influence on the colour of the toned print, long exposure and restrained development produce a more yellow colour. Altogether the process is a great advance on the hypo and alum cooking method, with less risk of failure and better results.

J. CRAIG ANNAN.

frequently said, and often also with much truth, that a prophet has no honour in his own country. The great men of the day, however, oftentimes defy this prophecy, and then admiring neighbours find it the lie direct. Photography is so much a thing of to-day, that it is rare to find a photographer proving the falsity of this doctrine; Mr. J. Craig Annan, however, who is essentially a leader, defies this doctrine, and "The Bailie," the Glasgow "Punch," last week publishes an appreciative notice of him, under the well-known heading of "Men you Know." The fact that he figures as 1,663 proves that this feature is of sufficient antiquity to merit mention, we therefore make no excuse for quoting "The Bailie's" graphical appreciation in extenso:—

photography also among the fine arts? is a question around which an intermittent warfare has for some years been waged with sharp-shooting and raising of dust and smoke. To the unalloyed genius known as "the man in the street" there seems no peculiar reason why the camera should not be considered as legitimate an instrument for the expression of the artistic spirit as the oil or the paint brush; but this the brethren of the palette are not to admit. Art, they say, is nature seen through a temperament not through a glass lens; its purpose is not to report a fact, but convey an impression; and its method includes a certain selection and arrangement of outlines and masses, a suppression of detail, a barrenness of composition, and a generalisation of effects, which, contended, cannot be attained by the use of mechanism.

is usual in such controversies, the only effective answer is supplied, not by the man of words, but by the man of action, not by who says the thing can be done, but by him who does it. Among such, the "Bailie's" "Men you Know" for this week occupies a prominent place, and this fact has received an emphatic recognition in his selection by His Majesty's Commission to the St. Louis Exhibition to represent Great Britain, along with General Bouverie, on the International Jury for the photographic section of that gigantic show.

his is the culminating honour in a series of similar tributes that have been paid to Mr. James Craig Annan in his capacity as a visitor of the uses of the camera. These date as far back as 1893, when his exhibits at the first exhibition of the Photographic Salon in London, by their combined character of restraint and unconditionality were considered the most striking features in an exhibition destined to become the basis of "the new photography." Owing to this, Mr. Annan appeared as an exhibitor at Brussels, Vienna, New York, and Munich, in all of which cities his work has been most favourably received by the critics; while the sums of Dresden and Hamburg have procured specimens of his productions for a place in their permanent collections. In January, 1900, the Royal Photographic Society instituted a series of "one man shows" in their rooms in Russell Square, and invited Mr. Annan to inaugurate the series by contributing a representative selection of his most typical work. Again at our own International Exhibition of 1901, Mr. Annan was the convener of the photographic committee of the art section; and the beautiful and complete collection of photographs gathered there from all parts of the world very largely due to his energy and influence.

the principal incidents in Mr. Annan's life may be told in a few words. Born in Hamilton, he is the second son of the late Mr. James Annan, who was well known to a previous generation as one of the leaders in photography, especially in its artistic developments. These who can remember the late Mr. Annan do not require to be reminded of his keenly artistic sensibilities and his strong interest in his craft. Mr. Craig Annan may be said, therefore, to have inherited a photographic and artistic atmosphere from his childhood, in a metaphorical sense to have been cradled among *materia photographica*.

After learning the rudiments of his craft in his father's works, our subject spent some years studying chemistry in the laboratory of the Professor Dittmar, and shortly afterwards, in 1883, went to Vienna to learn the then new process of photogravure under the tutor, Herr Karl Klic. Having mastered the mysteries of this

beautiful method of reproduction, Mr. Annan returned to this country, where he has since worked the process with success and increasing reputation. The first to introduce this method into Britain, his firm of T. and R. Annan and Sons still hold a leading position among many later competitors, as is evinced by their illustrations to such *de luxe* books as "The Portraits of J. S. Sargent, R.A.," "The Works of Sir Henry Raeburn," and "The Bridgewater Collection."

The Man You Know is of a modest, unassuming habit of mind, and is greatly beloved by all who know him. He is now on his way across the Atlantic. "The Bailie" congratulates the St. Louis Exhibition authorities on their visitor, and wishes him a calm sea and a prosperous voyage.

The article is accompanied by a full-page portrait of Mr. Craig Annan.

THE PHOTOGRAPHIC SURVEY OF ESSEX.

THE question of local and county photographic surveys has frequently been debated in these columns, although the exact purpose of the ultimate results of the work remains in many instances a matter for speculation. These surveys undoubtedly provide information that may be invaluable to future historians and other workers, but it is eminently necessary that such surveys should be systematic and thorough.

Mr. A. P. Wire, in replying to an editorial note in the "Leytonstone Express," complaining of the lack of interest taken in the photographic record of Essex, which Mr. Briscoe, of the Stratford Technical Institute, tried to inaugurate over a year ago, says:—"As far as an organised survey of the whole county is concerned, this, as far as I know, has not been attempted. It is too gigantic a task for any individual to accomplish, and to do it would require an organisation in touch with every part of the county. Such organisation does not exist, and who is the person or where is the society that can call such an organisation into existence? It seems that Mr. Briscoe did nothing more than read a paper about it at the meeting of the Essex Field Club. It is certain that the Executive of the Essex Field Club has not the organising ability in any way adequate to carry on a work of this kind. Notwithstanding this, a great deal of work has been done, and is being done, in our county. In the pages of the "Journal of the Essex Archaeological Society" and of "The Essex Review" may be found many Essex records, and numbers of amateurs are at work making and collecting pictures. The National Photographic Survey, under Sir Benjamin Stone, of course, covers Essex, and this survey would receive a great deal more help were it not for the rule that only platinotype prints are accepted.

"Colchester has been done, I may say, exhaustively. In the Town Hall and Museum of that town are large collections of pictures and antiquities that illustrate the history of the town, and one amateur residing there has a vast collection of pictures and notes that we all hope will ultimately become the property of the Corporation. As for this district, there is at work an organisation for the 'Survey of Greater London.' Almost all the work of this committee is done by the voluntary active members, who photograph, draw, make plans, etc., as the committee determines. This committee not only collects information, but from time to time, as funds allow, publishes monographs, or memoirs. Among these the committee has lately published a 'Monograph of the Great House, Leyton,' with numerous illustrations. I have worked on this committee for some years, and we have in hand now monographs of West Ham Parish Church, East Ham Old Church, and Waltham Abbey, all in Essex, besides others in various parts of London. This committee not only does this record work, but uses its influence to prevent the wanton destruction of old buildings. It assisted in this way in saving the Trinity Almshouses, Mile End, and the Church of St. Mary, Stratford-le-Bow. After Mr. Briscoe read his paper I wrote and suggested that he should organise a survey of West Ham, for there is plenty to be done in that large parish, but no reply came. It seems that if this work is to be successfully carried out, it must be done under the auspices of the local councils, for, alas! very, very few people take an interest in antiquarian matters, and nothing of this kind can be done without money."

PATENTS AND RECIPROCITY.

At a time when everyone is considering schemes for the encouragement and maintenance of our trade, it is, perhaps, not out of place to touch upon certain points connected with the method of promoting industrial activity in this realm by grants of letters patent, a subject included amongst those now receiving attention at the hands of the Tariff Commission.

England (writes Sir Lloyd Wise, in the "Times,") was the first country to recognise that inventors who introduced or improved an industry benefited the community, by causing an increase in the trade and employment of the people, and to adopt the method of rewarding inventors by the grant of letters patent securing to them the exclusive right to use their inventions for a limited period. Her remarkable rise to the position of the leading industrial nation of the world has been due more largely than is generally allowed to the adoption of this means of encouraging inventors, the success achieved being commonly attributed rather to natural resources and the commercial instincts of the people; and it is a standing memorial to the astuteness of the legislators of the time of James I. that, notwithstanding the violent prejudice against monopolies which had been caused by the gross abuse by the Crown of its prerogative, in granting monopolies of various trades to courtiers, and for the purpose of raising money, they expressly excluded letters patent for new and useful inventions from the operation of the statute which declared monopolies in general illegal. Nearly every civilised nation has followed our example by granting protection for inventions.

But whilst an exclusive privilege of limited duration is calculated to enable an inventor to reap a reward fairly proportionate to the benefit accruing to the public from his invention, such privileges have occasionally been so exercised as to have a detrimental effect, owing to greed of owners and attempts to monopolise the home market for imported articles by preventing manufacture in this country. The more important the invention the more disastrous to our trade is such a course likely to prove. In an extreme case it is conceivable that the effect might be to cause an industry to dwindle during the term of the patent until, on its expiration, the foreigner found himself in practically complete possession of the market. Obviously, to admit of such a possibility would be to carry the principle of reward altogether beyond reasonable bounds.

Recourse has in many countries been had to expedients for protecting manufacturers and consumers. Thus a patent is prevented from being utilised to secure a monopoly for imported goods, either by direct prohibition, as in France (subject, however, to international arrangements) and Canada, or by being made liable to revocation on failure to carry on the manufacture within the country after a given lapse of time, as in Austria, Belgium, Denmark, France, Germany, and elsewhere. But our law does not go so far. Under it importation of patented products without manufacture here may go on indefinitely unless some interested party, possessed of ample means and sufficient courage to run the risk, should succeed in satisfying probably the most expensive tribunal in the land—the Judicial Committee of the Privy Council—that the reasonable requirements of the public with respect to the patented invention have not been satisfied.

Under the Patents Act of 1883 the Board of Trade had power, in certain cases, to order a patentee to grant a licence on the application of an interested party. The practice was to delegate to a referee the duty of hearing and reporting on the matter, and then to decide what, if any, licence should be granted. The machinery was found to be needlessly complicated, and in the case of a foreign patentee residing out of the jurisdiction either inoperative or very difficult to enforce. In 1900 the Board appointed a strong departmental committee (of which Sir Edward Fry was chairman) to inquire and report as to this amongst other patent questions, and the Patents Acts of 1902 resulted, although its provisions are not entirely in accord with the recommendations of the committee.

Under that Act any person interested may petition the Board of Trade for a compulsory licence, or in the alternate revocation of the patent, on the ground that the patentee has not satisfied the reasonable requirements of the public. Assuming a *prima facie* case to be made out, the petition is (unless the parties come to terms) referred to the Judicial Committee of the Privy Council. If the patent is worked or the patented article is manufactured exclusively or mainly outside

the United Kingdom, and the patentee fails to disprove the grounds of the petition, the petitioner is entitled to succeed. The reasonable requirements of the public are not to be deemed to have been satisfied through default of the patentee to work his patent or to manufacture the patented article in the United Kingdom to an adequate extent, or to grant licences on reasonable terms, any existing industry or establishment of any new industry is unfairly prejudiced, or the requirements for the patented article is not reasonably met. If the committee of opinion that the reasonable requirements of the public will be satisfied by the granting of licences the patent may be revoked but a patent cannot be revoked until after three years from its grant or if the patentee gives satisfactory reasons for his default.

The Associated Chambers of Commerce recently passed a resolution to the effect that the law should be so altered as to secure the enforcement of every patent if the invention, though workable in this country, is not worked within a reasonable time. This is a needlessly sweeping proposal, as a patentee who is not mainly interested in manufacturing abroad, if unable to supply the home demand himself, is usually quite willing to grant licences on reasonable terms; and it would be both unjust and impolitic to deprive him of his rights simply because of his inability to manufacture or to induce others to do so. Under such a provision small encouragement would be afforded to inventors of limited means, because it would operate as an incentive to manufacturers to abstain from taking licences, so as to bring about the extinction of the patentee's rights. Indeed, the arguments adduced in support of the resolution were directed against foreign owners of British patents manufacturing abroad and importing into this country to the serious detriment of our manufacturing industries. They might advantageously extend to prevent this; also to impose on foreign holders of British patents conditions analogous to those imposed by the patent laws of their own countries.

It is intolerable that foreign manufacturers should be helped by our patent laws to flood this country with foreign-made wares, while their patent laws operate to exclude English-made goods from their markets. Our manufacturing industries are sufficiently handicapped by prohibitive tariffs, but even retaliation in that direction would suffice to protect them so long as articles unconditionally protected by letters patent here could be imported. Neither would the consumer be protected; because, competition being shut out, those who purchased the articles could be made to pay such a price as would include any import duty that might be imposed.

It is desirable, then, that our Government should be in a position to secure reciprocal treatment for British owners of foreign patents, and to this end our law might with advantage be so amended as to provide, not only for compelling patentees to grant licences, but under certain circumstances, and subject to international arrangements, for requiring patented manufacturers to be carried on in the United Kingdom, and for prohibiting importation of products protected by British letters patent, all of which might be subject to rules to be made from time to time by the Privy Council or the Board of Trade.

Any such enactment should give ample power of discrimination as not to inflict hardship upon and discourage English inventors; would, for example, such a measure as suggested by the Associated Chambers of Commerce; and, furthermore, should provide a more ready and economical method of dealing with applications for compulsory licences than the present one, which seems eminently calculated to encourage oppression of persons of moderate or small means by those who command capital.

Seeing that, even in cases bristling with legal and technical difficulties, the Comptroller-General of Patents, or the Chief Examiner or his deputy, has to determine (subject to appeal to one of the law officers whose decision is final) in every opposed case, whether letters patent shall or shall not be granted at all, there appears to be no reason for driving applicants for compulsory licences to so exceptionally expensive a tribunal as the Judicial Committee.

The law relating to compulsory licences would be far less likely to remain practically a dead letter if, with a view to enabling decisions to be obtained quickly and cheaply, it were amended on the lines of the scheme embodied, on my recommendation, in the Canadian Patent Act of 1903, according to which the head of the Patent Office or his deputy (aided, where he or either party so desires, by a specially qualified assessor) is the authority for dealing with applications

onsory licences, and if the owner of a patent refuses or neglects simply within a stated time with an order for a licence, the patent becomes null and void.

The aim of any amendment in our law should be, whilst giving the patentee a right free from needless uncertainty, so that he may be enabled to derive due advantage from his invention, at the same time afford manufacturers and traders an opportunity of readily protecting themselves against any arbitrary owner of letters patent who may seek to exercise the privileges thereby conferred in such a manner as to do injury rather than to confer benefit upon the community.

TRADES AND FACES.

It is an undisputed fact that a man's trade or profession affects, more or less noticeable extent, not only his disposition, but his physiognomy. That certain faces appertain to certain calls is a matter of everyday observation. The expression of the "key" man—be he trainer, jockey, or groom—is quite unmistakable and peculiar. The professional cast of features of the doctor or lawyer is equally well known, and yet more strikingly distinctive is the face of the actor. Butchers and shoemakers, writes Miss Bruce Bacon in the "English Mechanic," tailors, publicans, and servants all have facial peculiarities which they hold in common with all other members of their trade, and to a keen observer of human expression all workers of whatever station bear upon their features the impress of their labour. To state the fact is easy enough, to explain it is another matter. The connection between thought and its physical expression, as also between emotion and its physical, especially facial, concomitants, is ever complex and elusive. Nevertheless it is those who have devoted careful study to the matter, and whose results have proved sufficiently curious and interesting. One especially instructive instance, among many others, has been related by a well-known medical man. In his work as surgeon in the hospital shipbuilding town, he was struck with the lowering brows and gruff expressions of the riveters and boiler-smiths with whom he came in contact. Only by experience did he come to understand the apparent watchful hostility which each seemed to exhibit was in reality a trick of the countenance merely, and not at all indicative of the actual feelings. And pondering over this he arrived finally at the conclusion that the scowling look, which he maintains is common to all kinds of smiths, is due to the constant automatic contraction of the brow to protect the eyes from the flying sparks, as heavy sleage descends on the glowing metal. A blacksmith is, by rule, credited with being a serious and downright man, who looks the whole world in the face and stand no nonsense. It has been noted that the mere act of striking heavy blows, accompanied always with a flush and a frown, has about it so much suggestion of wrath and determination as in time to affect the character to a certain extent. In the case of the shipbuilders also their work is noisy as to render them all slightly deaf, which infirmity always has a closely watchful expression to the features. Another curious, some may think far-fetched, explanation of a "trade expression" has been given in the case of the tailor. Let anyone watch the face of a person engaged in cutting a thick piece of material with a pair of scissors, and it will be seen that the lower part of the face works in involuntary unison with the blades. May not (so it is argued) the constant working of a tailor's jaws concomitantly with his shears help to bring about that cast of countenance which distinguishes him.

The well-known and recognised type of face belonging to the key man has its peculiarity chiefly in the set of mouth and jaw. This is explained from the fact that the muscles which close the jaws and compress the lips are always called into play when a man is asserting his will over that of a horse. The incessant manipulation of his own power and will over that of an animal tends to that firmness of jaw and thinness of lip which a horseman wears. Somewhat different when the command is exercised over men and of animals. The firm mouth is still seen in the drill sergeant; the commanding eye—which is absent in the groom—is also added, as in dealing with men the higher method of expressing authority is made use of. Generally speaking, it is strenuous contest with ever-rising minor difficulties which produces thin and compressed lips.

Many housewives who suffer the little worries of life to prey upon them, or whose existencies are a perpetual struggle to make both ends meet, exhibit this peculiarity, even to extremes. Compressed lips are generally rather a sign of weakness than strength. A strong will is above the perpetual petty strife they indicate. The commanding officer, sure of his men's obedience, lacks the look of tension which his sergeants wear, and that absolute monarch, the sea captain, though his face carries authority and power, has the easily-set mouth of confident assurance. It has been remarked that there is a certain marked resemblance between the types of face, especially the calm lips, belonging to the naval officer and the engine driver, brought about by the fact that both are absolute masters of the powers they control. The priestly face bears also the sign of authority, though the thin lips are frequently present, added to a sense of the dignity of position. For some mysterious reason also the skin, especially beneath the eyes and about the throat, tends to be full and baggy—a peculiarity the cleric shares, though in a lesser degree, with the musician. The doctor's face, as also the lawyer's, wears an expression of weighty perspicacity, whether deserved or not, though it may be noted that the leading members of both professions do not display their distinctive symbols to anything like the same extent as do the rank and file, probably because the constant desire to impress and the effort to appear learned is no longer necessary. It is curious, by the way, though undoubtedly, how emotions, the effect of which may at the time produce no perceptible change in the face will, if constantly indulged in, nevertheless affect the whole cast of countenance, showing that all feelings, however slight, send impulses to the appropriate muscles, which, though too faint to make outward movement, yet are cumulative in their action. In the same way constant, though unconscious, mimicry has its outward result in time on the expression. It is frequently remarked how people who have long lived together—as elderly married couples—have a tendency to grow alike, due, doubtless, to that facial limitation we are all so prone to. It needs no insisting on how liable we are to unconscious imitation; the way in which a yawn will spread among a company, if started by one individual, being a well-known case.

The faces of actors are peculiarly distinctive and unmistakable. An actor's art involves the stimulation of the muscular factors of expression. Not only must he emphasise his facial movements, so as to make them plainly apparent to his audience, but by his constant change of rôle he is called upon to portray all kinds of emotion in turn; consequently his expression muscles are exercised as thoroughly as an athlete exercises his biceps, and when seen at rest no one group of muscles out-pull another in an actor's face, giving a peculiar, slightly mask-like or wooden aspect to the whole. An even layer of subcutaneous fat seems also to be induced by constant emotional stimulation of the features. One noteworthy result of this continual facial exercise is to overrule and obliterate the usual records which time brings to every face, and consequently to preserve in a remarkable way the youthful appearance for which actors and actresses are so well known. Actresses, in particular, seem possessed of a special power of indefinitely preserving their youth and freshness, even though the life they lead is an unnatural and more or less unhealthy one. Coming to musicians, professional and otherwise, it has been noted that they are mostly distinguished by a bagginess beneath the eye and jaw; the eyes are prominent and dreamy, and the mouth characterised by a lax and flabby set of the lips. The mouth, indeed, approaches in appearance near to the recognised mouth of the sensualist. It is a curious fact that this mouth, which ever accompanies the artistic temperament, whether in music or other arts, always has about it the suggestion of habits of self-indulgence. It may probably be explained in this way—that the true artist is born, not made, and he therefore achieves greatness more by following his own spontaneous emotions than by painful efforts. Thus his work is, in a sense, a species of self-indulgence; and it too often happens that this principle of drifting, fostered by the artistic temperament, widens and embraces other departments in life.

QUITE a novel bid for popularity is now nightly drawing all Leeds to the Coliseum Music Hall. During the evening some thirty photographs of people snapshotted in the street are exhibited on a screen, and if any of the persons happen to be in the house and recognise themselves they receive a sovereign each. Fresh photographs are shown every night.

"MYSTERIOUS MARKINGS" NOT CAUSED BY SPIRITS.

THE newspapers have contained a good deal lately on the subject of "spirit photography," and besides actual portraits, which are put forward as spirit photographs (says the "Barnet Photographic Record") a number of plates have been exhibited which displayed what were termed "mysterious markings." Whatever may have been the origin of the particular markings in those instances, it is only too easy to make plates which shall give mysterious markings every time.

The idea that glass is perfectly inert and insoluble is one which it is very hard to banish. We are so accustomed to fill a glass with water or other liquid, empty it, wash it out, and dry it, and regard the glass as unaffected by the process, that it comes as a positive shock to learn that it is impossible to dip a glass in water without some—the merest trace, it is true, but still a trace—of it being dissolved, and that when once a chemical solution has come in contact with a glass it is a difficult, almost an impossible task, to clean that glass so perfectly that a delicate test will not afterwards still show traces of the chemical to be present.

When wet plates were principally used, and photographers had to prepare them themselves, they were in the habit of cleaning off the spoilt negatives and recoating the glass. It was then by no means an uncommon occurrence for the original image to develop together with the second image, even after the glass had received what seemed to be a most thorough cleansing. The conditions under which the wet plate worker carried out his photography did not make this of so much importance as it would be now. He coated, exposed, and developed his plate before leaving his subject, and an occasional failure only meant an immediate repetition of the operations.

Now that the dry-plate user exposes hundreds of plates on a journey, rarely making two exposures on the same subject, and deferring all development until he gets back, a few such "mysterious markings" would be sufficient to drive the make of plate on which they occurred right off the market, and in the Barnet Works accordingly, the most elaborate series of precautions are observed to prevent the slightest chance of anything of this sort occurring.

Needless to say, every piece of glass used in the manufacture of the Barnet plates is new.

It is more. It is carefully selected and preserved from risk of any accidental soiling, and immediately before use is passed through machines designed to give it a cleansing, beside which all ordinary washing operations seem absurdly perfunctory. The result is, that when the glass passes through the coating machine it is in a condition of purity, unapproached in any other manufacturing operation whatever, and the users of the plates so made are able to place in them the most complete confidence.

FORTHCOMING COMPETITIONS.

September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

FORTHCOMING EXHIBITIONS.

September 14-15.—Cambridge Photographic Society. Hon. T. J. Sowdon, "Sunny Side," Guest Road, Cambridge.

September 16 to November 5.—Photographic Salon, Dudley Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Graphic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Sec. E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's ninth Exhibition, New Gallery, Regent Street, London. Sec. A. W. W. Bartlett, 66, Russell Square, London, W.C.

September 29.—Beverley Photographic Society. Hon. Sec., Morley.

October 15-29.—Coatbridge Photographic Association. Hon. Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.

October 18; 19; 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Kettering.

October 19-20.—Isle of Wight Photographic Society. Hon. J. Howard Burgess, 53, Pyle Street, Newport, I.W.

October 19-22.—Rotherham Photographic Society. Hon. Sec. C. Hemmingway, Tooker Road, Rotherham.

November 2; 3, 4, 5.—Newark Photographic Exhibition. Sec. L. C. B. Appleby, Barnbygate House, Newark.

November 2-23.—Plymouth. Hon. Sec. Photographic Soc. Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.

November 3.—Frome M.I. Photographic Society. Hon. Sec. B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Sec. Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 15-19.—Sunderland Camera Club. Hon. Sec., Seiby 52, Frederick Street, Sunderland.

November 17-18. Braintree and Bocking Camera Club. Sec. W. H. Tilton, 81, High Street, Braintree, Essex.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, I. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. G. W. Simmers, Aberdeen House, Ramsgate.

November 25-26.—Ilford and District Photographic Society. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmar Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Leinstown, Glasgow.

December 2-8.—Southsea Photographic Society. Hon. Sec. F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17. First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102 West 161st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Scott Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

June, 1905.—Northern Photographic Exhibition. Secretary, F. Issot, 62, Compton Road, Harchills, Leeds.

New Apparatus, &c.

Stamp Midget Camera and Printing Frame. Sold by H. Tress, 33, Oxford Street, London, W. This camera is made to produce either six or twelve negatives of great sitters with one lens. Only one dark slide used for both

pictures; therefore, without any further outlay for extra slides fittings, the operator is able to produce pictures $2\frac{1}{2}$ ins. by 1 in. at will; either vertical or horizontal. Size of plates

$2\frac{1}{2}$ 5-16ths by $1\frac{1}{2}$ ins., which is a standard size, and can be used in all makes. Size of bromide paper $6\frac{1}{2}$ by 4 $\frac{3}{4}$.

is a well-made piece of apparatus, and should be extremely useful to those photographers who make a special line of stamp and get photographs.

"PHOTOGRAPHING British Mountains" is the title of an interesting article in the current number of "Cassell's Magazine." It is written by Mr. George O. Abraham, the well-known mountaineer. Illustrations are excellent, and show that the aspiring climber does not seek the Alps for arduous struggles and exciting adventures. Abraham relates many of his experiences, both amusing and serious, and disposes of the popular fallacy that "climbing" photographs always make the difficulties appear greater than they are. He says:—"It is scarcely ever possible to make a photograph show the actual difficulty of the leading climbs, for in nearly every case the camera has to be tilted upwards, and thus the idea of height is lost. The ideal position is on a level with the subject, and how often one yearns to be swung out twenty or thirty feet from the crags into space. But the days of aerial locomotion are not yet. In some cases it is possible to climb up a steep buttress and waylay a friendly party in an adjacent gully; but plans need to be arranged beforehand, otherwise one party may be out before another arrives, and the two parties often lose each other."

Commercial & Legal Intelligence

ESME COLLINGS, LIMITED (Photographers, London, Brighton, and Liverpool).—A first mortgage debenture, dated August 12, 1904, to secure £1,000, charged on the company's undertaking and property, present and future, including uncalled capital, has been registered. Holder—Mrs. S. A. Fentum, 78, Westow Hill, Upper Norwood.

THORNTON, Limited (Photographers, Altrincham).—Issue on August 26 of £250 five per cent. debentures, part of a series created same date to secure £1,000, charged on the company's property, present and future, including uncalled capital. Holders—Mrs. E. M. Thornton, Rokeby, Altrincham; and J. E. Thornton, Rokeby, Altrincham. No trustees.

SCOTT'S STUDIOS, LIMITED.—This company has been registered with a capital of £2,000 in £1 shares. Object, to carry on the business of photographers, photo-mechanical printers, manufacturers of and dealers in articles used in the photographic trade, optical appliances, scientific instruments, electrical goods, etc. No initial public issue. The first directors are W. T. Scott, C. T. Fox, and R. S. Dick.

MIDLAND COUNTIES PHOTO COMPANY, Limited.—This company has been registered with a capital of £5,000 in £1 shares. Object, to acquire from H. Spencer the entire interest in the business carried on as the Midland Counties Photo Company, and to carry on the business of photographers, photographic artists, portrait painters, etc. No initial public issue. Registered without articles of association. Registered office, County Chambers, Corporation Street, Birmingham.

ROTARY EXPANSION.—The Rotary Photographic Co., Ltd., notify us that the growth of their business is forcing them to vacate their premises at 14, New Union Street, Moorfields, and that they are now in process of removal to 12, New Union Street, precisely opposite to the quarters which they have found insufficient. No. 12 is one of the large and solemn, if not ornamental, City blocks, and the Rotary Company are occupying the whole of it, seven floors. Concurrently with this expansion, a second floor is being placed on the company's factory at West Drayton.

PARR AND COMPANY, LIMITED.—This company has been registered with a capital of £2,000 in £1 shares. Object, to acquire the business carried on by C. J. Parr and G. J. Jack, at 130, Westminster Bridge Road, S.E., as Parr and Company, to adopt an agreement with the said vendors, and to carry on the business of manufacturers of sensitised photo printing papers, draughtsmen, designers, specialists in art metal designing, colouring, and photo printing, etc. No initial public issue. The first directors are C. J. Parr, A. T. Howe, and G. J. Jack. Qualification one share. Remuneration £30 per annum.

AXTON, Limited.—This company has been registered with a capital of £10,000 in £1 shares. Object, to acquire the business carried on at 47, and 49, Newington Butts, S.E., as the Axton Company, to adopt an agreement with F. E. Coe and W. E. Scott, and to carry on the business of manufacturers of and dealers in machines and instruments, for musical entertainment, instructive, surgical, and scientific business and other purposes, including phonographs, autoscopes, biographs, mutoscopes, cameras, automatic machines, etc. No initial public issue. The first directors are F. E. Coe and W. E. Scott. Qualification 100 shares. Remuneration as fixed by the company.

PHOTO DEVELOPMENT SYNDICATE, Limited.—This company has been registered by Jordan and Sons, 120, Chancery Lane, W.C., with a capital of £2,000 in £1 shares (one founder's). Object, to adopt an agreement with E. Falla, A. Eldridge and F. J. Wood, and to carry on the business of manufacturers of and dealers in photographic apparatus, materials and accessories, printers, lithographers, publishers, bookbinders, booksellers, stationers, etc. No initial public issue. The first directors (to number not less than five nor more than seven) are E. F. Collins, W. A. Eldridge, E. Falla, G. Reeves, F. J. Wood, and L. F. St. John. Remuneration 10 per cent. of the net profits, or £100 per annum (whichever is larger) divisible. Registered office, The Company's Works, Park Road, Tunbridge Wells.

WALTURDAW COMPANY, Limited.—This company has been registered with a capital of £10,000 in £1 shares. Object, to acquire

the business carried on at 3, Dean Street, Holborn, as Turner, Dawson, and Howard, and to carry on the business of manufacturers of and dealers in cinematographs, animated picture machines, photographic apparatus, photographs, and films, photographers, art dealers, printers, publishers, public entertainers, and caterers, installers of electric gas, lime and other light, magic lantern manufacturers and dealers, opticians, manufacturers of and dealers in scientific instruments, etc. No initial public issue. The first directors (to number not less than two nor more than seven) are J. D. Walker, E. G. Turner, G. H. J. Dawson, and E. Howard (joint managing directors with £250 each per annum), G. H. Turner (chairman with £100 per annum) and L. de Beaumont-Klein. Qualification 25 shares. Remuneration of ordinary directors, one guinea each per board meeting. Registered office, 3, Dean Street, W.C.

A PHOTOGRAPHER'S DOWNFALL.—At the Guildhall Police Court, on Thursday last, Henri Tradeau (30), of 11, Woodstock Road, Shepherd's Bush, a photographer in the service of Mr. Green, 81, Aldersgate Street, was charged on remand on a warrant, with stealing, during the last twelve months, seven lenses, a half-plate camera, and other property, to the value of £105 9s. The accused pleaded guilty. A quantity of the goods were traced to an auction mart. A strong appeal was made for mercy on the ground that the prisoner had not given way to any kind of vice, that he was a sober, industrious man, and that he had made all the reparation in his power, and that were any sentence passed on him he would find it very difficult to again hold up his head or get anything to do. The Alderman said he would give weight to the appeal, but he had a duty to perform—painful though it was. He hoped the justice of the case would be met by sending accused to prison for three months with hard labour. The goods recovered were ordered to be given up.

AN "ART" PHOTOGRAPHER'S FRAUD.—On Thursday, at Frodsham Sessions, William Nichols, a well-dressed and educated young man, who described himself as an art photographer, was charged on remand with obtaining money by false pretences from George Morris, Mary Ann Howard, and Annie Jones. His *modus operandi* was to visit houses, preferably large residences, and to prey upon servants, soliciting work in enlarging or taking photos. In all cases he demanded some payment on account, and gave a receipt which bore the address of 56, Bewsey Street, Warrington. Prisoner, however, once hold of the money, made himself scarce in that locality and was never again heard of. He was eventually arrested at Sligo and brought back. His excuse was that he was hard up and could not get work, and took small amounts from each individual, so as to enable him to travel from town to town in his futile endeavours to obtain employment. Having a previous conviction recorded against him he was sentenced to nine months' hard labour, three months for each indictment.

THE DARK-ROOM LIGHT.—A recent issue of the "Photo Gazette" gives a formula for staining paper to be used as a filter for the dark-room light. It is, according to the "Bromide Monthly":—"Alcohol, 1,000 ccs., or 35 oz.; auramin O, 5 grms., or 80 grs.; safranin (Merck) 5 per cent. alcoholic solution, 100 ccs., or 3½ oz. The paper is to be soaked in this spirituous liquid for five or ten minutes. The formula and others of a like kind should be useful to bromide workers, to whom plenty of light in the developing room is of the first importance. The small lamp with a glass of about 10 by 8 inches is much too small a size, and usually the light is too red and deep. A bright yellow can be used with safety for bromide work, and the better the illumination, so long as it is safe, the better the work will be. The home-made lamp—constructed from a disused sugar-box or packing-case—is more suited to practical requirements than any commercial lamp. One form of lamp which we have seen was made from a couple of child's hoops, or, more correctly, from a hoop and a half. The half of one hoop was sprung into a complete and somewhat smaller hoop, so as to form the skeleton of a dome, which dome was covered, base and all, with canary fabric. An incandescent lamp was hung in the interior, and the whole concern suspended close to the ceiling of the dark-room, whence it filled the apartment to every corner with a safe and agreeable light. The same plan might be adapted to oil or gas.

News and Notes.

LAST DAY for the R.P.S. Exhibition.—Pictures for the Photographic Society's Exhibition will be received at the Gallery, Regent Street, up to 6 p.m. to-day (Friday) if delivered by hand.

THE Lantern Slide Exchange Club.—The secretary of this has asked us to announce that there are some vacancies for members. Full particulars will be supplied by Mr. J. S. Hammett, Mutley House, Plymouth.

THE Prospectus and Entry Form of The Glasgow Eastern and Fife Photographic Association's Exhibition is to hand, and we note efforts are being made to secure a big show. There are three classes (any subject), and the judges will be Messrs. Wm. C. and Arch. Cochrane. The last day for entries is November 14.

A NEW Method of Mounting Prints.—Messrs. Bayer have introduced a new method of mounting prints, demonstrated by Mr. at a meeting of the French Photographic Society. A very powder—"colle en poudre"—contained in a wide-mouth bottle, a sieve-like top, is evenly dusted over the moist print, which is laid on the mount and rubbed down in the ordinary way.

THE Exhibition of Process Engraving, to be held in the autumn at the Victoria and Albert Museum South Kensington, will in photogravure, photo-lithography, and kindred processes of reproduction by means of photography, as well as a special section devoted to the half-tone colour process, limited to four printings. The time for the reception of exhibits has been extended to the 30th inst.

ON Tuesday morning at nine a fire broke out in a shop window in the Victoria and Albert Museum, High Street, its origin being somewhat unusual. The rays of the sun played on a magnifying glass in the window, with the result that some celluloid photographic development dishes became ignited. The shop was shut, but the flames in the window were noticed by passers-by, one of whom got through skylight and extinguished them.

SALE of the Late Dr. Isaac Roberts's Observatory.—The telescope and general apparatus used by the late Dr. Isaac Roberts, F.R.S., for the production of his famous celestial photographs, is to be sold; also the observatory, house, and grounds (about 4½ in extent), Starfield, Crowborough, Sussex, which is 800 feet above sea-level. The whole is to be disposed of as it stands or the scopes and apparatus may be sold separately.

JARROW Camera Club.—The members of the Jarrow and District Camera Club inaugurated their winter session at the club on Saturday last, Jarrow, last week. Mr. E. W. Penman, the President, occupied the chair, and there was a large attendance. Twelve members of the club organised a very successful exhibition of photographic works in the Mechanics Hall, and the arrangements are in progress for a similar display during the coming winter.

THE Hull Photographic Society paid a visit to Flamborough on Saturday afternoon last. Shortly after arrival the wind grew strong and a heavy sea prevailed for about three hours, and in consequence the visitors were in their element, taking advantage of the fine and the wave studies. The next outing is to Paul, September 16, and the last to Barrow Haven October 1.

THE South London Photographic Society are starting their winter evenings on Monday, October 10th, and this year have decided to admit free of charge anyone who likes to make application to the secretary. The members who take charge of these evenings have thorough knowledge of their own particular subject, and will attempt to show "How it is done" in a simple and practical manner. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, will be pleased to send programmes and full particulars.

THE Frome Photographic Society have arranged their exhibition to be held at the Mechanics' Hall on Thursday, Friday, and Saturday, November 3, 4, and 5. There are eight open classes and one special class, open only to residents of the town and neighbourhood. Mr. C. Barrow Keene, of Derby, and F. M. Sutcliffe, of Whitby, have been retained to appraise the exhibits and silver and bronze medals or plaques will be placed at their disposal to be awarded in

Schedules and all other particulars may be obtained on application to the hon. sec., B. J. Mitchell, 3, Willow Vale, Frome.

LEOPOLD as Art Patron.—The Board of Education have informed, through the Foreign Office, that an exhibition of arts, under the patronage of the King of the Belgians, will be held in a special pavilion within the exhibition grounds of the Universal and International Exhibition, to be held in Liege in 1905. Full particulars as to the conditions attaching to exhibits will include paintings, sculpture, engravings, photography, architectural designs—are given in the official regulations, which have been obtained on application to the Consul-General for Belgium, at St. Helens, E.C.

Death of Captain M. Horace Hayes, the well-known authority on photography and their management, has occurred at Southsea. Captain Hayes was employed by the Government during the South African War, and was the writer of many books on veterinary subjects, and was the author of a "Student's Manual of Tactics." He was at one time Major in the Royal Artillery and saw considerable service with the Bengal Artillery. Captain Hayes will be remembered by many of our readers as having devoted special attention to photography, on which he had several papers before the Royal and other societies.

Grief having to report the death of Mr. Austin Joseph King, etc., who died at Tenby on August 28. The deceased gentleman's deep love of science bespoke him an attentive hearing at the London societies—photographic and otherwise. From the time of his formation and continuance of the Bath Photographic Society in 1903 he was probably the most active worker and largest contributor, scientifically and socially, to its work. He was not unknown to the public, and it is doubtful whether the Bath meeting could have been held in 1891 without the active co-operation the members obtained through his assistance.

OUR writes: "Your correspondent, 'Amidol,' appears to be suffering from a rather widely spread, shall I say disease, at the present moment. I myself have been consulting a doctor and various remedies over a like complaint, and the only alleviation I can find from the use of burning and irritation of such lumps on my face, hands, and the cream sold under the name of 'Icilmia.' I may state that it does not appear to quite cure the spots, but it takes away the pain. I might mention that I know at least a dozen people who are suffering from this complaint, and not one of them has anything to do with chemicals of any description."

We have received a second edition of "Ferric and Heliographic Processes," by George E. Brown, F.I.C. The text has been largely revised and brought up to date. Plans for printing copies on blue paper are a new feature of chapter 3, and the chapters on the new process embody the recent advances in this process. It is hoped that before the volume will be found useful both by photographers interested in the iron processes and architects, draughtsmen and others who superintend the copying of drawings and prints. A number of actual prints are issued as supplements. The work should be in the hands of everyone interested in this branch of photographic printing.

THE ENLARGING EASEL.—Those who are undertaking enlarging, but inexpensive methods of preparing an enlarging outfit make a note of a very simple plan of fixing the easel in position recommended in the "Bromide Monthly." Not the least of its merits is that it permits of the easel being set up or taken down in a moment. A "screw eye" is screwed into each side of the easel about an inch from the top, and through each is passed a stout wire. The two ends of each rubber are fastened to the table on which the easel stands, being secured in each case to points about a foot in front and behind the easel. The latter is thus held firmly in position in pretty much the same way as the supporting poles of a camera are secured.

PRELIMINARY VISIT.—The "Johannesburg Star" states that on a Saturday afternoon two policemen, standing near Cartwright's Capetown, noticed smoke issuing from a window on the floor of Duncan's Chambers, in Sheridan Street. Rushing into the building, they dashed into a room through an open doorway, from which smoke was still issuing, and there found a number of ladies sitting quietly waiting for a group photograph. It appeared that an enterprising amateur was taking a flashlight photo of the group, and that the smoke given off from the burning magnesium

wire had gone out of the window. Further excitement was caused by the arrival of the fire brigade, much to the amusement of the crowd which had collected.

THE Committee of the Northampton Museum and the Photographic Section of the Natural History Society are discussing the holding of a very important photographic exhibition, of a competitive character and open to all the world, early in 1905. The exhibition will take place in the Municipal Galleries from February 17 to 25, 1905. A very strong executive committee, under the presidency of Mr. H. Manfield, J.P., has been appointed, consisting of Alderman Campion, J.P., Councillors Hannen and Gribble, Messrs. G. Scriven, C. H. Dorman, A.R.I.B.A., with Messrs. E. J. Felce and W. J. Lewis as the hon. secs. The last occasion on which such an exhibition took place was in 1899, and every effort will be made to ensure even a more enjoyable, representative, and successful show than on that occasion.

We have recently seen specimens of the new Rotary Stripping Pigment Film for three-colour photography. The process seems to be simplicity itself, and the results achieved appear to be as good as could be desired. In addition to this, no costly apparatus for the production of either the original negatives or the resultant prints is necessary—a fact that should make this method of producing photographs in natural colours extremely popular. We understand that Mr. Sims, whose name is already well known to most of the English photographic societies as an able demonstrator and lecturer on behalf of the Rotary Company, intends demonstrating the new process during the coming winter season. Secretaries of societies should take note of this, and as Mr. Sims still has a few vacant dates, should endeavour to secure his services for a very interesting item in their list of fixtures. A line to the Rotary Company, New Union Street, Moorfields, E.C., will bring all particulars.

THE Hon. Sec. of the Photographic Club writes from 49, Princes Road, Wimbledon, London, S.W.:—Owing to the removal of the club to premises where there is no accommodation for a library and museum, the committee have decided to dispose of the club's unique collection of books upon photography, and of apparatus and specimens illustrative of photographic progress. Should this fact interest you I shall be pleased to forward you a complete catalogue of the books, etc. The library consists of between 400 and 500 volumes, and includes bound sets of the *BRITISH JOURNAL OF PHOTOGRAPHY*, "The Photographic News," "The Amateur Photographer," "The British Journal Almanac," "The Year Book of Photography," and other periodical publications, Daguerre's "History of Photogenic Drawing, 1839," "Fox Talbot's Pencil of Nature, 1844," "Archer's Collodion Process, 1854," etc., etc. The library is particularly rich in early books on photography. Among the objects in the museum are a complete set of Daguerreotype apparatus, an original Daguerreotype, by Daguerre, and many fine specimens of the same process, some fine examples of ceramic photography, by Lafon de Camarsac and by Joubert, calotype negatives, experimental reliefs, and other relics of the Woodbury type and Stannotype processes, by Woodbury, and many other historically interesting specimens.

A new photographic club has been formed in Victoria, Australia, named the "East Malvern Amateur Photographic Club." Its membership is open to ladies and gentlemen interested in photography, and its object is the study and practice of artistic and technical photography by means of papers, demonstrations, camera outings, lantern nights, competitions, and such like. The first general meeting of the club was held at St. John's Schoolroom Finch Street, East Malvern, on July 22, and was well attended. The rules of the club were adopted, and the election of office-bearers for the ensuing year resulted as follows: Patron, Hon. Wm. Knox, M.H.R.; president, Rev. J. B. Gason; vice-presidents, Councillors Alexander McKinley, C. D. Lloyd, and F. Stone, Esq.; committee, Messrs. D. H. Fox, J. S. Mercer, F. J. Muirhead, A. E. Walcott, and S. H. Wilson; auditor Mr. H. Spittle; hon. secretary and treasurer, Mr. Sydney Fox. Monthly meetings of the club will be held on the first Friday in each month, for which an interesting syllabus, contributed to by well-known experts in photography, is in course of preparation by the committee. The subscription has been fixed at gentlemen 5s., and ladies 2s. 6d. per annum. The hon. secretary's address is "Almalea," Dandenong Road, East Caulfield, Victoria. Literature syllabus, etc., forwarded by kindred institutions to the hon. secretary would be deemed a favour.

Correspondence.

A BENEVOLENT FUND FOR PHOTOGRAPHERS.

To the Editors.

Gentlemen,—Mr. Snowden Ward's suggestion to resuscitate the Photographers' Benevolent Association is one which supplies a good subject for thought and discussion. It is no credit to the craft that the two attempts which had hitherto been made to provide a permanent agency for the relief of distress amongst those who practise photography professionally should have failed by reason of the neglect of photographers themselves. I began subscribing to the association when Mr. Harland was secretary, as far back as 1888; on more than one occasion I have passed the hat round for it; and for some years I acted as an officer. My case is not solitary. There are many who, like myself, helped the association from purely unselfish motives, and had been mortified at the futility of the earnest efforts made to persuade photographers to keep the thing alive. It is, however, a consolation to know that the money subscribed was always well administered; that many deserving cases of distress were relieved, and that there are still to be found non-professional photographers able and willing to assist the bread-and-butter man if only he will evince some disposition to help himself. The work, I think, is to Mr. Lang Sims, a prominent member of the P.P.A., whose keenness in the good cause remains, I hope, unabated.—I am, yours, etc.,
A WELL WISHER.

September 4th, 1904.

To the Editors.

Gentlemen,—I have read your able articles on the above subject, and as an old member of the late Benevolent, I quite agree with you that something should be done at once to reform the same; but it is a question if it would meet with much success, unless photographers and assistants put more heart and soul into the affairs of such a society. I myself advocated some years ago, in the *BRITISH JOURNAL*, the formation of the same on sick benefit society lines, and I still feel sure that if this could be done success would attend any efforts that were made by a committee formed for the purpose. My reason for writing is, with your kind permission of space in the *BRITISH JOURNAL*, to put before my fellow professionals and assistants the working of a society in Stroud, of which I have been for some years a member. It was founded by the late George Holloway, M.P., and a small band of working men in, I believe, 1875, and year by year has made rapid strides, and, as you will see by the balance sheet enclosed, is at the present time in a very flourishing condition. The same is called the Conservative Working Men's Benefit Society, but is not in any sense a political society, as any person of good character can join, irrespective of politics. Young men may join at 17, and can pay for one share till 21, when they can obtain two shares. Members can have as many as three shares, but must be earning its equivalent as wages. Members pay 1d. per day per share till they are 30 years old, when their contributions are increased ½d. per share per year for the remainder of the time they are members. Sick pay is paid them as follows: Half share, 5s. per week; one share, 10s. per week; one share and a half, 15s.; and two shares, £1; three shares, 30s. The moneys of the society are invested by an investment committee and the interest equally divided annually among the members and re-invested at 4 per cent. after payment of sick pay, management expenses, etc. £1 5s. per share has for some years been paid as dividend. Should a member die before he has accumulated £10 in the society this is made up by levy among the members. Should a member's wife die this is also made up by levies. Members cease paying member's levy on having £10 standing to their credit, but all pay wife's levy. Should a member wish to withdraw his fund he can do so by forfeiting his last two years' dividends, but can still remain a member on satisfactory proof of good health. On attaining the age of 65 members must either withdraw all their funds from the society, or,

if preferred, can purchase an annuity for the rest of their life. John Dorington, I believe, has done this on his own life incentive to the members to become thrifty. The working society was, I believe, brought before Parliament by Sir John Lubbock, M.P. for Tewkesbury, and Mr. Cripps, K.C., M.P., as one of the old age pension scheme then before the House. To members out of employment, a small levy could be made, members, or a sum could be set aside for this purpose. Objections may be taken that many photographers belong to Foresters' Oddfellows. True, but many do not; and what about the young assistants? I myself have been the means of getting four of my assistants to join this society. Among the many hundreds of thousands of workers in photography, including dealers, assistant plate makers, etc., surely such a society could easily be formed on a good, sound commercial basis. I should much like to have the opinion of your various readers on the matter, and I am of opinion that such a society could be formed. I should like to do all in my power with others to help it on. May I copy the motto of this society to photographers' notice: "God help those who help themselves"? I should like also to say there is a society on the same lines for women.—Thanking you in anticipation of the insertion of this letter, I remains, Sirs, yours respectfully,
J. H. SIMS.

Gloucester, September 5th, 1904.

PATENT EXAMINATIONS.

To the Editors.

Gentlemen,—The Board of Trade has just issued an order, brought into force on the first day of January next, the Government examination system for patents set forth in the Patent Law of 1900 from January 1st, 1905, reducing the period of provisional protection from nine months to six. The system of examination thus introduced is much less perfect than those of other countries, as the examination has merely to search through the British patents of the immediate preceding fifty years to see if in these there be, in his opinion, anticipation of the invention set forth in the complete specification. This report is forwarded to the Comptroller, and if the Comptroller is of the opinion (from this report) that the invention is partly or wholly anticipated, the applicant is informed of the anticipation, and of the option of a personal hearing, or of amending the specification to the satisfaction of the Comptroller, or in default of either, the Comptroller determines whether a reference to any, and if so, what prior specifications must be made in the specification by way of notice to the applicant. Against his decision there will be an appeal to the Law Office. The Examiners' reports will be kept strictly secret from all but the applicant and his agent, but this examination must not be held in the case of a guarantee in any way the novelty of the invention or the validity of the patent, as, of course, the prior publication of the invention in other documents open to the public in England prior to the date of application, or the prior public use of the invention would be fatal to the validity of the patent as the publication of the invention in a prior British specification.—Yours truly,

W. P. THOMPSON AND CO.,
Chartered Patent Agents.

6, Lord Street, Liverpool,
September 1st, 1904.

PHOTOGRAPHIC COPYRIGHT.

To the Editors.

Gentlemen,—As the question of photographic copyright is so much brought before your readers under its various aspects, I cannot think that the following extract from the "Tatler" regarding recent pretty child competition may be interesting in showing progress which has been made in establishing the rights of photographers in work taken at their own initiation and expense. In giving various particulars, the editor goes on to say that:—"Photographs may be taken either by professional or amateur photographers, but in all cases they must be non-copyright. The benefit of those who perhaps do not understand what this means, repeat what I said in a previous issue. Roughly speaking, concerning photographs is this: If you have a photograph taken by a professional photographer and pay him for it the copyright is

to say, you can dispose of it for publication as you wish. If not pay for the taking of the photograph the copyright is the property of the man who took it, and he can refuse permission to have it published. We reserve to ourselves the right to publish without payment any photograph or photographs received in connection with competition, and the sending to us of a photograph by any communication must be taken as implying full permission for us to publish it."

Thanking you in advance for your kind courtesy, I am, Sirs, yours truly,
A MEMBER OF THE P.C. UNION.

I have a suggestion to offer our correspondent. It is that he should make a rule of informing those persons whom he photographs to inform them that the copyright is vested in him, and that if the use of the photograph parts with it for reproduction to a third party the latter runs the risk of being pounced upon for fees he did not contemplate incurring. Quite recently we reproduced in these columns a photograph of a gentleman by his permission, and subsequently received a demand for payment from the author of the above letter. I am sure that if the original of the photograph had been made that it was not his copyright he would have told us so, and we should then have used another photograph of him which was in our possession, and for which we need not have paid. There is a splendid situation: the Journal and its present Editor, staunch supporters of the Photographic Copyright Union for years, being severely penalised under one of the rules of that body!!!—EDS.

STALE PLATES

To the Editors.

Gentlemen,—A few days since, being out of a certain size plate, I called on a local photographic dealer for some. They turned out very bad plates, a foggy, miserable image. The work I went to do was an absolute failure, and it cannot be done again. What is my remedy? The dealer says he is not responsible, as no warranty is given. He acknowledges the plates are 14 or 15 months old. The work was done by one of the best makers and backed.—Yours truly,

ENQUIRER.

September 2nd, 1904.

I shall be glad to have the opinions of our readers on this knotty question.—EDS. B.J.P.]

Patent News.

Following applications for Patents were made between August 1st and August 27, 1904:—

1. Stereoscopic Camera.—No. 18,331. "Stereoscopic Camera." Complete specification. Theodor Schroter.

2. Improvements in or relating to shutters for photographic cameras.—No. 18,454. (Frank A. Brownell, United States.) Kodak, Limited.

3. Improvements in or relating to focusing devices for photographic cameras. (Frank A. Brownell, United States.) Kodak, Limited.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

A. WILDMAN and Co.—We advise you to accept the guinea offered.

POSTCARDS.—"AJAX" says: "Please let me know the address of a postcard firm who print imitation P.O.P. postcards from customers' own negatives or blocks." In reply: Try Morgan and Kidd, Richmond; or Wyndham and Co., Acton, W.

BOOK WANTED.—"T. L. F." writes: "I shall be very glad if you will recommend a complete practical book on picture-framing, mounting, etc." In reply: "Mounts and Frames, and How to Make Them," by Lambert. No. 20 of "The Photo-Miniature" on "Trimming, Mounting, and Framing."

MOUNT MAKING.—"MOUNTS" write: "We should be glad if you would give us the address of a firm which supplies machinery for making photographic mounts, blocking, etc.?" In reply: We should surmise that any of the houses that make a speciality of bookbinders' appliances would supply your wants.

COLOURING PHOTOGRAPHS.—"PHOTO-ARTIST" asks: "Will you kindly let me know what medium is used for painting photographs, both on matt, enamel and burnished prints?" In reply: Colours for the purpose are sold by all the large dealers. No medium is required with them. Or ordinary water colours may be employed.

EMULSION.—F. LLOYD says: "I should be greatly obliged if you could inform me if you know of any firm or person from whom I could obtain a bromide or other emulsion readily mixed for immediate use?" In reply: We know of no firm that supplies ready made gelatine emulsion.

DICTIONARY OF PHOTOGRAPHY.—F. ESSAM asks: "Kindly let me know what the price of 'Dictionary of Photography' is, and who are the publishers. Does it contain good formulae?" In reply: E. J. Wall's "Dictionary of Photography" is published by Messrs. Hazell, Watson, and Viney, Long Acre, W.C., price 7s. 6d. The formulae will be found very useful.

DESCRIPTION WANTED.—"D. R. M." writes: "Would you kindly tell me the kind of paper the enclosed photo is on, also the manner in which it is toned?" In reply: The print seems to be a platinum toned one, on collodio-chloride paper. We could not say for certain, however, without injury to the print by testing. It has been returned to you as desired.

DISPOSAL OF NEGATIVES.—"JUDITH" asks: "Could you tell me the best way of disposing of a large quantity of old negatives from quarter-plate to 15 by 12?" In reply: The only suggestion we can offer is that you advertise them for sale. If they are negatives of portraits you have been paid for taking you have no right to dispose of them without the sitter's consent.

RETOUCHING.—"RETOUCHER" asks: "Will you let me know what you think of the retouching of the enclosed prints, and what class of work would you call the prints on the whole?" In reply: The work is fairly good, supposing the likenesses have not

been altered. Of that we cannot judge, as prints from the untouched negatives were not enclosed for comparison.

DAMAGED PLATINOTYPE.—A. G. NEWACK asks: "Will you be good enough to tell me what is the best way to prevent the surface rubbing in sepia platinotype prints, as the enclosed; is the use of too strong acid likely to cause this?" In reply: With careful handling in the manipulations the surface will not be damaged. The use of too strong an acid bath would have a tendency to render the surface of the prints tender.

PHOTOGRAPHING CLOTHS.—"ALEXANDRIA" writes: "Is there any kind of stretching frame procurable, or method in use, whereby I can hang up cloths of a large size, say 9ft. by 7ft., so as to have them perfectly tight and even over the surface, in order to photograph them?"—In reply: We know of no such stretching frame. We expect you will have to get one made—such as a background frame—and strain the cloth on it. Could you not back them on a wall of the studio?

RESTRAINER.—A Correspondent writes: "Re reply to 'Restrainers,' page 779, bromide ammonia is chiefly used with pyro-ammonia developer, and doubtless this is what 'H. B. C.' uses, and, of course, if he uses with pyro soda he will liberate free ammonia, which will accelerate instead of restrain. Bromide of potassium, of course, is right enough for either developer—pyro-ammonia or pyro soda—but not bromide of ammonium, which only does for the former."

REDUCER WANTED.—"W. H." says: "I enclose a print, which lacks detail in the apron and collar. Will you kindly give formula of the best reducer—i.e., one that will reduce the high lights without touching the shadows? The negative is very thin, but too dense in the apron, etc." In reply: One of the best reducers for the purpose is a solution of persulphate of ammonia; about a 5 per cent. solution is a suitable strength to use.

RETOUCHING.—"A. H. D." (Wilts) asks: "(1) Would you kindly pass your opinion of the retouching on the enclosed prints? I have had only a few lessons and would like to know how I am progressing. (2) Could you recommend me a useful book of instructions?" In reply: (1) Our opinion is that the retouching, like the photography, is about as bad as it well can be. Could you not realise this yourself? (2) The "Art of Retouching," by Robert Johnson.

ARTIFICIAL LIGHT.—"ONE IN THE DARK" asks: "Is it possible to make a good negative of full length figures in the studio at night time with mixed gas? If so, how many jets would be required for taking a group?" In reply: We do not think you would be very successful in taking groups with the lime-light, unless, indeed, you had a good number of jets. We think you would do better to employ magnesium, which yields a more actinic light.

CAMERAS.—"M. E. N." writes: "I would feel very thankful if you would kindly let me know what kind of camera it would be best for me to get to make a start for taking photos of persons in the house, and also for taking sketches outside for sale." In reply: Almost any portable camera will suffice for the work. We should advise you to get catalogues from two or three of the dealers, and from them select what will suit your purse the best for the size you desire.

STRIPPING FILMS FROM BROKEN NEGATIVES.—"P. R. D." asks: "How can I strip a film from a broken negative?" In reply: We have given this information on many occasions in this column. Soak the negative in a 10 per cent. solution of formaline for ten minutes, rinse, and then immerse in water, 1 oz.; alcohol, 1 oz.; glycerine, 20 drops; hydrofluoric acid, 40 drops. Allow the negative to soak in this till the film lifts at the corners, then transfer to a dish of clean water, coax the film off, and transfer to a sheet of glass coated with gelatine. An unexposed fixed plate may be used.

VARNISHING FILMS.—A. W. WOOD asks: "Can celluloid films (negatives) be varnished, if so, how, and can they be retouched?" In reply: The best way of varnishing celluloid films is to use

an aqueous shellac varnish and dip them bodily in, and hang up to drain and dry. Such a varnish can be made as follows: Shellac (bright orange), 4 ozs.; water, 20 ozs.; heat to boiling point, and add saturated solution of borax, stirring well till the shellac has nearly all dissolved, then to stand for two or three days and filter, or else filter through animal charcoal. The films can be retouched in exactly the same manner as glass negatives.

SPOTTY PRINTS.—W. BELL says: "I shall be grateful if you kindly examine the enclosed prints. When I received a sample of paper I complained as to the colour. The firm that the same is the natural tint, which finally tones out seems to me the paper has some kind of impurities to do with. The spots on the finished prints appear in a few time. I have used C. C. for years and have never had an experience. I may mention that the paper is the product of the firm. I think I shall be quite justified in refusing to print this sample, as my mounts this week will all be wasted, one cannot tell where such results will finish. I may say I always take care about the washing, and superintend the printing. In reply: Spots such as those on the prints may arrive several due to the manipulations. We think it improbable that they are due to the paper itself, which seems all right."

STUDIO QUERY.—"STAMPS" asks: "Will you please advise me what kind of portable studio I ought to put up in the yard, and of which I enclose. Owing to building rules of Corps I think I shall only be able to use a space of about 13 feet. Do you think this will be ample for general portrait work, and how would you advise building it—the at the garden-wall end, or the coal-place end? I intend the north-west side will be the side to light from. The amount of window space would you advise, and can groups in so small a studio, or shall I be limited to cabinets? I also want to use it for stamp photos by a light." In reply: Eighteen feet will be very short for groups, unless you can take the camera out of doors, perhaps, you would be able to do so. We should recommend you to get Bolas' book, "The Photographic Studio, its construction, etc." That will give you much practical information on the subject.

A CURIOUS state of things was revealed at Cambridge in connection with the N-rays supposed to have been discovered by M. Blondlot. The German physicists have failed to find the N-rays, and Lummer, of Charlottenburg, distinctly threw doubt on their existence. Speaking in the Physics Section, he asked those who had tried to detect these rays to hold up their hands, and fifteen members responded to the invitation. The doctor then asked how many had attained a positive result; one hand only was held up. The case is strange, if not unprecedented. In France the event has been accepted, the original investigators' experiments have been repeated, and the French Academy of Sciences has awarded a medal to M. Blondlot; meanwhile, in Germany, and, we believe, in every other country, the experiments have had negative or doubtful results, and scepticism prevails in regard to the whole matter.

NOTICE TO ADVERTISERS.—Blocks and copy are received to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

A forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,604 pages, the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose continuing the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, the year's advances in theory and practice will be recorded.

The frontispiece of the ALMANAC will consist of a portrait study specially taken by Mr. Furley Lewis, a member of the Royal Photographic Society's Exhibition, 1903.

* IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that this year's entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1st—next—a fortnight earlier than usual, so as to be well in advance of the Christmas publication season.

EX CATHEDRA:

Aggressive Amateurs.

We hear little now in photographic circles of the amateur taking the bread out of the mouth of the professional, or of expressions to that effect; and we are glad to know that peace and harmony prevail between the two bodies of workers. The amateur more often brings grist to the professional mill when he attempts to set up a rival mill on his own account, and although there may occasionally occur cases in which the professional may feel aggrieved, they are certainly not common. We must remember that in nearly every occupation the amateur element exists, and very often it treads very heavily upon the toes of the professionals. The musical amateur turns up everywhere, and as to the histrionic amateur, he, and also she, is a positive menace to the existence of the professional actor and actress. People of means are actually paying managers for the privilege of acting small parts, and the manager, finding it far more blessed to receive than to give, makes no objection to such a comfortable arrangement. He gives no heed to the claims of the far more competent professional round the corner who may perhaps be on the verge of starvation for want of a job. It is a form of heartless selfishness which prompts a man or woman of leisure to thus step into a crowded profession, to compete on such unfair terms with those who depend for their bread and butter upon finding a place "on the boards."

* * *

Who Invented Picture Postcards?

There is no question that the production of picture postcards has developed into a big industry all over the world, and the question has now arrived as to who was the first inventor of them? It was claimed for a German that he was the first, in 1872, to reproduce pictures and portraits on the back of postcards. Now it is claimed, according to the "Standard's" Paris Correspondent, that the credit is due to a Frenchman, who, in 1870, during the war, issued them as a "Souvenir of the National Defence." Be this as it may, it is only of late years that picture postcards have become popular and assumed the proportions they have as an industry. This country was perhaps the last country to catch on with the "craze." A friend tells us that when he was in Germany six years ago the shop windows were full of them, albums were sold for containing them, and they were being hawked round in all the restaurants. At the request of friends there he promised to send them some from London on his return, and he had the greatest difficulty in obtaining them, and when he did, he found that they were crude things, all "made in Germany." He would have no such difficulty now. The majority of the picture postcards now made in England, particularly the photographic one, will hold their own against those of every other country. But no matter to

whom the credit of the invention may be due, credit should also be given to those who have developed the picture post-card into the important industry which it has now become, not only in the country of its origin, whichever that may be, but throughout the world.

False Trade Descriptions in Photography.

A case of interest to some photographers—although it had no connection whatever with photography—was tried one day last week at the County of London Sessions. It was this. Two persons were tried for affixing false trade descriptions to certain wines, i.e., bottling inferior wines and labelling them as the genuine wines of well-known brands. One of them, the principal, was fined £40 and £20 costs or six months' imprisonment in the second division, and the other £10 or one month's imprisonment in the same division. The formal indictment was for conspiracy. It is the practice with not a few unscrupulous photographers to foist off on the public silver prints of the gaslight, or bromide, type as platinumotypes, although they have charged such an extra price for them as would have enabled them to supply the genuine thing at a very good profit, even much more than they would get on their ordinary silver prints. We have also heard of silver prints being supplied as carbons. This is, of course, a fraud on the public, and brings them within the False Trade Descriptions law, and renders them liable to very substantial penalties and costs, just the same as with other false trade descriptions. In the case just cited the prosecution was instituted by the firms aggrieved, and we have been somewhat surprised that the makers of platinum papers have not, before this, taken action against photographers who palm off silver prints as genuine platinum ones, both in their own interest and for the credit of the platinotype process. If silver prints which have been foisted on customers as platinotypes fade the idea will get abroad that platinum pictures are not permanent, which they unquestionably are. Unscrupulous photographers will do well to take warning.

* * *

Disposal of Negatives.

In the "Answers" column last week, we replied to a correspondent who wrote asking the best way of disposing of old negatives, presumably by sale. But the question arises has a photographer the right of selling negatives of portraits he has been paid for taking? They are undoubtedly his property. That point has been settled, both in Minor and Superior Courts, but has he the right to deal with them as he likes? Surely, some may say, anyone has a right to do as he likes with his own property, but that may not be the case with portrait negatives. It has been ruled in the Court of Chancery on more than one occasion, when injunctions were granted, that the photographer has no right to make use of a customer's negative for any purpose of his own—they were held in trust, as it were, for the customer. Therefore, has the photographer the right to sell them any more than has he the right to sell prints made from them? We should say, decidedly not. A sitter who would object to his or her portrait being sold or exhibited by the photographer who took it would certainly be still further annoyed by seeing it shown by any other photographer who might have purchased the negative from the one who took it. We sometimes see advertisements for portraits and negatives, to be used as specimens, but it is obvious from the decisions already given in the Law Courts that the sale of such is illegal—supposing, of course, that the photographer was paid for taking the picture in the first instance. This opens a very wide question because in the disposal of a business the negatives

go as a part of the good will. As the question, as have just said, is a wide one, we may have something more to say upon it on some future occasion.

* * *

Meteorology. Though we do not suggest that subject that plays so important a part in photographic plans and arrangements and their realisation, meteorological vaticinations, is, to use a common expression, going to boom, it cannot but be noted that every indication the trend of events shows that it is likely to become increasing practical value. Recently we showed that officialdom was being moved in the right direction, reports from various parts of the world show the increasing usefulness of meteorological stations. For example, Meteorological Report of the Service in Canada for 1903 was recently issued, and from its pages may be gathered results of forecasts over a large area—from Newfoundland, Bermuda. Most of the telegraphic reports go to Washington, and from there sixty-eight of them to Canada. This is thus a comprehensive series of observations of the state of the weather over a very wide range of territory for which the Canadian Office compiles forecasts for all parts of the Dominion lying east of the Rockies. A series of percentages of success is given, and from them we observe that 86.6 per cent. were successful. Storm warnings, which, however, perhaps, cannot be considered germane to photography, were 88 per cent. fully, and 95 per cent. partially, successful. Then, again, the results for the same period from the Perth Observatory and other places in Australia are to hand. The newspaper is catered for by morning and evening reports, made specially for the purpose, being issued with great success. Complete failure is most rare occurrence. The Government Astronomer (W. E. Cooke) states that the predictions of rainfall for the interior, given several days in advance, were entirely successful, and that the experiment indicates a forward step in practical meteorology.

Photography in September.

Autumn is now with us, and some of us may be thinking of relinquishing outdoor photography very soon. But why should they? This is perhaps the best time of the year for landscape work, and the foliage is still at its full, though generally changed in colour. The cast shadows are longer and more transparent than they are in the summer, while they are short and heavy, while the light is still good and fairly actinic. Indeed, autumn is considered by many the leading landscape workers the best time in the whole year. The majority of the best pictures (12 by 10 and 15 by 12) of the late Mr. Vernon Heath, both by the plate process and with gelatine plates, were taken in early autumn, and his work still requires beating, although orthochromatic photography was not then in vogue. With autumnal tints on the foliage orthochromatic plates, with a pale colour screen, is a decided power at command, and they will prove a great advantage. About the time of the autumnal equinox there is generally fine cloud effects about, and these with orthochromatic plates and a colour screen can usually be obtained in the landscape negative. This is also an excellent time for securing a stock of cloud negatives for printing into pictures taken in the summer when there were no clouds about. Stale plates that one would not care to use for other work may be utilized for the purpose, so that old plates may be turned to good account instead of being wasted. Many cloud negatives it may be mentioned, are spoilt through the camera being pointed too much to the zenith, so that they do not accord with the lighting of landscape. In taking cloud negatives the camera should be directed more to the horizon,

would be in taking a landscape. With "cloud studies" the case is different, then the camera can be pointed to the clouds in whatever direction they may be.

* * *

Photography. London is, at the moment, again in the throes of one of her periodic upheavals, on all sides evidences of the British navy and his methods are to be observed. From the photographers' point of view, however, the present chaotic state of some of the leading thoroughfares, owing to the delving of the aforesaid navy and his companions, and the consequent congestion of vehicular traffic, adds a picturesque touch to the streets, of which possessors of hand cameras would take full advantage. The recurrent groups of way men manipulating seething cauldrons of fluid cooking pitch, while others tear up or relay the wooden blocks that constitute the roadway, are subjects worthy the most skilful treatment, while the grouping to be observed during the laying of electric cables is always of great consideration. The attention of the camera user is only to be drawn to the striking effects observable in him to make the utmost of the opportunities that present themselves. The procedure is, in most instances, no more difficult than that of ordinary street snap-shot work, while the results will undoubtedly be infinitely more interesting, and amply repay the expenditure of time, plates, and money. The same sort of thing occurs at intervals in nearly every provincial town and city, although London appears to hold her own in the matter, and it may be interesting to those who think from the aspect of some of our busiest streets at the present moment that London has never finished rebuilding since the Great Fire, that the royal proclamation ordering this to be done was dated September 13, 1666, and that, we are told by a chronicler of the time, "to the astonishment of all Europe, and by the vigilant vigilance of all parties concerned, London was rebuilt in the short space of four years." It will be to the astonishment of all Europe, judging from the criticisms of our foreign visitors, if in four years more the various cities concerned will have ceased tearing up the streets, whenever one or another of them wants to put a tube or a pipe of some sort underground. Our readers can therefore in the meantime console themselves with the reflection that admirable material is being supplied on all sides for a species of snap-shot to be found in probably no other city in the world with such prodigality.

* * *

Photography. It is almost a truism that men who do the best work, either in photography or any other branch of intellectual labour, are content with simple apparatus. Some of the most remarkable discoveries in science have been actually worked out with the aid of cigar boxes, glass tubes, sealing-wax, and the like. Indeed, the early workers had to be self-dependent for their apparatus, for the optician as we know him to-day, the clever artificer, who can compass anything from mere verbal description, had not yet been evolved. Even such comparatively recent experimentalists as Professor Helmholtz was content to design his own apparatus, and we well remember that when he gave his memorable demonstration of the powers of the microphone, the odds and ends on his table, consisted of fragments of carbon and coils of wire, the intrinsic value of which was nil. Microscopists have long been divided into two distinct classes of men. The dilettante, or "brass and glass" gentlemen, and the more earnest workers who have earned the somewhat vulgar, but in reality complimentary, sobriquet of "bug and slug" men. It is a great comfort to the ex-

perimentor to have first-class apparatus ready to his hand, and he does not always get it. At the same time we all know that its possession does not guarantee success; the right description of brain must be behind it. The Sultan of Morocco some time ago ordered from a London dealer a most elaborate photographic outfit, in which mahogany was superseded by the noble metals, but we have not yet heard that any extraordinary things have been achieved with that gorgeously-adorned camera. And we may suppose that we shall be hearing of similar extravagant outlay in apparatus before those remarkable sales at Anglesey Castle shall have been numbered with the past. For we may be quite sure that the noble owner must have included photography in his wide list of accomplishments. When we read of a leather dog-collar, set with turquoise, amethysts, carbuncles, pearls, and other trifles, we can imagine how much could be done with the wider area presented by the leather bellows of a camera. With such bellows jewelled, and with lenses mounted in 18-carat gold, even a marquis might be contented. And then there is the tripod stand. If simple walking-sticks can afford opportunities for the jewellers' skill, how much more should the tripartite support for the camera arouse his artistic enthusiasm. Then the tripod head might be made of Lapis lazuli, mother-of-pearl, ambergris, radium, or something else extremely costly. Really there is no end to the possibilities before the individual of photographic tastes with abundant means, who aspires to be "soon parted" with his money.

* * *

Radium Everywhere.

By means of a new form of electroscope, a modification of the instrument called after Exner, the main features of which are the separation of the aluminium leaves by means of amber, and the production, by the use of metallic sodium, of a dry atmosphere, Messrs. Elster and Geitel have been measuring the radio-activity of soils, and the mud of thermal springs. Taking, for example, the hot springs of Batuglix, they were able to show that its activity was due solely to the presence of radium. In a recent number of "Terrestrial Magnetism and Atmospheric Electricity," they put forward the view that the conductivity of the atmosphere is largely, if not entirely, due to a radio-active emanation proceeding from the earth's crust, their argument being that the electric conductivity of air in closed cellars and in deep holes or walls is sometimes fifty times as great as in normal air. They also endeavour to prove that when the atmospheric pressure is low there is a tendency for the emanation to escape from the earth's crust, it being a fact of observation that the conductivity of air is greatest during low barometric readings. The possible photographic bearing of these observations is highly interesting. Thus, for many years we used to hear of the occasional bad qualities of certain plates out of batches of one or other excellent brands, and, though we hear less of the matter now, the complaint does crop up from even experienced workers. The cause is most probably some undiscovered fault of working by the complainer, leaving aside the bearing of the old saw of "a bad workman," etc. The point we would make is the possibility that there may be a hitherto unknown factor to be considered, and that to radium emanations, brought about as above described, the defective results referred to may be attributed. Lest this should be considered as a mere fanciful idea, we will narrate a special experience lately submitted to us by a well-known contributor. The penetrability of many solid and optically opaque bodies by the Röntgen rays is well-known, but some of its bearings are liable to be lost sight of in practice. In the case we refer to there was a general condition of frequent fog, more or less modified,

without apparent cause. No experiment could reveal any cause for some of the plates out of a particular batch developing with fog, while their predecessors were perfect. But the defect was frequent, and always visible upon the finished negatives. We were personally appealed to in the matter, and were eventually enabled to give the probable cause of the mysterious trouble. The owner was in possession of a large Ruhmkorf's coil, which he used for producing the Röntgen rays, and when working it the coil and the tube were kept on one side of a wall behind which were the stock of plates. It was quite evident that the rays from the vacuum tube, when in action for some time, penetrated the wall and acted upon the plates.

* * *

Photographs of the Pleiades. That beautiful little cluster of stars which has always been an object of interest to the star-gazers—it is mentioned in the Book of Job—has often been photographed, and, as might be expected, the photographs show much more than any visual picture can afford. Any person possessing average eyesight will pick out six or seven stars as constituting the cluster. A good opera-glass will detect about one hundred, while a telescope will reveal several hundred separate orbs. Twenty years ago, the brothers Henry, of Paris, as well as the late Dr. Roberts in this country, secured photographs of the Pleiades which showed that the principal stars composing the group were surrounded by wisps of nebulous matter, and in 1893 Barnard, using a large portrait lens and giving an increased exposure, proved that this nebulousity was of enormous extent and completely enveloped the principal stars of the cluster. More recently, Mr. G. W. Ritchey, who holds the post of assistant professor of practical astronomy at the Yerkes Observatory, has, by means of the two-foot reflector belonging to that institution, succeeded in obtaining an image of the group of stars which shows minute details of structure of the nebulous masses. This picture, with photographs of other stars, he has utilised as an illustration to an article on "Photographing the Star-Clusters," which appears in the current issue of "Harper's Magazine."

There is one feature in this remarkable photograph which appears to be unique, at least it presents something different from anything found elsewhere in the heavens. The dark background upon which the stars are spangled is intersected by a number of nearly straight and parallel streaks of luminous matter. It is assumed without question that these lines are part and parcel of the Pleiades system, and we may suppose that they have been detected in different photographs so as to obtain corroborated proof of their reality. We assume this, for it is easy to see how such streaks could be produced by accidental light access to the plate during such a prolonged exposure, and it would be by no means conclusive if the same appearance were exhibited by different photographs taken with the same instrument and under the same conditions. Mr. Ritchey states that extremely sharp negatives of the Pleiades have only been obtainable during the past five or six years, and that such pictures have been taken with reflecting telescopes of such comparatively small focal length that the scale of the resulting pictures has been small. He considers that when a really big reflector is constructed for the work, and employed systematically for a term of years in a fine climate, a great addition to knowledge concerning these mysterious objects will be gained, and that much may be learnt about the development of nebulae and stars generally. But there is one remarkable feature of the photograph of the Pleiades reproduced in the article, to which he does not call attention, and probably for the very good reason that it was not in the original picture, which of course he would have before him as he wrote the article. The principal stars

of the cluster are each surrounded by so much nebulous matter that they have the appearance of street lamps in a fog, and, apparently, in order to give pictorial effect to them, someone, in preparing the picture for the block-maker, has added radiating lines of light, like the spokes of a wheel, to each orb. This would perhaps be justifiable if the pictures represented a display of fireworks, but to touch up in this way a representation of the starry firmament is quite inexcusable, and is akin to pencilling details into a photomicrograph. Many pictures are improved by skilful use of the brush and pen before they go to the blockmaker, but a photograph of any natural phenomenon in which interest centres upon points of structural detail should be left severely alone. The proprietors of "Harper's Magazine" are generally so jealous of the excellence of their illustrations that it is a matter for wonder that the "retouching" of this star picture should have eluded their vigilant eye. The author of the article would certainly be one of the first to protest against it.

REVIVAL OF THE OPTICAL LANTERN.

THERE are indications that the optical lantern is likely once more to make its way into prominent popular esteem as a means of entertainment, amusement, and instruction, a position from which it was ousted a few years ago by the cinematograph. It is no secret that the optical lantern trade has for a long time reflected public taste, or the lack of it, in this respect. The sale of lanterns, in short, experienced an unmistakable slump before the advance of the omnipresent animated photograph. But is the latter in possession of such a degree of favour as it enjoyed, let us say, two or three years ago? It is hard to reply with any definite approach to absolute accuracy, although in our opinion the evidence points to a negative conclusion. For, wherever the seal of vulgarisation attaches itself to any popular craze it may safely be expected that the neglect of the better or cultivated classes unfailingly follows. How long, then, may it be asked, will the animated photograph boast its present supremacy as a manifestation of lenticular agency in the representation of life and movement, in view of its falling into the groove of filling a turn at a theatre of varieties or a travelling fair temporarily located in a country hamlet?

We are, of course, no enemy to the animated photograph, let it be shown wherever you will. To-day the fascination of the movement as illustrated on the screen is as great to us as it was nearly ten years ago, when Messrs. Lumière startled the West End of London and ourselves with the results of their early experiments in cinematography. But we confess to a feeling of regret that it should so long have eclipsed the immobile lantern transparency in general esteem. There are properties in this kind of photograph which have been perhaps overlooked whilst the pendulum has been swinging so far over towards movement on the screen, with its concomitant drawbacks and defects. You can examine and study the still image at leisure; and the fact that it was not necessarily produced against time, in either its negative or positive form, admits of the introduction of purely technical beauties rarely possible in long strips of tiny pictures blended by mechanical and retinal agency into one large view. True it is that the animated photograph tells its own story, but your lantern-slide gives the lecturer an opening, and it is precisely because this essentially human element is mostly absent from cinematograph displays that we think the lantern lecture stands just now a very good chance of revival, with consequent benefits to the lantern industry. Indeed, we hear from various sources that lantern manufacturers are anticipating a return to the prosperous times of former days when the

sale of instruments was more satisfactory than it has recently been.

The American worker, Mr. Burton Holmes, whose travelogue lectures in the early part of the year greatly attracted London pleasure-seekers, met with such success that we are justified in assuming the public is quite ready to receive more of the same sort of thing. Mr. Holmes gave a mixed cinematograph and lantern entertainment; but he was a facile lecturer, and his pictures were so good that in all probability his audiences would have been quite contented with single photographs singly shown. Good lecturers are, however, scarce, a fact which may, in some measure, account for the comparative desuetude of high-class optical lantern entertainments. The example of Mr. Burton Holmes may not, it is to be trusted, be lost upon capable exponents of this undoubted art. Nothing is more painful to one than to have to sit out a display of good transparencies accompanied by the monosyllabic ambiguities of an indifferent talker at the lecture desk. A happy combination of good oratory and good photography never fails to secure public applause.

We would therefore put it that the time is ripe for a revival of interest in the optical lantern. Our thoughts are not now occupied with its use in the somewhat restricted field of photographic society endeavour, but rather with the larger and greater world beyond it.

There is no question at all that a paying public exists for good entertainments of which lantern transparencies form the bases. But subject and subject-matter must be of irreproachable excellence. The half-educated globe trotter with his collection of streaky and spotty slides from incorrectly exposed and developed negatives has done much to kill public interest in optical lantern entertainments. These people should not be permitted to adorn the platform any longer. The success of the cinematograph is due to the fact that it arouses the interest and holds the attention of the audiences gathered together to contemplate the results on the screen. The cinematograph has admittedly passed into its ultimate sphere of being a companion of, or supplement to, the newspapers, best studied after dinner at variety theatres. In that respect this branch of photography admirably serves its purpose. But there is an enormous public which seeks its relaxation, and to some extent its instruction, in the town hall, the lecture room, and the "lit. and phil." Is it not worth the while of competent lantern lecturers to cultivate that public? We should not look to this cause directly to resuscitate interest in the optical lantern; but it would undoubtedly do so indirectly, for it might reasonably be trusted to stimulate those persons who have recently neglected this system of projection to once more add it to their home diversions. Aside of all these considerations, we are convinced that a good time is once more in store for the lantern trade—for the dissemination and popularity of the instrument *per se*—and we believe that makers will be well advised, now that the cinematograph has found its final place, to make efforts to popularise optical projection apparatus amongst amateur workers all over the country. In a season or two we shall expect to hear fewer complaints on this score than those to which we have recently been habituated.

"THE STUDIO" will shortly publish a Special Autumn Number devoted to the work of two of France's greatest humorous draughtsmen—Daumier and Gavarni. "The Studio's" special will contain, as usual, a large number of coloured plates and photogravures, as well as full-page facsimile illustrations in black and white.

A SIMPLIFICATION OF THE GUM PROCESS.

WHILST I have not the slightest faith in the future of bi-gum as a printing process, except for those who wish to veil in murky mud their incomplete technique and want of knowledge of the main principles of art, and appeal to the love of the eccentric, the following modification may be of some interest, as it certainly presents some elements of novelty and some advantages, in that the gum worker can prepare any number of sheets beforehand, and then pigment them with any desired colour. The novelty lies in the application of the chromate first, then drying, and the subsequent application of the pigment.

The process is described by Herr Renger-Patzsch in a recently published work entitled "Der Eiweiss-Gummidruck."

A stock solution is first prepared as follows:—

Distilled water	100 cc.
Ammonia bichromate	15 g.
Manganese sulphate	8 g.
Boric acid	3 g.

This will keep, and to every 15 cc. of it before immediate use is added—

Absolute alcohol	2.0 cc.
Formaldehyde	0.5 cc.
Fish glue (clarified)	2.0 cc.

The mixture will not keep well; it should be thoroughly mixed and applied to the paper with a brush as evenly as possible, and then thoroughly dried, and in this state it will keep in the dark some time.

The pigment solution is prepared either with dry powder colours, or tempora, or water colours in tubes, the quantity of pigment varying of course according to the form of colour used, and whether one or more printings are resorted to. The following solutions are also required:—

1.—Egg albumen.	
2.—Gum arabic	50 g.
Water	100 cc.
3.—Metol	0.2 g.
Glacial acetic acid	3 drops.
Water	100 cc.

The actual pigmenting solution is composed of—

Pigment	0.5 3 g.
Albumen	12 cc.
Gum solution	5 cc.
Metol solution	12 cc.

This mixture is applied with a brush to the previously chromated paper and evened out with a soft brush and dried.

The exposure for paper thus prepared is said to be very short; for instance, under a thin negative in the sun in April it is stated to be less than a minute, but equally good results are obtained by exposing in diffused light, unless a very large amount of pigment is used, when sunlight is preferable.

Development may be effected in any of the usual ways, though it is strongly recommended to place the print face up in a dish and flood with water, the mechanical attrition of the water being usually enough, but a fine water spray may be directed on to parts of the print whilst still lying under the surface of the water, the thin layer of water breaking the force of the spray. Sawdust soup or brushes may also be used.

E. J. WALL.

A SUMPTUOUSLY printed brochure is the latest thing in catalogues from the firm of Newman and Guardia, Ltd., Shaftesbury Avenue, W. It dilates upon the many admirable qualities of the N. and G. Reflex Cameras, and points its remarks with beautifully printed half-tone illustrations showing in a practical manner what can be undertaken and what can be achieved with these splendid instruments. Every photographer should obtain a copy of this catalogue.

NOTES BY THE AMATEUR OPTICIAN.

I HAVE during the past three weeks felt the want of something new in the way of dishes. The small sketch herewith shows a design which I commend to makers in the firm and confident belief that it will meet a long-felt want. I required to do some developing away from the usual dark room, and the conveyance of solutions, dishes, etc., became a weariness to the flesh. It was necessary to develop and fix and transfer to a dish of clean water a whole-plate negative, for conveyance afterwards to the usual washing arrangement. There was not much space at command, and the ordinary dishes measuring 9 by 7 and 10 by 8, and so on, took up a lot of room and only carried one negative at a time. To secure the desired relief a wood tray was made to hold two negatives, one of which was placed upon the bottom of same and the other about half an inch above the first, resting upon two ledges fixed in the tray, and running parallel, of course, to the sides of the bottom negative. If a dish be made square—and a square dish would be just as useful as one of oblong shape—it is obvious that with the provision of a ledge of half an inch or so width, there is plenty of room for two plates in the dish placed as in the sketch, whereby there is a great economy of space.

The wooden tray referred to answers the purpose, but I should be glad to make a purchase of two or three porcelain dishes of similar design.

Many readers will have remarked a note which recently appeared in the Press with reference to the Wireless Telegraphy Act. The editor of the "Model Engineer" wrote to the Secretary G.P.O. to ascertain how the new Act would affect people who are using wireless telegraphy apparatus for experimental purposes and for private use. The reply received indicates that an official licence is requisite practically in every case, and that each application will be considered on its merits." For my part, I made application at once, and am now—waiting results. I shall be surprised if many licences are granted, whatever may be done at present and for a year or so. One is able to get strange and marvellous results with only a very small and insignificant coil, and even putting on one side a piece of mechanism for purely telegraphic purposes, what about the use experimentally of a Hertz oscillator? This is by no means an "Oliver Lodge" transmitter, and still it acts similarly upon a coherer. I have illustrated and tested this on numerous occasions, and can easily understand that a few of these working here and there might seriously interfere with official apparatus.

THE hon. secretary of the Darwen Photographic Association announces that the second annual exhibition will be held on November 17, 18, and 19, with Messrs. Percy Lund and C. F. Inston as judges.

A PHOTOGRAPHER AT THE SEAT OF WAR.

THE Holiday Number of "Collier's Weekly" is a most interesting production. It is a matter of common knowledge that Robert L. D. who was specially sent out by the proprietors as photographer, the only correspondent in time to get through before the closing of Port of Korea by the Japanese. As a matter of fact, he was established at Chemulpo before the Japanese arrived, and, to quote his own words:—

The war had not begun. There was evidence on every hand it would start shortly. The harbour of Chemulpo was studded with war ships, nearly every nation being represented. The port closed. The mails stopped. The wires became silent. Tidings from the side world were not to be had. The air was feverish with suppressed excitement.

On the momentous night of February 8, the Japanese transports landed their first 3,000 soldiers on the bund of Chemulpo. The excitement was intense. In my ulster I carried a magnesium flash lamp. Upon my shoulder was carelessly strapped my Kodak. When the excitement was at its height, and the soldiers in absolute silence were lighting the huge log fires, a cry went up, "The Russians!" The cry came from the Koreans, who had packed the wharf to watch the landing. They had seen the flash of my light as I hurriedly made a picture of the scene.

After making flash after flash of this most remarkable midnight landing, I hurried to my quarters in the filthy Chinese hotel, and there with my developing machine spent the rest of the night in turning out what proved to be the most successful lot of flashlight films soldiers landing ever taken.

The next day I hurried by first train to Seoul. Seoul presented many scenes picturesque—the arriving soldiers, the school children massed into line to meet them, and the heavily laden bulls carrying towering loads of supplies for the army corps.

It was just at the stroke of twelve that a dull boom sounded, miles away; another and another, and yet another. The war had begun. The first battle was on at Chemulpo, twenty odd miles back. The war I had come to see had started, and I was not at the starting line. Hurrying into a jinrikisha I shouted to the "Kurumaya," "Five yen if you get me to the station in ten minutes." The coolie did not understand the language, but he comprehended the "five yen" and flashed in his face. He called two men, and the three went through the streets as though mad. They certainly earned their money. There was no train. Afar off the cannonading sounded, louder and louder. My Kurumayas were tired. Leaving them, I started on the long journey with one big, strapping coolie. Inside of a block I had gathered seven others to assist. This crowd of eight hurrying fleeing coolies excited the town. On and on and on we went over frozen rivers, through heavy ice-crusts, rice fields, and, worst of all, the great sand plains. I rode, then I walked, then I ran.

Arriving at Chemulpo I hurried to the water's edge. Sampanns were plentiful, but no sampanians. The Koreans had taken to the hills, and it required the liberal use of "gilt" and a club to get one. I got four and through the choppy rough sea I hurried out to the U.S.S. "Vicksburg."

From the "Vicksburg" many scenes were to be had. The "Korietz" the "Sungui," and the "Varing" of the Russian fleet, and warships of nearly all nations. The "Varing," powerful as she was when I photographed her the day before, now rolled with every wave of the in-coming tide. Her funnels were perforated, her decks strewn with wreckage, her guns twisted, and almost completely dismantled. While I was making picture after picture a flickering light appeared on the "Varing." From this light and from the curls of smoke flamed a huge torch. The cruiser was afire. The fire seemed to have broken out in the exact spot where the hurriedly fleeing sailors had placed their forty-two dead. With these bodies cremating, the ship burned, and at 5.30 she was seen to totter and list heavily to starboard. As she listed the flames rose higher and higher. At six her decks touched the water, then her funnels, and, with one loud, deafening sound, she sank.

The onslaught of the Japanese upon the little Russian fleet was sudden, terrific, overwhelming. It could have but one result, and when the smoke of battle had cleared away and the great guns were once more silent, the smoke stack of the sunken "Korietz" marked her burial spot, standing like a monument upon the field of battle to

mark the first epoch in the struggle between the Japanese and the Russian for supremacy in the Far East.

With my Kodaks never so full of valuable films I worked all night developing. I had over 100 exposures. They represented one of the most valuable collections of war scenes ever photographed.

After the battle of Chemulpo the first detachment of Japanese soldiers headed for Ping Yang, the former capital of Korea. With my cameras, films, developing machine, and provisions carefully arranged on pack ponies, I started with the first troops for the North. For days I travelled with this overland draft of soldiers. I won't say with them, for I didn't. They occupied the roads, and I hobbled across the frozen fields.

There never was a time when good photographic scenes failed to present themselves. At every turn of the Kodak key I could make an interesting exposure. There were the tired, weary, footsore soldiers trudging along the icy roads, the lame, overworked horses dragging a towering load of army supplies. Exposing a film was easy, but developing and finishing in the open field was another problem. In fact, it was one of the hardest, most trying problems I had. First of all, the thermometer was always hovering around zero mark. The next problem was water. Cleanliness and water are foreign to the Korean nature. One well to a village is the rule, and water in plenty one must have when there are dozens of films to be developed.

And so each afternoon found me driving ahead at full speed to secure, if possible, one small Korean room for myself, horses, and entire army of helpers. The moment I entered the village and was able to secure any sort of a filthy room, the entire population was sent scurrying to the town's only well for water.

The primitive method by which I obtained my water supply is well illustrated by the picture of a Korean girl with a big jar of water on her head. It would tax a man to lift such a weight to his shoulder, yet this mere child, inured to hardship, carried it without difficulty. Indeed, the opportunity to earn a little money was so attractive to her that she followed our little party from place to place for what she could get in this way. Sometimes she could keep pace with us, and for a few days we would not see her; then she would again appear on the scene, ready to help in the carrying of water for my developing machine. By the time my helpers with the packs arrived, water in every conceivable pot and pan in town was in readiness for the developing.

After carefully fastening the gum end of the film I started on the process of developing. To say it was an anxious process does not half explain the trying moments I watched and waited to see if the changing temperature of the water should make my work a failure. A single failure would have meant the loss of a film never to be replaced. One can easily imagine the value I placed on each film, or, in fact, each developing powder when they understand I was the only photographer in Korea with a very limited supply of material, and did not know how soon the port would open. I was getting exclusive scenes daily, making pictures against the wishes of the Japanese Government, and each picture showed the progress of a nation going to war.

For a strong personal reason I cannot but praise the Japanese for closing the port of Korea when they did. Had the port remained open only a few hours longer, I certainly would have had company in the picture line. As it was, I remained absolutely alone for over two months as the only war photographer in Korea.

While crossing a mountain a pack pony carrying my precious developing outfit disappeared over the side of the cliffs. Hurrying to the top I perceived him turn over and over until he finally touched bottom—that is, what was left of him. Cautiously descending the slippery wall of ice, I found piece after piece of his hide, in fact, pieces enough to make a fair sized crazy quilt. At the bottom my scattered pack and badly crushed case of powders were located. The boy had secretly hidden a bottle of whisky in the box of powders, and for a moment I thought the whisky-soaked wrappers would prevent any further picture taking; but Fate was with me. Thanks to the care of the Kodak people the oiled wrappers saved the chemicals.

Then there was the worry of getting the photographs out of Korea. To have put all of them in the post office would have been like burning them up. Each and every film, to assure its arrival here, had to be posted at Chee Foo, China. Sunan, one of the most northern points in Korea, is the place from which I had to send films overland to

Chemulpo, from Chemulpo by junk, or small sailing craft, to China. Sunan is over two hundred and fifty miles from Chemulpo, the route is overland, mountainous and very dangerous. I sent a messenger almost daily for over a month. These messengers were Korean coolies, generally the ones who had worked for the missionaries, and could be fairly well trusted. It took a coolie, travelling very hard, on foot, about six days and half the nights, to arrive at Seoul. At Seoul arrangements were made with foreigners to see that the films and correspondence got the first available craft for China. Many of the runners were badly treated by the Japanese. They would get perhaps half the way when the soldiers would see them crossing a mountain. These soldiers, as I have said, were tired, footsore, and weary, simply marching along like sheep. They would take the messenger and turn him back to carry their kit; if he refused he was cuffed and beaten. Some messengers were turned back so frequently that they more than covered the distance three times, and took about three weeks to arrive. Some were turned back so often they never did finish the trip. These soldiers paid nothing for the service of the messengers, not even giving them a bite to eat.

With all that has been said against the Koreans not working, lying, and stealing, there is still one good trait in them—they are not deceitful. I tried dozens of Japanese and dozens of Koreans, side by side, and if I did not want to be deceived I never trusted the Japanese as far as I could see him. I had two Korean boys with me; they proved exceptionally smart and bright. It took only two or three days before they were able to run the developing machine, and, in fact, mix all the chemicals for developing. They learned to dry the films, clean the developing machine, and very often would take a Kodak and make a fairly good photograph. Not being desirous of getting credentials from the Japanese Government at Tokio, whereby I would be dictated to, I hustled into Korea before war was declared. With the declaration of neutrality by Korea I was then absolutely out of the jurisdiction of the Japanese forces. This does not mean, however, that they made no attempt to interfere with me. To the contrary, on several occasions they made it rather warm. This even went so far as arrest and imprisonment. Being stopped and detained for hours at a time got so common that shortly I quit protesting.

At Chemulpo, shortly after the first landing, I was stopped, searched, and cross-examined for at least an hour, and, with the familiar phrase, "I am very sorry for you," was permitted to depart. The Kodak dangling from my shoulder was always to a Japanese soldier what a red rag is to a bull. They pretended not to notice the Kodak when they stopped me; however, their awkward searching process led them to ask me what it was and to request to see it. They knew a Kodak as well as I; they simply wanted to see it opened, hoping thereby to ruin a film.

Had not the Fourteenth Regiment, on its arrival opposite Ping Yang, been such a thoroughly tired, frozen, and worn-out lot, I never would have been able to remain among them long enough to get a picture. The moment I suddenly appeared on the hill several started for me, explaining, "Very, very sorry," but their feet were so badly frozen I had finished and was ready to depart before they got near enough to tell me I could not make any pictures. After the regular process of questioning and searching I was taken to the Captain, re-questioned, re-searched, and detained for hours. During this time I was held on the ice while they kept the wires of the field telephone hot between Ping Yang and Seoul. They talked, questioned me, re-talked, re-questioned, and talked again, only to find they could not hold me, and with the same refrain I had heard so often, "Very, very sorry," told me I could depart.

The picture of the troops at rest tells of the miserable condition the men were in. Nearly every soldier was frost-bitten, yet all were so exhausted that they threw themselves upon the snow, and, with dogged patience, awaited the order to march across the river into Ping Yang. As a partial protection from the biting wind, a trench was dug in the snow along the side of the road, and here the poor fellows remained for hours together, ready to march on or to be taken to the field hospital for the amputation of either toes or feet.

To turn back is something of which the Japanese soldier knows nothing. The picture of the "Footsore Stragglers in the Rear of the Japanese Army" tells the story. They may be treacherous, dishonourable, falsely polite, but every inch of the five feet in height that goes to make up the Japanese soldier is pure pluck. The stragglers which my Kodak shows going down the mountain side should have every

one been in hospital. But to be wounded or sick, that is a disgrace. Death or a victorious return to the island home—these are the only desirable ends to the struggle possible from the Japanese standpoint. All these stragglers knew was to plod along until tired Nature refused to take them further, then to sink down in the snow for an hour or so of sleep, and at the first awakening, on again in the painful struggle to come up with the main body of the army miles ahead.

The excitement among the Koreans as they hurriedly crowded the top of the historic gates of Ping Yang to watch the arrival of the first Japanese soldiers was certainly intense. They huddled together like sheep in a storm. They were frightened, badly frightened; in fact, too frightened to clear the entrance when the soldiers started through the gates. They were clubbed with the butts of guns, and viciously treated by the soldiers, who hurried into the town.

Naturally, the development of films had to be done in some out of the way place. A hut, if possible, was located at the extreme side of a village, where the soldiers could not interfere without going far out of their way. With the aid of Korean boys I worked hour after hour in the cold to develop my work, that I might be able to renew my tedious journey. The water had to be warmed, so had the machine, and by working rapidly we were able to develop the roll before the developer would get too cold. Frequently, after development had ceased, the developer would freeze before we could pour it off and add the fixing. Constant movement of the films in the final wash had to be carefully watched lest the water should freeze solidly about them. Frequently my fingers became so numb I could not handle the films long enough to hang them up to dry, making double work every time I dropped one by having to re-wash it.

Sometimes I was more fortunate, and would find time to do my developing during the day, and no dark room being necessary with the machine, it was a comfort to be able to operate in the open air instead of in the filthy, vermin-infested, huts of the natives. With a Korean boy to turn the crank of the machine I was at liberty to attend to the mixing of my chemicals and to the washing and drying of the films.

And speaking of the chemicals, I actually cornered the photographic market in Korea. Realising soon after my arrival there that I was the only correspondent actually "at the front," and that practically the only other photographic apparatus in the country was in the hands of the missionaries, I desired to make certain of a "scoop" for my paper by making the other cameras useless. To this end I bought all the photographic supplies in sight, whether I could use them with my apparatus or not. Of course, I could make most of them of value in some way. At one place I obtained a supply of "Brownie" developing machine powders. One of them would not make solution enough for my 5in. by 7in. machine, but it did not take many seconds to figure out that five of them would make up the forty ounces of developer required. Of one missionary I might buy a little pyro, somewhere else I would get hold of a few pounds of hypo. It was not long before I controlled the photographic situation, and had thus doubled many times the value of the pictures I was taking, to say nothing of having added materially to the stock so necessary for my own work.

With my Kodak under my saddle and the saddle for a pillow I turned in each evening about midnight. In the small filthy room was my entire outfit; from every inch of hanging space was adjusted a drying film. I got little sleep, however, fearful lest someone should enter and destroy my most valuable collection of views. About three o'clock I had to turn out and caption each picture, then arrange for messenger service back to Seoul. Daylight found me pushing ahead of the army.

I tried usually to keep ahead of the army, for in that manner I could reach the villages and become supplied with food before the soldiers arrived. I found this necessary, in order to get enough food, for it was almost impossible to carry sufficient to supply my wants while journeying over the country with the thermometer registering below zero.

My hardest task was to get bread. Often for weeks I ate none of it at all. I struck a province full of missionaries, and I spent two days riding around among them, trying to buy what bread I could. Finally, I collected ten loaves, and, delighted with my success, packed it all on the back of one horse and went on my way. A few hours later I reached a river, in which the ice had broken and carried off the pontoon bridge. I loaded my horses and men in a sampan and started across. We were half way over when a young iceberg struck the boat, and the horse carrying the bread fell overboard, and neither the horse nor my precious loaves ever came to the surface.

With every member of the Japanese army throwing obstacles in one's way at every turn, with the Koreans stealing one's horses, the constant struggle against filth and vermin, with all food scarce and bread a luxury, with absolutely no convenience for picture making except such as can be carried on the miserable pack ponies, the life of the war correspondent in Korea is far from a happy one. With all these trials and tribulations I succeeded in sending my pictures that have been universally pronounced the best war scene ever published. Through the courtesy of "Collier's" hundreds of them have been reproduced from New York to San Francisco, and from England, Germany, and France.

THE DUNDEE WORKS OF MESSRS. VALENTINE AND SONS, DUNDEE.

THE fame of the original firm of Valentine has spread the wide world over, and the name is one which in many lands is "familiar in the mouths as household words." Mr James Valentine (writes a correspondent of the "Dundee People's Journal"), the founder of the firm, started business in Dundee between sixty and seventy years ago as a lithographer, but the exigencies of the business generally induced him to take up photography, which he did with conspicuous success and was honoured with the designation of Photographer to the Queen. Discovering in the course of an ever-increasing business that there were as great, if not greater, possibilities for the photographer in the publication of the many beauty spots of our own Scotland as in the counterfeit presentment of the faces of "its honest men and bold ladies," Mr. Valentine turned his attention to this particular branch of photography with which his name has been so long associated.

Books of local views were thus issued, and these in turn were succeeded by fancifully framed photographs, more than one of which to be usually found in the majority of our homes. As the business prospered its varied branches of light and easy work necessitated the employment of many girls, and provided an opening for them in days when suitable and profitable occupations were decidedly uncommon than in the present day. Valentine's works have been located in the Perth Road, but the introduction of the collotype machine and the ever-increasing business demanded an immediate extension of premises, so a new and up-to-date building on the west side of St. Mark's Church, and in close proximity to the original, has been recently erected, and affords employment for nearly 600 workmen. More than half of these are girls and women, so that, including those who find work in the firm's branches in London, Dublin, Edinburgh, Glasgow, York, Birmingham, Plymouth, and Manchester, there are at least 400 female employees.

The other day I was conducted all over the premises by Mr. W. Valentine, the son of the founder of the firm, and the chief manager and director of Valentine and Sons, Ltd. There was quite a number of clerks and typists in the various offices, in one of which is to be found the private post box, the contents of which are regularly collected several times a day. It goes without saying that the correspondence of such an establishment has attained very large proportions, and I understand there is only one other business in the country privileged to possess a private post office. As already indicated, the majority of the employees are girls and women, some of whom have occupied situations there for a longer number of years than they naturally might care to confess to! Their work in photography varies considerably. They are engaged in retouching, spotting, and colouring; the toning of silver prints, which are fast being ousted here; in the manufacture and colouring of lantern slides; and in the numerous other more or less intricate processes connected with the art.

Unmounted photographs are practically at a discount meantime, but the demand for framed photographs is as large as ever. The work of suitably mounting and framing these is chiefly carried on in the firm's establishment in Edinburgh. Then the books of local views require binding, and this task affords a pleasant form of employment to many of the girls, who, seated at long tables, either deftly apply the gold leaf for the titles or finish the tartan and other characteristic Scottish covers which appeal so strongly to the tourist element, particularly the Americans on a visit to "Caledonia stern and wild."

Naturally, I found most to interest me in the new Westfield Works, which are entirely given over to the preparation and publication of postcards. There they lay in piles and stacks of hundreds, thousands

and millions I should imagine—a sight calculated to make a collector break the Tenth Commandment to an unlawful degree. It would be a mistake to suppose that Valentine's series include only Scotch, English, and Irish views. They have artists and photographers engaged in every part of the globe, even in the most out-of-the-way and little-known corners thereof, who forward negatives to headquarters to be developed, printed, and evolved as the popular postcard. One order, which was being completed on the occasion of my visit, consisted of a magnificent set of hand-coloured postcards of Kimberley, South Africa, destined as the means of conveyance of kindly Christmas greetings to friends near and far. No doubt many of them will find their way back again over the waste of seas to Dundee.

The collotype machines on which the majority of the postcards are printed are mostly of English and German origin, and are marvels of mechanical skill, scientific accuracy, and artistic beauty. The process is highly intricate and rather too technical to be adequately mastered by an onlooker in the space of a few minutes, but here is a general outline of the *modus operandi*:—Large squares of thick plate glass, having bevelled edges, are chemically prepared and coated with a gelatinous substance, which, after several processes, is sensitised. The negatives of a group of postcards are finally printed thereon, the plates are then firmly wedged into the centre of the machines, enormous rollers are set a-going, and the impressions are taken with wonderful celerity. The machines are controlled by men, who are assisted by the girls in the feeding in of the paper and the throwing off of the sheets of say 18 or 20 postcards, so that the work of the latter is particularly easy and pleasant. From one machine a stream of black and white cards may be seen issuing, whilst at an adjacent machine the sheets emanate in the faintest of tones, but these are in an unfinished state, and are submitted to another machine, which cleverly touches them in with black, and they finally emerge complete, and beautiful. The edges of the sheets are trimmed and the cards separated by means of a guillotine.

One of the newest things in photography is three-colour printing, and I was shown several fine specimens thereof in a new set of postcards, depicting the engines and expresses of the different well-known railway companies. Apropos of postcards, it is rather a curious fact that Mr. James Valentine was the first to issue illustrated envelopes. These are of a topical nature, and dealt with such important movements as the abolition of slavery and the dissemination of temperance principles. Valentine's establishments are controlled by the Factory Acts, so far as the hours of daily employment, the weekly half holiday, and trades' holidays are concerned; their scale of wages compares favourably with other large employers of labour in the city, and their employees belong to the superior class of working girls. A local medical man, in his official capacity under the Factory Act, pronounces them far and away the healthiest lot he comes across—a fact accounted for, no doubt, by the hygienic surroundings of Westfield Works, and their employment, which takes many of them out into the fresh air and the sunshine, obtainable on the roof of the buildings, from the top of which the marvellously fine and extensive view of the river and the bridge is calculated to act as an inspiration to the workers.

THE NORTHERN FEDERATION AND THE AFFILIATION WITH THE R.P.S.

THERE appears to be a feeling among the members of the photographic societies of Northumberland and Durham that the Federation is antagonistic to the affiliation of photographic societies which is connected with the Royal Photographic Society. Mr. Arthur Payne, in the "Federation Record," says that this is not so, a fact well known to all those who are well acquainted with the aims and objects of the Federation, but the rapid growth of its membership naturally brings into its ranks many who are not so well informed, and it may possibly be of interest to these new members if I briefly explain the reasons for the existence of these two separate organisations. Both are equally worthy of support. Their interests are identical, and yet they do not clash. They each confer benefits and privileges to their members which cannot readily be given by only one of these two societies.

Whilst the Federation only extends over the counties of Northumberland and Durham, the area covered by the Affiliation extends

over the whole of the British Empire. They, with their vast organisation and large membership are enabled to confer benefits upon their members of such a nature that the Federation are incapable of undertaking; but the very vastness of this work prevents it possessing that element of personality which is of so much importance at the present day. And it is on that one point of "personality" that our Federation justifies, and maintains its position.

For instance, the Affiliation provide an excellent series of lectures for circulation among their members, and when these lectures are delivered by their authors they are worthy of, and attract, considerable attention, but unfortunately in the great majority of cases they must, for obvious reasons, be read by deputy, and when, as is frequently the case, the person who undertakes this task is one who has no knowledge of the subject of the lecture, and who very possibly has not had the opportunity of reading the lecture previous to the meeting, the result is, as everyone knows who had heard a lecture delivered in such a manner, chaos.

It must be admitted that when a lecture is delivered by the author, not only is it made more interesting, because it is delivered in an intelligible manner, but the fact that the audience is brought into personal contact with the lecturer is in itself beneficial to those who are fighting their way to the top, for strange though it may sound, there is undoubtedly some mysterious, or mesmeric, influence (whichever you may be pleased to term it) induced by contact with a notability, which in some inexplicable manner not only excites in the beginner a desire to do only the best work, but also enables him to understand the principles, and really appears to help him to do it in a thorough manner.

I feel sure that it is this element of "personality" which is conducive to the prosperity of the Yorkshire Union. The Affiliation also offers the use of a Board of Judges, who are prepared to judge the affiliated societies' exhibitions, but the distance of our district from the Metropolis naturally debars their usefulness in this part of England. Though the Affiliation, so far as we are concerned, fails to satisfy upon these points, there are still many advantages they offer to their members, which are well worth the nominal subscription of one guinea per year, charged to each society, and which are equally valuable to photographers all the world over.

Among the benefits conferred on members of an affiliated society that which stands out most prominently is the Red Book, a copy of which is issued annually to each. This book, besides serving as a permit to photograph in several cathedrals, parks, and open spaces, is also useful as an introduction should you meet with photographers, or desire to use a dark room, when away from home. They have also a valuable collection of fifty-four pictorial photographs by leading workers, which are available for circulation amongst the affiliated societies. The opportunity of viewing these pictures is in itself equal to a visit to a London exhibition, and, as they are framed and glazed with celluloid, they are an acquisition to any provincial photographic exhibition.

In conclusion, I would ask all the members of our societies to seriously consider the advisability of joining in with the affiliated societies in their good work of encouraging photographic progress and improving the status of photographers generally. Not only do you receive many benefits in return for your support, but the moral force of your sympathy contributes in no small degree towards the attainment of their ideals.

Societies affiliated with the R.P.S. are entitled to the following benefits and privileges:—The loan of illustrated lectures on photographic and kindred topics, sets of lantern slides, lantern lectures, pictures for exhibition, etc. Permission to photograph in the places specified above upon production of the Photographic Red Book, without special application to the various authorities. Two copies of each issue of the "Photographic Journal," in which are published the proceedings of the Affiliation Committee and the transactions of the Royal Photographic Society of Great Britain. Reduced rates for wall space and admission at the annual exhibition of the Royal Photographic Society of Great Britain. Members of affiliated societies joining the Royal Photographic Society of Great Britain receive exemption from the payment of entrance fee provided they have been for at least two years members of an affiliated society. The secretaries and delegates of affiliated societies are empowered to propose and second the nominations of such candidates. The services of a Board of Judges in respect of small society competi-

tions. Temporary use of the accommodation provided by the various societies to members away from their own districts.

Every affiliated society has a voice in the management of the Affiliation through the two delegates which each is entitled to appoint. The general body of delegates meets at least twice a year, the business in the meantime being conducted by an executive committee appointed under the provisions of Rule 6. The two delegates appointed by each society need not necessarily be members of the society they represent. The Royal Photographic Society of Great Britain reserves one-third of the amount of the subscriptions for secretarial, clerical, and incidental working expenses. The Affiliation Committee have the remaining two-thirds entirely at their disposal.

THE LATE JAMES ALEXANDER FORREST.

THE death of Mr. James Alexander Forrest, which took place on Friday, September 9, in his ninetieth year, removes perhaps the oldest link between the past and present of English photography. Exactly three months ago, in the Jubilee number of the JOURNAL we

The late James Alexander Forrest, one of the Editing Committee of the "Liverpool Photographic Journal, 1854-1856," died September 9, 1904, aged 90.

gave a brief account of Mr. Forrest's connection with the "Liverpool Photographic Journal" and general photographic affairs in the great city on the Mersey. It is with deep regret that the duty of chronicling his decease should so soon have followed upon the pleasure we felt at knowing that he was alive to witness the completion of fifty years' existence of the JOURNAL he was partly instrumental in founding. The respect in which he was held in Liverpool is evidenced by the following extract from the "Liverpool Mercury" of Saturday last:—"Mr. Forrest was at one time a member of the Liverpool Town Council, representing Lime Street Ward for several years in the Conservative interest. He was first elected to the Council in 1873, succeeding Mr. H. Hornby, deceased. In the following year Mr. Forrest was returned without a contest, but three years later he was opposed by Mr. C. J. Crosfield, whom, however, he defeated by a majority of 78. After serving the city in this capacity for eight years, during which time he did excellent work on many of the committees—including the Watch Committee—he retired from public life. He was the

principal of Messrs. J. A. Forrest and Sons, glass manufacturers Lime Street, which firm, it will be remembered, executed the stained glass windows in St. George's Hall. Mr. Forrest was a gentleman of artistic tastes, and his work as a pioneer of photography will long be remembered. He was not only distinguished in the use of the camera but his contributions to magazines on matters appertaining to his favourite pursuit were recognised as from the pen of an author. He was for a long period a prominent member of the Liverpool Photographic Society, and was greatly respected both in public and private life." The late Mr. Forrest was an early President of the Liverpool Amateur Photographic Association, of which he was a member from its foundation. In conjunction with Mr. James H. Rupp, of Bidston, he took great practical interest in the application of photography to astronomical purposes, and was the author of many communications to the Liverpool Association. He supplied in his personality the unique spectacle of more than half a century's continuous devotion to the practice and encouragement of amateur photography—a record, we should say, of its kind. Of very high character of heart and mind he will long be remembered with affection and esteem by those who follow him in the work of aggrandising photography in public practice and esteem.

BIRD-NESTING WITH A CAMERA.

At a meeting of the Rotherham Photographic Society held on Tuesday, September 6, Mr. J. W. Stamp, vice-president, gave an illustrated lecture on the subject of bird-nesting with a camera. Mr. Stamp commenced by saying that bird-nesting was regarded by the majority of individuals as simply a boy's pastime, but it was something more than a useless amusement. It possessed great possibilities of interest, enjoyment, and information. He knew of no hobby that brought an individual into such close touch with Nature, and revealed to him more of the hidden nooks and crannies where she stowed away her loveliness as bird-nesting. Commenced in a right spirit and prosecuted in an intelligent manner, it opened out avenues of recreation and pleasure hitherto closed. There was bird-nesting and bird-nesting. There was bird-nesting of the professional egg collector, who swooped into his net every egg of every species and regarded it as so much filthy lucre. There was the bird-nesting of the heartless lad who scoured every hedgerow, stream side, and woodland within walking distance with the sole object of stringing all the eggs he could find on a thread, and not content with this villainy, he pulled out every nest he met with to use as a football. With neither class had he (the lecturer) the slightest sympathy, and he considered that the strongest and most repressive measures that could be brought to bear none too strong. It was owing almost entirely to these two classes of individuals that many of the rarest and most beautiful species of birds had become or were rapidly becoming extinct. Some had already gone, never to return, and others were rapidly following in their wake. It was impossible to say how much they owed to birds. Not only did the birds in spring and early summer provide some of the sweetest music that could possibly greet one's ears, but they cleansed the air, irrigated and fertilised the soil, and served in various ways to make life more beautiful and enjoyable. Imagine, if they could, the condition of the atmosphere without the swallow, the martin, or the flycatcher, or the state of the fruit trees without the tit-mouse family. Those little scavengers would commence at one end of the orchard and taking the trees in rotation, would pursue their labours as orderly and methodically as a party of human beings, destroying insects, grubs, and larvæ as they went, and if in their onward march they did destroy a few fruit buds, well, they had it on the highest authority that the labourer was worthy of his hire. Then the rook family followed the ploughman up and down the furrow, and, as he turned up the soil, cleared away the slugs and filth in a manner that no human contrivance could accomplish. In those and many other ways the birds worked cheerfully, willingly, and incessantly, and they should regard him as an enemy of his race who did anything to destroy or exterminate them. There was, however, one style of bird-nesting that not only needed no justification, but, on the contrary, had much to commend it, namely, that which was prompted by a sincere and earnest desire to increase the knowledge of the birds, the nests they built, the eggs they laid, the lives they lived, their habits, and their uses. If an individual actuated by those motives would start out on the crisp mornings of the early spring, and pursue his wandering in an intelligent and systematic manner, he would soon find his cor-

tions of birds and bird life undergo some radical changes, while ideas of Nature and Nature's ways would be considerably increased and enlarged. In a particularly striking way Mr. Stamp proceeded to describe from his own experience many of the habits of birds had made a point of studying—the wonderful construction of their nests, the beautiful markings of their eggs, etc., and the places where they established their homes. Proceeding to describe his photographic outfit, Mr. Stamp said it was of the ordinary amateur's variety, and quarter-plate in size. He had confined his attention to subjects that would be found on the ground or within a few feet of it. If, however, the bird-nesting photographer intended to climb the top of the tallest tree with his camera and tripod strapped to his back, or had a desire to tempt Providence by dangling at the end of a rope 200 feet from everywhere, he (Mr. Stamp) had no advice to offer. Mr. Stamp concluded his lecture by showing an extensive series of lantern slides, made from negatives of birds' nests. They were excellently produced, and their charm was enhanced by the racy descriptions which were furnished.

Exhibitions.

KODAK EXHIBITION.

This exhibition of prize pictures and others sent in for the last Kodak Amateur Photographic Competition is now open at the Kodak Gallery, Strand, London, and will remain open until December 17. About 100 pictures are exhibited and the whole series makes a most interesting collection. This widely-advertised competition was probably the largest photographic prize scheme ever inaugurated, and brought in 25,000 pictures from all parts of the world. They were adjudicated on by Sir Wm. Abney and Messrs. J. Craig Annan and Frank Atcliffe, and the work throughout was held by them to be of a very high standard. We have already published in these columns a full list of prize winners, which included names of prominent workers from all countries, speaking well for the ubiquity of the Kodak. Prints of every shape, size, and colour are exhibited in remarkable profusion, and what is particularly interesting to note the excellence of the smaller prints produced by the Kodak cameras of the Brownie type. This fact should prove distinctly encouraging to the beginner with these little cameras.

The collection of prints is admirably displayed on a series of easel partout mounts, and the entire display reflects great credit on the energies of Mr. B. Alfieri, to whom, we understand, the trying out of this part of the work is due. The entire results displayed are produced throughout entirely with Kodak products, and must serve as a striking advertisement for the firm.

Particularly interesting are the prints that have been specially produced to show the orthochromatic qualities of the Kodak plates and the N.C. film. These examples show all the usual practical tests applied, in the shape of flower groups, colour charts, and cloud effects, etc., and the results are extremely striking and conclusive. Numerous attempts at something more than the usual snapshots are also in evidence and pictures with distinct artistic feeling are strongly represented. Another excellent idea, due to Mr. Alfieri, is the grouping of the whole of one competitor's work (although entered in many classes) in one frame when the average has been consistently good and thought worthy of this attention. In this way groups of first-class work by well-known workers are to be seen in a manner that permits adequate comparison.

Among those we noted whose work had been thus treated were Messrs. C. Cadby, whose delightful studies of weeds and flowers are always acceptable, Will. A. Cadby, and Mrs. Barton, whose characteristic figure work deserve special praise. Some small nude studies by P. S. Greig and E. B. Vignolas, taken with the Brownie camera; some wonderfully luminous groups of Algerian children by Emil Lechon (Breste), and other work worthy of note by S. R. Carter, Ward Muir, Fisher Ward, J. C. Warburg, Eustace Calland, E. R.

Bull, C. J. Reade, F. W. Gregg, A. Miller, W. Deeley, Miss Tomlinson, W. A. Hensler, A. Richmond, Miss Kate Smith, Walter Clutterbuck, A. Bedding, Walter Zimmermann, T. Brogden, Herbert Bairstow, Miss M. C. Eames, and H. Ledermann, while excellent comparative results of experiments with the orthochromatic qualities of the Kodak films are exhibited by Fred H. Evans with a series of photographs of backs of books; D. J. Cartwright, of Boston, whose examples of cloud work should be conclusive for the landscape worker; André Callier (Ghent), W. J. Mitcheson, H. G. Lancaster, and Dr. E. J. Rose (Charlottenburg).

All the pictures that were awarded the bigger prizes are really fine examples of modern photography, and nobody inspecting the exhibition will have much fault to find with the awards, from the larger prints which take prizes in the enlargement class, to the smallest—a tiny blue print measuring $1\frac{1}{2}$ in. by $\frac{3}{4}$ in. (E. Hoppé), looking much like a postage stamp. The gallery will be open to the public from 10 a.m. to 6 p.m., and on Saturdays from 10 a.m. to 2 p.m., and no charge will be made for admission. Every country visitor to London bent on seeing the Royal and Salon should certainly include this third exhibition in their programme.

EXHIBITION AT NEWTON ABBOT.

MR. PASSMORE EDWARDS, the Cornishman, is famed in his native county for acts of similar character to the famous Scot, Mr. Andrew Carnegie, in that he is the donor of many public buildings, mainly free public libraries and other edifices associated with education. In memory of his mother, who was a Devonian, and born at Newton Abbot in that county, he has presented the town with a free public library, and under the same roof the Urban District Council have, by arrangement with him, placed the technical schools of the town. The premises are a very fine, imposing pile, of which the late Mr. Silvanus Trevail, of Truro, was the architect. They opened last month. A committee asked Mr. Charles R. Rowe, of Cockington, Torquay, to get together a representative exhibition of pictorial photography from well-known workers. The show was the best yet seen in that part of Devon, and was a great education to the many photographers who visited it, and a surprise to the general public, which had up to the present not had opportunity of looking upon high-class work. In association with the same object Mr. F. W. Geary, of Newton Abbot, a very skilful amateur with a reputation locally for fine work on Dartmoor, invited amateurs of the town and neighbourhood to form a section, and the result was in every way satisfactory.

Naturally, the loan exhibition proved a great attraction, because the contributors to it were, many of them, unknown locally, but the work shown speedily commanded attention. To this we will first refer.

Dr. Grindrod was represented by some very charming examples of artistic work, all of which drew marked attention and observation from visitors, especially "Going to the Meadow," a man driving a flock of sheep, the arrangement of which was altogether admirable and enjoyable. This picture was, perhaps, the most popular in the exhibition, and deserved this expression of favour. "Cutting Oats" was also a very much appreciated picture, vieing with "Hauling Timber" in general esteem. "The Village Scholar" was a figure study of an oldish man reading, very capably thought out and of excellent work. There was fine vigour and life in "Wracking in a Spring Tide," a shore study. "Below the Weir" was a study of a fisher, the strength and quality of which was somewhat marred by the patch of light near the fisherman's head. A. J. Anderson contributed some very artistic works, standing out among which was "The Close of a Stormy Day," a group of fishermen on the quay at Plymouth when the grey of the day had come. It was produced in gum, and this medium had given the artist scope for strong work. "Twixt Mist and Freeze" and "The Mists of Dawn" were two studies of the sea and fishing craft, of strong pictorial quality and excellent atmospheric effect. He had a clever study of a child—"In Deadly Earnest"—busy at work lacing her boot, an experiment in local toning on platinum, and a very interesting example of good technique. His "The Pine Branch" was quite Japanese in treatment and very clever in selection, a pine branch silhouetted against a soft distant landscape and sky. "In the Mist of Dartmoor" was a skilful study of this famous Devon moorland, giving very fully the feeling of space and distance, and

the clever way in which a group of cattle had been dealt with shows Mr. Anderson to be a master of the craft. Arthur Marshall was represented only by two works, unfortunately, but these were greatly admired. The subdued religious tone and character of "Prie Dieu" deeply impressed everybody, and especially those who were either of artistic temperament or were sons of Sol or Photos. It was, as we have always thought, a work of great skill and ability. "The Love Letter," a study of a quaintly dressed lady, who is utilising the solitude of a glade to read her missive, is highly pictorial, the pose natural and easy, and the composition a fine lesson in such ways. Mr. Marshall is to be complimented upon his fine taste in harmonious and well-thought-out mounting, to which many excellent photographers do not give that attention which is due, and to their own interest. Rev. H. R. Campion's high reputation as an architectural photographer ensured that his contributions would be worthy. They were a splendid lot, of which, perhaps, the most artistically perfect, in the matter of composition and arrangement, was "Quomodo Delixi" (ps. 119 v. 97), with its memorials of the dead, the pathway to the church door, and the figure of the priest within the porch. His "Norman Work, a Contrast," in which dark contrasts with light, with splendid gradation in all, is a fine cathedral interior study. "Lux Benigna," a quiet, reposeful study of windows and tombs in a great church, is a very fine example of judicious selection and fine technique. His other contributions are "The Dog Gates, Haddon Hall," and "A Memory of Bygone Days," both charming pieces of work. The fine technique of this worker was a great lesson to local photographers. A. M. Fellowes-Pryne is represented by excellent work; of them "Qui Vive?" a study of two terriers on a sandy seashore in the wet sand, of which they are reflected in a silvery soft way. The work is very happy. "Homeward Bound" and "Overhauling" are two shore studies, the last in which figures occur. His "Evening" is perhaps a little choked up in the shadows, but is an interesting scene. Miss Rodway's "Grey" is a quiet grey study of a quiet stream passing by the walls of an ancient church, over which a fine fir throws its shade. Her "Where Erme Flows Silently" is a very striking scene on a well-known Devon river, charmingly chosen. She is also represented by an interior church scene, "Pulpit, Dittisham Church," a very beautiful example of carved work, photographically of the best technique. Miss Marillier's flower studies are very fine, especially the studies of "Chrysanthemums." Carslake Winter Wood has several very excellent and artistic things—"Kenton Church," a study of the south door, very beautiful; "Church of Our Lady and St. Denis, St. Marychurch," a beautifully graduated example of interior work; and "Midday Quiet," a study of a country village at the noontide, when things are still, an artistic selection. Miss G. Rodway has a very pretty study of child life on the Riviera, "Un Soldo?" and a "Schopper"—a German student's beer jug, in which the half tones and modelling are very well rendered indeed. C. J. King's contributions, representing sea-bird life and scenes in the Scilly Isles, are characterised by great care and very fine technique. Artistically, "On a Summer Sea" and "The Approaching Storm" are the most enjoyable, and the latter is a fine striking view of strong sea, rocks, and a very stormy sky. Graystone Bird was represented by his very well known and successful "Good Morning," "Good Night," and "The Order of the Bath," all very charming child studies.

In response to Mr. Rowe's request, Kodak, Ltd., were good enough to send some very fine enlargements, some of the most striking of which were John H. Avery's scenes in Morocco (which attracted a great deal of attention). Others were fine architectural work, good portrait and figure studies, and some striking work done by the Panoram. This collection did much to enhance the value of the pictorial character of the exhibition.

The work contributed by residents of Newton Abbot and neighbourhood was got together by Mr. F. W. Gerry, and are a very fine even lot of praiseworthy artistic quality, as a whole, and certainly creditable to all concerned. W. W. Palmer's Alpine scenes and a landscape with sheep are probably his best, though he has a study of a fishing fleet that is strikingly original. C. L. Vicary's snapshot work is good, and shows the eye of an artist. He has a clever lot of the "South Devon Hounds" and of a "Hurdle Race." A. W. Searley's range of subject is very wide, and he is very successful in most of his work. He has scenes in Switzerland, Germany, Austria, Italy, Norway, Spitzbergen, and Iceland; and in mountain work he has

certainly managed to do well with difficult subjects. Of these, pictorially, may be cited "The High Hills are a Refuge for the Wild Goats," and "Brigue, Simplon Pass." He has church interiors of good merit. B. T. Nunn's "South Devon Folgoat, Brittany," and "Carved Work, Cathedral of St. Leon, Brittany," are most creditable and very attractive examples of architectural work. Of E. Brook's contributions, the best scenes in "Bradley Woods, Newton Abbot," each of which, he would gain in quality by being of larger size. G. Bell is a very considerable contributor, and the best of his work is seen in the "Old Mill, Ogwell," "Combe-in-Teignhead," and "Old Yarn," the latter a transcript of one of the delightfully picturesque narrow streets in that city. F. B. Wily has some dainty little lantern slides of many of the scenes represented in his prints. Gerry also contributed a splendid lot of slides of flowers, sea, Dartmoor, and of other places in Devon. He gave each evening lantern exhibition, including, besides these named, some examples of the best-known lantern-slide makers.

FORTHCOMING EXHIBITIONS.

- September 14-15.—Cambridge Photographic Society. Hon. Sec., T. J. Sowden, "Sunny Side," Guest Road, Cambridge.
- September 16 to November 5.—Photographic Salon, Dudley G. Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.
- September 20-28.—Newbury Photographic Society. Hon. Sec., E. J. Forster, Guildhall Club, Newbury.
- September 22 to October 29.—Royal Photographic Society's Ninth Exhibition, New Gallery, Regent Street, London. Sec., A. W. W. Bartlett, 66, Russell Square, London, W.C.
- September 29.—Beverly Photographic Society. Hon. Sec., Morley.
- October 4.—Whitehaven Y.M.C.A. Zoar Photographic Exhibition. Hon. Sec., J. Hayward, 14, Albert Terrace, Whitehaven.
- October 15-29.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.
- October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn, Kettering.
- October 19-20.—Isle of Wight Photographic Society. Hon. Sec., J. Howard Burgess, 53, Pyle Street, Newport, I.W.
- October 19-22.—Rotherham Photographic Society. Hon. Sec., C. Hemmingway, Tooker Road, Rotherham.
- October 26-28.—Watford Camera Club. Hon. Sec., H. G. Foot, 3, The Parade, Watford.
- November 2, 3, 4, 5.—Newark Photographic Exhibition. Sec., L. C. B. Appleby, Barnbygate House, Newark.
- November 2-23.—Plymouth. Hon. Sec. Photographic Society, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.
- November 3.—Frome M.I. Photographic Society. Hon. Sec., B. J. Mitchell, 3, Willow Vale, Frome.
- November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.
- November 9.—Hackney Photographic Society. Hon. Sec., Walter Selfe, 70, Paragon Road, Hackney, London, N.E.
- November 15-19.—Sunderland Camera Club. Hon. Sec., Selby, 52, Frederick Street, Sunderland.
- November 17-18.—Braintree and Bocking Camera Club. Sec., W. H. Tilston, 81, High Street, Braintree, Essex.
- November 17-19.—Darwen Photographic Association. Hon. Sec., J. G. Thomas.
- November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
- November 22-23.—Ipswich Camera Club. Hon. Secretary, R. Sutton, 37, Henley Road, Ipswich.
- November 23-25.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.
- November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.
- November 25-26.—Ilford and District Photographic Society. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarnock Road, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Road, Dennistoun, Glasgow.

December 2-3.—Southsea Photographic Society. Hon. Secretary, J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairstown and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Stage, Blairstown.

February 21, to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Cot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxia. 68 prizes for users of Coxia. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

THE Observatory of Harvard University will soon possess the largest telescope in the world—namely, the 5ft. aperture reflecting instrument constructed by the late Mr. A. A. Common. Before Mr. Common's death, Prof. Pickering, the director of Harvard Observatory, had some correspondence regarding the telescope, but the price was prohibitive. A few weeks ago, the professor learned that it could be secured below cost, and a recent anonymous gift of \$4,000 the university made the purchase possible. The negotiations were conducted with Mr. Common's son through Prof. Turner, of Oxford, and preparations are now being made to send the instrument forward. It is nearly twice as large as the famous Lick telescope, which has an aperture of 36in.

New Apparatus, &c.

The Dai-Cornex Cameras. Sold by Messrs. R. and J. Beck, 68, Cornhill, London, E.C.

Under the name of the Dai-Cornex Cameras Messrs. R. and J. Beck are placing upon the market a series of nine models of magazine plate hand cameras, differing in their lenses, shutters, and various adjustments, but all as far as the essential novelty goes designed on a new principle whereby they can be loaded and unloaded in daylight. Like most lasting inventions the idea is simple, the plates are held in sheaths of thin metal as in other magazine hand cameras, but each

Fig. 1.

sheath (see Fig. 1) is provided with a channel or groove which fits the one behind it in such manner that if a number are placed on top of each other the pile may be exposed to light without any fear of fogging the enclosed plates. Twelve plates placed in a dozen sheaths, and provided with a thirteenth sheath in front to protect the foremost plate, are held together with a band, and are thus placed into the camera (see Fig. A).

Fig. 2.

The band is pulled off (see Fig. 3), the door of the camera is closed, and the camera is loaded. The plates are changed one by one by turning a handle at the side of the case. As soon as the dozen plates have been used the camera may be opened in daylight, and the pack of exposed plates removed in safety and the band replaced, which holds them together as a pack (see Fig. 4). Three sets of sheaths accompany

Fig. 3.

each camera and as many more as may be required can be obtained. The Dai-Cornex has no disadvantages as compared with the ordinary box model plate cameras and has the additional quality that they can be loaded in daylight. Models A, B, and C are fixed focus cameras, models D, E, F, G, and H are supplied with a focussing adjustment and the Cornex Index. Model A has a single achromatic lens, model

B a periscope lens, models C and D the Beck symmetrical lens, model E a Beck double aplanat lens, model F a Beck biplanat lens, model F1 a Beck-Steinheil unifocal F/6, model G a Beck-Steinheil orthostigmat F/6.3, model H a Beck-Steinheil unifocal F/4.5. By this system of daylight loading a dark room can be dispensed with as a sufficient number of plates can be carried in their sheaths for an entire holiday,

Fig. 4.

and for those who do not develop their own plates it is of special value, as the sheaths can be sent with their plates to be developed to the dealer, who will return the sheaths reloaded with plates. Such a complete series of cameras can scarcely be fully described in the space at our disposal, but a postcard to Messrs. R. and J. Beck, Ltd., will obtain a full illustrated description by return.

"Seltona" Court postcards. Sold by the Leto Photo Materials Co., Ltd., 9, Rangoon Street, London, E.C.

These dainty little cards are prepared with the same emulsion as the well-known "Seltona" self-toning papers, and print out in precisely the same manner, giving, with very little trouble, excellent prints of a good colour. The cards are $3\frac{1}{2} \times 4\frac{1}{2}$, and have rounded corners, and on the back have the usual postal announcement and a space for a message. The cards are printed either under a mask, or the entire sensitive surface can be utilised if thought necessary. The printing is carried considerably deeper than the finished print is to be, and for warm brown tones soak the prints for a minute or two in clean water, and place in the fixing bath as follows:—Hypo, 1 oz.; water, 10 ozs. Fix for about ten minutes, then wash for one hour in running water or eight to ten changes. For purple and blue tones soak the prints for a minute or two in clean water, and place for seven to ten minutes in the following:—Common salt, $\frac{1}{4}$ oz. (or a good teaspoonful to $\frac{1}{2}$ pint of water); water, 12 oz. Rinse in clean water and fix as above. To ensure permanence, a fresh solution of hypo should be used for each batch of prints. Should there be any fear of the hypo being acid, add a pinch of bicarbonate of soda to the solution. The real colour and brilliance of the print is only arrived at when quite dry, it cannot be judged while still wet. The makers state that the surface of "Seltona" is sometimes apt to discolour a short time after manufacture, due to the gold contained in the emulsion. This discoloration, however, makes no difference whatsoever to the finished print, as the yellowness disappears entirely in the fixing solution.

Patent News.

The following applications for patents were made between August 29 and September 3, 1904:—

Stereoscopic Photographs.—No. 18,672. "Improvements in the process of making line composite stereoscopic photographs." (Date applied for under Patents Act, 1901, September 17, 1903, being date of application in United States.) Complete specification. (Frederic Eugene Ives.)

Lens Stops.—No. 18,694. "Improvements in stops and diaphragms for photographic lenses." (Theodore Brown and Ernest Osman Brown.)

Cameras.—No. 18,815. "Improvements in photographic cameras." (George Russell Nicholls.)

Paper.—No. 18,890. "Method of production of photographic paper and the like." Complete specification. (Paul von Garainow-Trauttenberg and Max Leopold Fabian.)

Slides.—No. 19,010. "Improvements in and relating to photographic change slides for daylight loading." Arthur Augustus Brooks and George Andrew Watson.)

Film-packs.—No. 19,038. "Improvements in or relating to photographic flat film packs, and in the packing of such films, and cases or holders for said packs." (Newton Livingstone Scott.)

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
19.....	Southampton Camera Club	<i>Some New Photographic Instruments.</i> Mr. F. G. Ward.
19.....	Ilford and District Photo. Soc.	<i>A Holiday on the Norfolk Coast.</i> Part I. Mr. E. A. Gollidge.
19.....	South London Photo. Society	<i>Photographic Methods of Ilford.</i> Mr. W. T. Wilkinson.
20.....	Croydon Nat. Hist. & Scien. Soc.	Ordinary Meeting. Exhibition of Lanterns with Periscope.
20.....	Sheffield Photographic Society	<i>The Norman Churches of the Ilford District.</i> Mr. James R. A.R.I.B.A.
20.....	Blairgowrie and Dis. Ph. Assoc.	<i>Bromide Printing.</i> Demonstration by Mr. D. G. Monair.
20.....	Nelson Photographic Society	Members' Print Evening.
2.....	North Middlesex Photo. Soc.	<i>Intensification and Tinting of Prints.</i> Mr. F. A. Haylett.
21.....	Everton Camera Club	<i>Bromide Enlargements.</i> Demonstration by The President.
21.....	Watford Camera Club	Competition—"Eventide."
22.....	London and Provincial P.A.	Discussion on C.C. Papers.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION

A MEETING of the General Committee was held at 51, Baker Street, W., on Friday, 9th inst. Present, Messrs. F. A. Bridge, Alfred S. H. Fry, Wm. Gill, Wm. Grove, H. E. Hull, Percy Lankester Mackie, E. Scamell, and Lang Sims. Mr. Alfred Ellis presided in the chair. The date of the annual general meeting was fixed for Friday October 21, the meeting to be held at the London Photographic Society at 8 o'clock. It was arranged that in addition to the ordinary business of the meeting a tentative scheme for the granting of certificates to operator's assistants, etc., should be laid before the members and their opinions taken thereon, also that a discussion should be invited upon the suggestion of Mr. H. Snowdon Ward contained in the September number of "The Photogram" of the Institution of a benevolent fund for photographers. Report was made of the numerous applications for advice and assistance received during the recess which had been dealt with by the Emergency Committee. Further consideration was given to the Examination of Assistants scheme.

M. PAUL RENOUARD's love of truth has often made him suffer from physical discomfort. When making sketches at the Paris Exhibition he squeezed himself into all sorts of uncanny hiding places where he could observe and portray the various types in all their natural characteristics, and the result was a wonderful series of life pictures of the people who stood out strongly among the thousands of visitors. Whatever subject he has in hand no trouble is spared that he may get the absolute effect of light and atmosphere, and realise and distinguish individuals in relation to their environment. In the current number of the "Studio" an example is given of his enthusiasm and love for actuality. In the private chapel of the Invalides lie, under triple lock and bar, the hat and sword which Napoleon wore at the battle of Austerlitz. These precious relics are so highly valued that foreign Sovereigns are practically the only strangers admitted to the chapel, which is situated in the basement of the Invalides. When the Emperor and Empress of Russia were in Paris they visited this sacred place, and the scene supplied Renouard with the material for a splendid picture. In the foreground of this canvas the Emperor and Empress stand examining the relics, Felix Faure waits by, and beyond this group rises the huge statue of Napoleon. The execution of this notable painting severely tried the artist's courage. For many hours at a time he was locked in the chapel, "the living occupant of the vast edifice. It was winter, and in order to keep even moderately warm he had to work muffled up in blankets from head to foot. There was no means of escape until the official charge of the Invalides returned in the evening with the keys and released his voluntary prisoner." Such artistic fervour is rare these days of photography and the indolence it engenders.

News and Notes.

THE Metatype Company, of 238A, Seven Sisters Road, London, N., announcing the introduction of a new series of metatype plaques and papers.

Mr. F. F. DOWET, of 33, Fumival Street, Holborn, London, E.C., has been appointed sole agent for Monckhoven's carbon tissues, transfer papers, etc.

THE proceedings and transactions of the Croydon Natural History Scientific Society for the year ending January 19, 1904, have been issued. Reports of the various sections are given, and many of the papers read from time to time are reprinted, the volume being several admirable illustrations.

THE prospectus and class time-table of the twenty-third session (1904-5) of the Polytechnic Technical and Continuation Schools have been sent us. The Photographic School opens on Tuesday night, October 18, in the large hall, when a lecture will be given by Mr. Edward Farmer, entitled, "The Making of a Photograph." There will be no charge for admission.

WATFORD Camera Club's second annual exhibition will be held at Corn Exchange, Watford, on October 26, 27, and 28. There will be five open classes, and medals will be placed at the disposal of judges, Messrs. J. H. Gear and J. A. Hodges. Particulars and entry forms can be obtained from the Hon. Sec., H. G. Trayfoot, The Parade, High Street, Watford.

WE have received from the Crown Photo Mount Works, Percy Street, Rotherham, some tasteful specimens of greeting cards. These, in addition of photographic prints, which may be either pasted or "slipped in," are intended to form substitutes for the conventional Christmas card during the approaching season for such things. They are excellently adapted for the purpose, and we can recommend readers to apply for price lists and specimens to the above address.

SECRETARIES of photographic and other societies should send for a copy of the list of lectures supplied by the Lecture Agency, Ltd., of the Temple, Strand, London. It will be strange if they cannot find their winter programmes at least one item amid the galaxy of what therein available. The agency publishes each year this list of leading popular lecturers and entertainers who are available for engagements. It contains portraits, details of subjects, and all other necessary information.

THE London County Council announces that the evening classes held at the various polytechnics, technical institutes, and schools of art will be reopened towards the end of the present month. The evening classes previously conducted by the School Board will be reopened the enrolment of students on Monday next. Scholars under sixteen are admitted free to all schools, and in sixty-five schools no fee will be charged to any students. Any persons who desire to make themselves acquainted with further particulars of the classes are invited to ask for a pamphlet from the schoolkeeper of any of the Council's schools.

CRIPPLEGATE Photographic Society.—This Society commenced their season in their well-appointed room in Cripplegate Institute, September 5 with a demonstration of "Cross Swords" pigmenter and Paget's self-toning, given by Mr. H. Gordon Stollard. The very good results were shown, and especially for those who have gone beyond the P.O.P. stage. The demonstrator laid special stress upon the ease with which local development and suppression of unnecessary detail could be obtained, and in this respect the paper somewhat resembles "gum," although the ease with which it can be worked is much greater.

PHOTOGRAPHY to Beautify Public-houses.—The Central Public House Association has received through Mr. R. E. Macnaghten, of the Manian Public House Trust Association, the sum of £25 from an anonymous donor who wishes the money to be spent in decorating one of Earl Grey's Trust public-houses with framed photographs of Tasmania. The object of the donation is both to give a refined tone to the public-houses and to bring before the customers in a striking manner the beauties and advantages of the Colony for would-be

emigrants. The photographs will probably be placed in the Huts, Wisley, Surrey, and the Plumes, Park Royal.

THE Private View at the Twelfth Annual Exhibition of the Photographic Salon yesterday disclosed many novelties in photographic eccentricity; much that calls for a second inspection; and some really clever work in multiple gum printing. We understand a greater number of works than usual was submitted but fewer have been hung. The tone of the entire show, however, with the exception of occasional gleams of sunlight, and colour for which we are grateful, is rather depressing. It is worthy of note that of the 223 pictures on view (by 97 exhibitors) no less than 83 are American—having been selected by the American members of the Linked Ring, and 27 are from other foreign sources. The remainder are English.

THE Free Portrait Scheme in Ceylon.—A correspondent writes to the "Ceylon Advertiser":—"The Island has lately been flooded by prospectuses of a French firm, promising to the holders of these documents a life-size crayon portrait for the mere acceptance of the same as a present. The old proverb "Le monde veut être abusé!" evidently seems to be the motto of these gracious donors, and it is, I think, the duty of the Press to warn the too credulous public, on possible and almost certain frauds, in this matter. Any one who has remarked the absolute silence on the framing question will not be surprised if on receipt of a nasty caricature by post or agents, a claim is made on him "for the frame," which will render the whole adventure a too expensive one.

THE Royal Photographic Society's Exhibition at the New Gallery opens its doors to the public on Thursday next. The private view and soirée are on Wednesday. We hear that this year's show constitutes a record in the way of entries. Over 2,000 photographs have been sent in for competition in the pictorial section alone. We extend our sympathy to the members of the Selection Committee. It is interesting to note that the new regulation limiting the number of entries by each competitor to six has had just the opposite effect intended. Instead of curtailing the total number of entries it has had the effect of considerably augmenting them. Every exhibitor has apparently felt it a matter of duty to send the full number. We understand, also, that the quality of the work submitted is above the average, and a great many good things, particularly in the invitation section, will meet the gaze of the visitor to this year's exhibition.

PHOTOGRAPHY is admitted to be of great value to the sciences, especially to astronomy, but the debt may be repaid by the accurate knowledge gained by the labours of workers in this science. The "Observatory Magazine" for the current month states that an astronomer at Harvard University is making a very patient investigation of small photographic details, and finds, for instance, that there is a difference in photographic action depending on the temperature at which the plate is exposed, and, secondly, that the sensibility of the plate increases in a slight degree with its age. One great difficulty that astronomers have to surmount is to find a scheme of correlation between photographic and visual brightness—the brightest star does not always give the largest image on the photograph, as might indeed be expected, since it is the blue end of the spectrum which is most effective in photography, whereas the rays of all colours go to make up the visual image.

"I HAVE been reading some scientific lightning stories with the keenest interest. It seems," writes Dagonet in "The Referee," "that a woman struck by lightning while looking at a cow had a photograph of the cow reproduced on her chest by the lightning. A man standing near a sacred picture was struck, and the picture was reproduced on his back. The new method of photography is hardly likely to be popular with private sitters. But imagine the possibilities. Think of the thrills now available for sensational romance. Fancy the joy of the melo-dramatist who for four acts has allowed the innocent man to be falsely accused of the murder of the lock-keeper's daughter, when he arranges for the hero to tear aside the villain's waistcoat in the last act, and point to the picture of the murdered girl on his shirt-front. N.B.—This situation is registered at Stationers' Hall and in the United States of America according to the Act of Congress. Pirates, beware."

THE prophecy of Sir William Ramsay, speaking to the members of the Society of Chemical Industry at St. Louis on September 8, that science was on the eve of discovering the "origin of the ordinary

elements," if it be fulfilled, would appear to bring us very near the solution of the Riddle of the Universe. Since the discovery of the properties of radium, its power to transform itself into helium, and so on, it has been evident that a new direction has been given to scientific thought. But if this expected discovery really comes about we shall be rather sorry for science. It will be in the position of the old sportsman, to whom a solitary jack-snipe afforded food for powder for years. At last, one unlucky morning, the bird flew into the shot, and the sportsman wept bitterly: his sole joy in life had gone from him. However, we can console ourselves with the thought that, if this scientific mountain top be scaled, endless peaks will yet be seen from its heights to stretch ahead of the ardent climber after knowledge.

To Save Thames Scenery.—It was announced on Saturday last, on the authority of Alderman Charles Burt, J.P., the Surrey County Council's representative on the Thames Conservancy Board; that the Board of Trade have refused their consent to the plans of the Thames Steam Tug and Lighterage Company of building a dock and other works on Lot's Eyot, opposite Kew Gardens, for the repair and building of barges. Residents of the Lower Teddington Road, Hampton Wick, have petitioned the Conservancy to do all in its power to prevent the carrying out of a proposal to convert a portion of the grounds of Cambridge House, Hampton Wick, into a wharf. Cambridge House is situated immediately opposite the Canbury Gardens at Kingston, in one of the prettiest reaches of the Thames. The Hampton Wick Urban District Council are expected to take the matter up, as also are the Kingston Corporation, who spent a large sum some years ago in laying out the Canbury Gardens, which are among the finest on the Thames.

A New Beauty Spot for London.—The new Tube railway, which is to run from Charing Cross *via* Euston to Hampstead, is a commendable enterprise in so far as it will make the northern heights accessible to all at the most moderate outlay. Fortunately the owners in the present case, whose land the County Council desires to ransom, are the Eton College trustees, and, meeting those who are working for the public in a generous spirit, they have agreed to sell some eighty acres of the debatable land for the sum of £39,000. Towards the total purchase money about £33,000 has already been collected, and the Council are very anxious to secure the comparatively small remaining amount before the term expires during which they have option of purchase. With the eighty acres added to the Heath and public property a beautiful view would be saved for all time to a city not too rich in such possessions, and the thousands who will doubtless use the new Tube, especially on great holidays, would find themselves on arrival at once in the midst of a splendid playground teeming with as many photographic possibilities as the famous Heath itself boasts of.

A PHOTOGRAPHIC Competition.—The Architectural Association Camera and Cycling Club is holding a photographic competition which closes on October 1, before which date all photographs should be sent to Mr. Gilbert H. Lovegrove, the hon. secretary, at the offices of the Association, 18, Tufton Street, Westminster. The competition is confined to sets of photographs adapted for the purpose of architectural study, and is open to members of the architectural profession and all members of the Architectural Association. Each set should consist of not more than twelve prints, and should illustrate one subject or class of subjects. A competitor may submit any number of sets. The photographs will be approved by the Committee of the Camera and Cycling Club as having reached a fair standard of technical excellence, and will then be finally adjudged by a gentleman, not a photographer, who is an expert in architectural tuition, and who will be chosen by the President of the Architectural Association. His name will be declared before the end of March. Copies of the winning prints by a permanent process must be deposited with the Architectural Association before the prize of three guineas in the form of books or apparatus is presented to the winner.

BEN Nevis Observatory.—Ben Nevis Observatory will be closed next month. The directors explain that their reason for this decision is lack of funds. The annual cost of maintenance of the Ben Nevis and Fort William Observatories is about £1,000, towards which £350 is granted by the Treasury. The directors have communicated with Mr. Balfour on the subject, the committee appointed to inquire into the adminis-

tration by the Meteorological Council of the Parliamentary grant of £15,300 per annum having stated, it appeared, that only £3 required to ensure the continued maintenance of the observatory. A grant of £600 was asked for from the Government. Mr. Balfour, in his reply, expressed regret that the Lords of the Treasury could not entertain any proposal which would involve the placing of the charge for the maintenance of the observatories on the public. The Council was prepared to continue the grant of £350, provided that some public body in Scotland was willing to undertake the support of the observatories on their present footing. The directors, in their reply, pointed out that they neither knew of any public body in Scotland able to do what was suggested; nor could they make a fresh application for funds to the general public.

The Chancellor of the Exchequer has appointed the following men to serve as members of a committee to inquire into the duty-free alcohol for industrial purposes:—Sir Henry Primrose, K.C.B., C.S.I., chairman; Professor Sir William Crookes, F.R.S., Sir W. H. Holland, M.P.; the Hon. J. Scott-Montague, M.P., Lothian D. Nicholson, Esq.; Dr. W. Somerville, Dr. T. E. Thorpe, C.B., F.R.S.; Thomas Tyrer, Esq. The terms of reference are:—"To inquire into the existing facilities for the use, without payment of duty, of spirits in arts and manufactures, and, in particular, the operation of section 8 of the Finance Act, 1902; and to report whether the powers conferred upon the Commissioners of Customs and Revenue by this section permit of adequate facilities being given for the use of spirits in manufactures and in the production of power, or whether further facilities are required; and, if it appears to the committee that the present facilities are inadequate, to advise what further measures could be adopted without prejudicing the safety of the revenue derived from spirits and with due regard to the interests of the producers of spirits in the United Kingdom." All communications should be directed to Sir Henry Primrose, K.C.B., at Somerset House, Strand, W.C.

FILM Notes.—The current number of the "Barnet Record" contains the following useful hints in reference to film manipulation. The film which has been soaked in water will take much longer to develop than one which is placed dry in the developer. This is due partly to the dilution of the developer, and partly to the fact that, as the gelatine is saturated with water, the developer penetrates it but slowly. The wetted film will take at least half as long again to develop as one that is dry. If there are any sections to be under-exposed, when a complete spool is being developed, an attempt should be made to force development. The film should be rinsed and fixed as soon as the correctly exposed sections have been developed. Those which have been under-exposed will be in the best condition for intensification. Forcing the development will spoil all the exposures. Development of the complete spool is carried out in a special dish made for the purpose, or in an ordinary dish with a movable porcelain bridge standing in it. The principle is the same in all cases; the roller or bridge, whichever is employed, holds the film under the surface of the developer. The celluloid of the film is kept next to the roller, and by alternately raising and lowering each end, the whole surface is wetted in turn. When the film is cut into sections, a convenient way of holding each section flat in the developing dish is to place it face upwards on a plate of glass of the same size, and to clip it at each end with a narrow india-rubber band.

MR. FREDERIC GEORGE KITTON, well known as a writer on Delineation and his illustrators, died in London on Saturday at the age of eighty. Mr. Kitton was born at Norwich in 1856, and was the son of the late Mr. Frederic Kitton, hon. Fellow of the Microscopical Society. He received his education at a private school at Norwich and was trained as a draughtsman and engraver on wood by the late Mr. W. L. Thomas, of the "Graphic." He adopted literature as a profession, and more especially that branch of literature which is concerned with the illustration of books. One of his earliest publications of this nature was a memoir of Hablot Knight Browne, entitled "Phiz," which appeared with reproductions of Browne's work in 1882. "John Leech, Artist and Humourist," followed in 1883. The chief work of his lifetime was devoted in one way and another to Dickens, the Autograph Edition of whose works he edited. "Dickensiana" were published in 1886, and among other books

one subject were "Charles Dickens, by Pen and Pencil," which appeared in 1889, "Dickens and His Illustrators," 1898, "Charles Dickens, his Life, Writings, and Personality," 1902. Mr. Kitton published a memoir of his father, Mr. Frederic Kitton, in 1895, a centenary memoir of the musician Zechariah Buck in 1899. He was a frequent contributor of both articles and drawings to the "Journal" and the "Magazine of Art," and had been honorary secretary of the Hertfordshire Art Society since 1900, and one of the secretaries of the Hertfordshire County Museum.

DEPARTURE in high-power microscopy which is the invention of J. W. Gordon merits more attention than it obtained at its exhibition at the Royal Society. When high magnification is attempted by a series of lenses arranged in the conventional manner, the emergent beam of light which enters the eye of the observer is so small that vision is deficient, owing to the fact that the pupil of the eye is not entirely filled with light. It is consequently apparent that in order to obtain satisfactory results in high magnification the emergent ray should be expanded in such a way as to fill the pupil of the eye. This result is achieved in J. W. Gordon's microscope. It comprises an ordinary microscope with an eccentrically-rotating glass screen, with a finely-etched surface placed in the view field. This is viewed through a microscope which has an object glass of half an inch, by means of which a further magnification of one hundred diameters is rendered possible. The transmitted emergent beam is expanded by a ground glass screen, so that it fills the second microscope; and there are no imperfections in the magnifications. Mr. Gordon has divided a diatom to ten thousand diameters, and its structure is perfectly clear and defined right to the edges. A comprehensive view of the extent of this excessive magnification may be gathered from the fact that if the eye of an ordinary house-fly were magnified on the same scale it would cover an area of three hundred and twelve square feet. The purpose of revolving the ground grained screen is to prevent the grain thereon from becoming visible and thereby interfering with the magnifying of the object under observation, as it is not in contact with either of the microscopes, there is complete absence of vibration.

PHOTOGRAPHY on the Norfolk Broads.—A good many readers will regard the Norfolk Broads district as a holiday resort, and it will be painful to them to notice how in the last few years public opinion, and amongst them those of the photographer, have been misled, writes a correspondent to the "Oxford Chronicle," whose pledge of them dates back at least twenty years, when most of the waterways were as free as the seashore to the fisherman as was the yachtsman, but since that time there has been a terrible change. The "Broads" were first brought into repute by the publication of a boys' holiday book by Christopher Davies, entitled "Swan and her Crew," and in the succeeding year I made a visit, which has been regularly followed up with very few exceptions, to this delightful quarter. Since that time the Broads have been gradually closing up to the public, South Walsham being the last to go, and soon there will be nothing left except rivers to sail on, fish in, or photograph over. There was a beautiful sail in the northern portion, up the Bure or north river, through Heigham Sounds and Meadow Dyke, across Horsey Mere up Waxham Dyke, which runs in close contiguity to the beautiful dunes beyond which lies the sea. It was the orthodox programme to take this course to reach the sea, either landing at South Walsham Bridge or at Palling for the short walk across the sand-dunes to indulge in a sea bath. Picture my horror last week when I discovered Waxham Dyke deserted and a notice board intimating that it was now considered a "private canal" (according to the line), and that one was not allowed to moor a boat, land, tow, or navigate to the aforesaid "private canal." Some wag has signed at the end of the notice "or breathe" and really that conveyance will have to be taken into account later on. It is a sparsely populated district, and the bucolic mind is sluggish, but I know of districts where such notice boards would not have survived. Waxham Dyke is as much a public highway as Fleet Street, the Strand, and is, indeed, the only waterway by which the villages of Waxham and Palling can be reached at all. Why doesn't somebody take the matter up?

Correspondence.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—Will you allow me space to say that at the annual general meeting of the Association, which will be held at the Royal Photographic Society, 66, Russell Square, by kind permission of the Council of the Society, on Friday, October 21, the committee will submit the outlines of their scheme for the granting of certificates for photographic operators, assistants, etc. The difficulties of meeting the requirements of employers and of arranging for the attainment of certificates by employees without almost prohibitive conditions have been found to be very great, and the Committee would feel obliged if members who are interested in the subject would make it their business to attend and assist in deliberating upon the matter. They would welcome also communications from non-members. At the same meeting Mr. H. Snowden Ward's appeal for the institution of a Benevolent Fund for photographers will be discussed, especially in its bearing upon the legitimate work of the Association.

May I add a reminder to members that the annual subscription is now due.—I am, etc.,
September 12, 1904.

WILLIAM GROVE,
Hon. Secretary.

"THE FUTURE OF PROFESSIONAL PHOTOGRAPHY."

To the Editors.

Gentlemen,—Your correspondent, Mr. Arnett, writing under the above heading in your last issue, raises some points with which some of your readers—especially those who happen to be employees—may be at variance. With the main portion of Mr. Arnett's ably written communication the writer agrees most cordially; these are certainly truths that "he who runs may read." The construction, based upon the continued appearance of an advertisement by an eminent firm, is certainly one way of looking at the matter. There may be, however, other points of view, quite as likely to be the right.

Is it not possible that a firm, known by its continual advertisements, would be avoided by operators of the best class? They may reasonably suppose that such firms do not keep their men very long, and would prefer to remain in a house less eminent but more reliable. Another reason for this curculation of advertisements on the part of the leading firm may have been that pressure of business caused them to forget to withdraw the ad. The same pressure might have also induced them to forget that they had engaged two men instead of one for the same position; and, further, the said pressure of business may have been the cause of sending on one of their old employees to fill the vacant post! The uninitiated may think that the leading firm might have done this at first, saving themselves trouble, and the employees in question a good deal of injustice. But, alas! the uninitiated were ever ignorant. (Please, gentlemen, describe the last paragraph as a Joak, or some of your readers may take it quite seriously.) In the second instance quoted by your correspondent, surely plenty of good retouchers are to be found for a salary of 45s. per week? Perhaps the noted firm wished to secure a special man and would have lured him by an increased offer—not quite what he asked maybe. The writer fears that the lack of competent assistance in the photographic profession is largely caused by some of the principal houses who take apprentices, with premium, and fail to give them any real knowledge of the business. Because a lad has served his time at So-and-so's, he is taken on by another firm much less eminent, which firm is greatly disgusted to find that their acquisition can varnish negatives and change plates, his other knowledge being practically nil. If a really good operator is difficult to find a first-rate employer is a much greater variety. When double dealing, meanness, and lack of true business principles have disappeared from the high places of photography, then, and only then, will the talented and faithful worker be found to match the altered conditions of employment.—Yours faithfully,

September 9, 1904.

OPERATOR.

PHOTOGRAPHIC COPYRIGHT.

To the Editors.

Gentlemen,—I cannot help thinking it unfortunate in the interests of the photographic profession that you should have appended your editorial note to the letter under the above heading in the issue of September 9. It has always been the policy of the B.J.P. to defend the photographer against those illustrated papers who reproduced his work without fee, or permission, and if I mistake not the statement has many times been made, in reply to queries, that it is not necessary to state on a photograph whether it is the producer's copyright or not, and that reproducers reproduce it at their own risk. The number of invitation sittings is now so great that this risk is not a small one. I do not see that the strong and loyal support the B.J.P. has always given to the P.C.U. should be allowed to cover any accidental breach of the Union's rules or of the copyright laws, and it seems to me that many of the illustrated papers will, and all of them might, say that the "splendid irony" lay in the B.J.P. preaching one doctrine when they chanced to be the aggressors, and another when itself stumbled.

A further point comes to my mind whilst writing. So many of the best photographers, those who produce individualistic work, are liable to suffer at the hands of customers who get these portraits copied at cheap rates, that the tendency in such businesses must eventually be for the photographer to reserve the copyright to himself by agreement signed at the time of sitting. This, of course, could only be done by men sufficiently strong, and is only worth while to those who charge relatively high prices. The artist selling a portrait may not, perhaps, reserve copyright, but he has no interest in reproduction unless a painted replica is required, and then he is usually given the commission. Quite recently a case came under my immediate notice, a chemist and dealer showing me some pictorial postcards he had been doing from the carbon photographs a local firm supply at three guineas a dozen. The price he charged was 4s. 6d. a dozen, but I must admit that in this case the quality of the work was so poor that the scheme must have proved a failure. But the possibility is there.—Yours truly,

C. H. HEWITT.

Gateshead-on-Tyne, September 12, 1904.

[It is true that the BRITISH JOURNAL OF PHOTOGRAPHY has always defended the photographer against those illustrated papers that reproduce his work without fee or permission, and always will, but it has never been an advocate of the system of "invitation sittings." Our correspondent entirely misses the point of our append, which was written solely in the interests of photographers themselves. It simply amounted to the suggestion that they should make their non-paying sitters acquainted with the rudiments of copyright law. Any risk of newspaper aggression would, or should, then be removed and much of the antipathy towards the invitation sitting system which to our knowledge is felt all over the country and reacts upon the whole of the photographic profession, would, no doubt, disappear. If this matter had been handled with greater tact years ago we in all probability should not now contemplate the spectacle of the great newspaper concerns being as far as possible their own photographers, and doing a vast amount of work which need not have been diverted from legitimate professional sources. Our strong and loyal support of photographic copyright by no means blinds us to the instances in which it has not been worked to the best interests of the photographic profession.—Eds. B.J.P.]

To the Editors.

Gentlemen,—Reverting to your remarks annexed to my letter which you were good enough to insert in your last issue, I cannot help thinking that your own case is an exceptional one, really between yourself and the firm holding the copyright of the photograph in question, so I am sure you will not expect me to refer to it beyond regretting that any misunderstanding should have occurred. Nevertheless, I feel I must take exception to what you say as to the "Illustrated Press Editors running the risk of being pounced upon for fees they didn't contemplate incurring."

My experience is that they are quite capable of taking care of themselves, as the circular which I quoted clearly demonstrates; besides, I have seen several similar ones which are sent when asking for photographs from celebrities direct.—I am, Sirs, yours faithfully,

A MEMBER OF THE P. C. N.

September 12, 1904.

THE GOLDSMITHS' INSTITUTE PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—I very much regret to have to advise you that society will cease to exist on the 29th instant owing to the fact the Goldsmiths' Company will discontinue its technical and recreative work here on that date, the building having now been handed over to the University of London for other purposes. I should feel exceedingly obliged if you would be kind enough to notify this fact to the University of London for other purposes. I should feel your columns for the information of our various friends and correspondents in photographic circles. Any further communications in reference to the society may be sent to me at my private address: The Laurels, Slaithwaite Road, Lewisham, S.E.—Very faithfully yours,

September 10, 1904.

A. H. DOWNEY, Hon. Secretary.

THE NEW "STEADMAN" SYSTEM OF EXPOSURE AND PLATE SPEED MARKINGS.

To the Editors.

Gentlemen,—In Mr. Alfred Watkins' remarks re my new system as outlined in this paper on August 5, I fear that he has not considered the real meaning of the word "system." If he will in some dictionary he will find that it is not a series of new truths but rather, as mine gives it: "An orderly combination, or arrangement, as of particulars, parts, or elements into a whole." In assuming that I claim newness for the different truths he assumes more than I. And even in the arrangements of the parts of the system I claim newness only for those parts which differ from the old systems now in use. Any one should know that the parts which are similar could not be new, and this I considered so self-evident I must confess I did not think that any one would come out to contend for it. I realise fully the good qualities of Mr. Watkins' methods, and especially along the line of factorial development do think, however, that although his method of exposure is sufficiently exact to save every plate exposed, it is so because of very great latitude of all emulsions, and not because of its grasp of the truths of light and subject, especially the latter. It is not sufficient to not lose a plate or film in exposing. On the contrary, it is absolutely essential for the worker to be able to know exactly what would be a normal exposure (in the sense of a correct exposure for a certain subject in hand), and then he is able to vary the exposure as to draw down the half-tones of the subject into the shadows of the finished photograph, or raise them up close to the high lights by a predetermined amount of under-normal or over-normal exposure. The fact of exposure is logically the first place for fixing the tone curve of the finished photograph, and time it shall be so used by all who claim at all to have grasped the truths of photography.

Mr. Watkins thinks that my subject-table (which is the arrangement in the system) is too complex. Is it as complex as Nature, from whose face the vibrations come to the lens? The system is as nothing. The question is: "What is the character and condition of Nature, with which we have to deal?" The subject-table only divides each class of subjects into three divisions, as, for example, regular exteriors. When there are light-colored objects in the picture-field the divisions are only between "bi-eye," "objects in middle distance," and "objects in foreground." Surely this is not too complex. In my opinion it is the limit of simplicity, and, in truth, necessary to the development of the worker who is commencing the practice of photography along the line of seeing Nature, and discriminating between the different structures of picture-fields. It will lead to a closer study of the foreground and middle distance, and with the other subjects the same. Surely the subject with objects in the middle distance would require only one-half the area of diaphragm with the same time of exposure as would a subject with objects in the foreground. And a bi-eye view would only require one-half that of the middle-distance view. In fact, I only intend by this differentiation to suggest control of the subject by the mind through giving each its exposure of diaphragm, which sticks to it permanently so long as the same plate or film is used. And when any worker has the system in hand he will discriminate still more finely than I have in the arrangement of the system.

As to using the "first-appearance" method for measuring activity of the light, it is all a question of using it until a cer-

confidence is inspired. It is simply a "fixed amount of work" for light to do, and this constitutes a measurement of that light. Practice gives absolute control and confidence. The strong point of all the established systems is the differentiation of the speeds of emulsions by giving to each speed a diaphragm which is supposed to be correct (with the intensity factor as exposure), and is to the strong point, for each emulsion. This is done notwithstanding the ordinary worker uses the same plate for years at a time. They do so, by incorporating the "comparison" method of tinting, select arbitrary paper and tint as standards, and it is necessary to the meter in order to use the method. The strong point of the new "arrangement of truths," or system, is that a subject-table may be provided which is correct for the especial plate that the worker uses, and once in his possession he need not alter it until changes to some other emulsion. This table differentiates between subjects for the logical reason that the subjects change in character most with every exposure. My system agrees with Nature, therefore.

Furthermore, by accepting the "first-appearance" method of tinting, I obviate the necessity of a meter which will do much toward bringing light measurement into more common practice. The standard is established, then, not by any arbitrary act which would have to be harmonised to obtain a standard, but by Nature itself, when one colour is distinguishable from another, can be seen by the whole world with like precision. The acceptance of the standard of paper that is in use, moreover, tends to accept the possible and present "practical" rather than to hank for the too dimly in the future "theoretical." I know that any man who has devoted himself to investigation as Mr. Watkins has receives his greatest pleasure in the intellectual, and not from the commercial, side of his business. I have felt this to be true in reading Mr. Watkins' books and articles, and I take the liberty of assuring the reader that I shall not condescend to the discussion of the small things of photography, as has too often been done in the pages of this journal. While seventy-five per cent. of the work of all beginners is absolutely lost, there is no time for such discussion. The question to-day of photographic thinkers is, and must be, along higher lines. From A to Z photography needs unification and numerical expression. I believe that I have arranged these matters in a manner that will be acceptable to mathematicians and physicists, and shall present the system to the public probably in the coming year in the form of a school text-book, arranged for the last two grades in the common high schools of the United States. I am looking more for co-operation and sympathy in Europe than in the United States, for the public mind is more studious, and I shall hope that every one interested in the advancement of photography, and the raising of it to the dignity of an exact science, will refrain from hasty and unjust criticism until I may bring to light this complete system. Any differences of opinion, however, may be discussed with benefit, and I shall feel honoured in answering any criticism that can lead to a better understanding of the truth.—Sincerely yours,

September 1, 1904.

FRANK MORRIS STEADMAN.

STALE PLATES.

To the Editors.

Gentlemen,—I do not think there can be much doubt as to the answer to "Enquirer's" query. The case is provided for in Sec. 14 (1) "The Sale of Goods Act, 1893," which states: "Where the buyer, expressly or by implication, makes known to the seller the particular purpose for which the goods are required, so as to show that the buyer relies on the seller's skill of judgment, and the goods are of a description which it is in the course of the seller's business to supply (whether he be the manufacturer or not), there is an implied condition that the goods shall be reasonably fit for such purpose."

Further, in the same Section, under Sub-section 2, it is provided that: "Where goods are bought by description from a seller who deals in goods of that description (whether he be the manufacturer or not) there is an implied condition that the goods shall be of merchantable quality."

Obviously the sale of plates is within the ordinary course of a photographer's trade, and the presumption is that a purchaser requires them for the purpose of taking photos thereon. The dealer, therefore, I think, is justifiably held to imply that the plates he sells are

reasonably fit for photographic purposes. I do not see that he could escape this liability by pleading they were sold under their trade name, as it is very doubtful whether this defence could be held to apply here at all.

As regards a warranty on the part of the manufacturers, it is the custom of dry plate makers to enclose a slip inside each box of plates, stating that they are sold without a warranty of any kind. In a recent case it has been decided that manufacturers cannot, by simple notice apart from express contract, escape liability under implied warranties; but, apart from this, "Enquirer" would have, probably, no case against them, as their relationship to him, he having bought through a dealer, is too remote. His remedy is to sue the dealer for breach of implied warranty of fitness and claim damages. Since, apparently, he entered into no special contract with the dealer his measure of damages would only amount to the price of the plates.—I am, Sirs, yours faithfully,

ARTHUR V. KENAH.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

E. Allen, Ash Villa, Rustington, Worthing. Photograph of Sir H. Harben.

J. T. McNamara & Sons, 32, South Street, Romford. Photograph of Dagenham Cycling Carnival.

J. P. Tilley, 28, New Briggate, Leeds. Photograph of twenty-five of the Bolton Wanderers Football Club.

R. Thirrell, 21, Bridge Road, Stockton-on-Tees. Photograph of Group of Sunderland and Norton Cricket Teams combined. Photograph of R. H. Spooner. Photograph of J. T. Bosanquet. Three photographs of R. H. Spooner, J. T. Bosanquet, and G. L. Townsend together.

D. Murray, 49, Queen Street, Wolverhampton. Photograph of casting pig-iron, Springvale Works, Staffordshire.

A. E. Gompertz, 248, South Frederick Street, South Shields. Two photographs of W. A. Purvis.

F. Poppleton, 64, Urban Road, Hexthorpe, Doncaster. Photograph of the Doncaster Rovers Football Team, 1904-1905.

P. Greenhalgh, 223, Eccles New Road, Weaste, Manchester. Photograph of view in Sordley Park, Salford.

J. N. HAGGITT.—Two hundred grains is correct.

WILKINS.—Very sorry, but the answer to your question is beyond us.

J. A. C.—How is it possible for any one to give an opinion of apparatus they have not seen? All we can say is that it seems a lot for the money.

C. C. W.—Messrs. J. J. Griffin and Sons, Ltd., 20-26, Sardinia Street, Lincoln's Inn Fields, London, supply the camera you mention. It is known as the Pocket Poco A.

RED TONES.—"LIGHT" asks: "Can you tell me of a paper that will give red tones matt. surface not carbon, and also the formula by which it must be toned or developed?" In reply: The "Carbona" paper will yield red tones. It requires no toning—simply fixing.

SILVER STAINS.—A. FISHER asks how to remove silver stains from a negative. In reply: To remove silver stains from a negative immerse the negative for five minutes in salt, 2 oz.; hydrochloric acid, $\frac{1}{2}$ oz.; water 20 oz. Then wash well and refix, or use thiocarbamide, 5 grs.; citric acid, 10 grs.; alum, 10 grs.; water, 1 oz. Rub the surface of the negative with this, and well wash.

METOQUINOL.—"L. M." says "In making up this formula, a thin, flaky deposit is formed after dissolving the Hq. metol, and

sulphite. Of what is it composed, and may it be filtered off or is it of any value in development? I notice that it is soluble, and I therefore take it that if I made up my formula in a more dilute form it would not appear?" In reply: If the solution is of the ordinary strength there should be no deposit. Probably it is undissolved metal. Dissolve the metal first, using warm water if necessary, and then add the sulphite and hydrochinone.

USE OF NAME.—"STIGMATIC" says: "I shall feel obliged if you will kindly answer the following query. I have an engagement with a firm, in a town where I have previously been employed for several years, as managing operator, but my former employer, having disposed of his business, have I a perfect right to advertise and use his name without asking permission thus:—'Several years managing operator for Mr. X.'?" In reply: There is no legal objection to your doing what you propose, provided that Mr. X's name is not made more prominent than your own.

PLUSH FRAMES.—"ANXIOUS" asks: "Do you know of any houses that supply plush frames for mounting P.O.P. prints on to $\frac{1}{2}$ pl. prints, price per doz., and if any previous experience is necessary, as I have never done anything yet. If so, do you know of any houses that would undertake to do the work from own prints sent, as I am thinking of doing some?" In reply: Plush frames are supplied by all the large houses, such as Marion's, Houghton's, and the like. Very little experience is required for the mounting. Probably Messrs. Raines and Co., Ealing, would mount the prints for you if you do not do them yourself.

DEVELOPING P.O.P.—"SOTON" says: "I have very little time for printing my negatives during the day time, and can only put the printing frames out for a short time every morning before I leave home. Will you kindly give me the method for developing under-printed P.O.P., and is any special paper necessary." In reply: Any paper may be used. Print very lightly, then immerse the print for ten minutes in a 10 per cent. solution of potassium bromide. Wash well, then develop with—A. Hydroquinone, $\frac{1}{2}$ oz.; sodium sulphite, 2 oz.; water, 110 oz.; B. Potassium bromide, 15 oz.; sodium carbonate, 12 oz.; water, 110 oz. For use mix A 1 part, B 2 parts, water 1 part; then well wash, and tone and fix.

RESIDUES.—N. POWELL writes: "I have a quantity of old toning baths, and also hypo baths, in which both plates and prints have been fixed. I have saved them up, as I understand the gold and silver can be collected from them. Please tell me how to set about it." In reply: We are afraid that unless you have a very large quantity it will hardly pay for the trouble. You will proceed as follows:—Acidulate the old toning baths with nitrate or sulphuric acid, and add one-half the total volume of saturated solution of ferrous sulphate and boil; collect and wash the precipitate, which will be impure metallic gold. To the old fixing baths either add liver of sulphur and stir well, and allow to stand for two or three days with occasional stirring, and then collect the black precipitate, which will be silver sulphide, or add zinc filings or magnesium powder and stir well; the zinc and magnesium are dissolved and metallic silver deposited.

COPYRIGHT QUERIES.—"REGISTER" asks: "(1) Must every copyright print bear the word 'Copyright'? (2) What is the remedy if anyone copies a copyright print? (3) How long does the copyright hold good? (4) And, if it is not too personal, why do you require two prints when registering?" In reply: (1) No, not necessary. (2) The owner of a copyright may proceed against an infringer for (a) a forfeit or penalty of not more than £10 for every copy; (b) forfeiture of all copies and negatives, etc., used in their production; and, in addition, by special action may recover damages. To succeed against an infringer it is necessary to prove (a) that you are owner of the copyright; (b) that it has been "repeated," copied, colourably imitated," etc.; (c) that you did not give permission. Ignorance on the part of the infringer that the work was copyright is no defence in law. (3) Copyright continues for the term of the

natural life of the author and seven years after death. One for filing at our offices for reference and the other for authorities at Stationers' Hall.

BUILDING QUERY.—"NEMO" says: "I propose erecting a studio in the garden at the back of my house, but fear there may be some possible objection from the neighbours, as I want to carry the studio above waiting room and dressing room which would be on the level of the ground. This would mean a building 22 ft. long and about 18 ft. high. I should esteem it a great favour if you would advise me whether the next neighbour on the solid side of the studio could legally object to my obstructing his view by so doing? I have enclosed plan will perhaps explain the position of affairs. I may say both houses have been erected forty or fifty years and I do not deem it advisable to ask the parties whether they object or not until I know whether they can prevent the building being put up. Thanking you in anticipation." In reply: So far as we can form an opinion from the sketch enclosed should say your neighbour could prevent the building being put up. It would certainly obstruct his light and air, particularly that of the greenhouse. As the houses have been built long your neighbour is entitled to his "ancient lights."

STUDIO AND LENS QUERY.—"TROOPER" says: "1. I have a studio with side light only, from roof to floor, south-west, I should like as I get the sun all the afternoon. There are ordinary yellow blinds fitted to windows, and when the sun shines I get a kind of yellow halo between camera and sitter, which is very troublesome. I can get good effects easily when the sun is not shining, but have to give a full exposure always. Will you please say if white blinds would not be an improvement, and if another set of pale blue blinds, used in conjunction, or separately, would not prevent the halo space of in bright sunlight. 2. For the coming winter I shall require a quick-acting portrait lens for all-round studio work. Can you say which make and particular lens or lenses would best answer my purpose?" In reply: 1. By halo I presume you mean haze. If the glass is kept tolerably clean we should think you would not get that. Yellow blinds are very unusual for a studio. For the light you have should prefer medium green blinds. 2. A portrait lens as small as is made for cabinet pictures will be best for pictures of that size. See the advertisement columns.

In a picturesque description of the historic ceremony in the Lhasa Palace when the Tibetan treaty was signed, the special correspondent of the "Daily Mail" says:—"It is most fortunate that circumstances have compelled us to proceed to Lhasa and conclude a treaty in Potala itself. Had the treaty been made at Tuna, or even at Gyantse it is doubtful if the impression would have been so lasting or the results of the Mission so far-reaching." Some consternation was caused among the monks by the taking of a flashlight photograph of the signing of the treaty. They were reassured by the laughter of the Nepalese and Bhutaneses.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued in two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded.

* The frontispiece of the ALMANAC will consist of a portrait study specially taken by Mr. Furley Lewis and a list of the Royal Photographic Society's Exhibition. (1903).

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc.

The publishers ask us to remind advertisers that a large proportion of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion, order and copy should reach them without delay.

* IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that this year the entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1st next—a fortnight earlier than usual, so as to be well in advance of the Christmas publication season.

EX CATHEDRA.

The Two Exhibitions.

The opening of the Royal Photographic Society's Exhibition at the New Gallery, and the Photographic Salon at the Dudley Gallery during the past few days, marks the passing of another year of progress in the photographic world, pictorial and technical. The extent of this progress can be gauged by an inspection of the exhibits displayed at the two shows. The Salon with its avowed intention of cultivating the most advanced ideas in pictorial individualism, has succumbed entirely this year to the overwhelming work of the American and Continental schools, and the British element, containing though it does many sound and clever workers, appears quite out of the running in the presence of such an exhibition of efforts by the morbid-minded exponents of foreign gum printing. The broader aims of the Royal with its praiseworthy intentions and success in the furtherance not only of pictorial, but technical excellence, has again a show of interesting photographs that are refreshing to gaze upon for their straightforwardness. All the same, the foreign element of eccentricity has not been neglected, and in another room at the New Gallery this year will be found a wonderful collection of specially invited work from some of the most notable foreign workers in gum and colours that fairly out-Salones the Salon.

Ben Nevis Observatory. In our last issue the closing of the Ben Nevis observatory was referred to in a paragraph. A correspondent writing to the *Standard* one day last week expresses the regret of meteorologists that this observatory, situated on the top of the highest mountain in the British Isles, over 4,400 ft. above sea-level, should be closed because the Treasury will not increase the grant for it by a paltry £250 (£600 being all that is applied for). He in his letter calls attention to the fact that Germany and America are leaving us quite in the lurch in the matter of meteorology. It is true that the Meteorologic Council receive an annual grant of between £15,000 and £16,000. This is not a very large sum after all, but it is a question if this is expended to the best advantage. It will be remembered that a few months back the Committee appointed by a Treasury minute of a year or two ago to inquire into the administration by the Meteorological Council of its annual grant, made its report. It was to the effect that the Office should be reconstituted and placed under the control of the Board of Agriculture and Fisheries, the bodies most immediately interested in the weather. Whether this recommendation will be given effect to or not we are unaware, but the refusal of the full sum of £600 to keep the Ben Nevis observatory going would seem to show that the Treasury have no great sympathy with meteorology.

* * *

Another Picture Stolen. Thefts of valuable paintings seem to be on the increase; and what is more, the pictures, when stolen, are seldom recovered. One would not unnaturally surmise that such a thing as a valuable picture would not be easy to dispose of, for it would be of no use to anyone if it could not be shown in public. A picture is a very different thing from jewellery, precious stones, and the like, when they get in the hands of the "light-fingered gentry." The latter can be readily converted, but not so with paintings—they cannot be dealt with except in their original form. The latest theft is that of a valuable antique picture of The Crucifixion, of Grecian workmanship, stolen from the Cathedral at Osimo. It has been said that more than one stolen picture has found a home in America. The telegram, through Laffan's Agency, in announcing this theft, says that a Roman art dealer, who has business transactions with American and English collectors, is known to have lately visited the Cathedral, has been arrested on suspicion of having committed the theft, but the picture has not been recovered. The Government, it is said, has ordered a strict look-out for the treasure to be kept at all frontier stations. One would think, for the reason just mentioned, that a valuable painting, when stolen, should soon be recoverable, particularly as there are few such pictures that have not been reproduced by photography, and hundreds of copies of them circulated throughout the world, and would from them be at once recognised; yet that does not appear to be the case. No one, it might be imagined, would purchase a picture to hang, either in England or America, amongst his collection, or put into his gallery for sale, if he knew that it had been stolen—yet pictures are stolen.

* * *

Historical Photography. For obvious reasons Photography has not been the handmaid of History, as it has of other branches of knowledge. Scarcely more than half a century old itself, and only arriving at the years of discretion about three decades back, we could not expect it to do much in the historical line. But it will be very different in the future, and many earnest workers, with Sir Benjamin Stone at their head, are taking good care that future generations shall have photographic evidence of the events and episodes of to-day. One of the

most picturesque of historic ceremonies took place on the other day amid the barbaric splendours of the Palace at Lhasa, when the treaty was signed which is destined, we all hope, to put an end to our difficulties with Tibet. We can learn from the able descriptions by newspaper correspondents all about the brilliant tapestries and wall-frescoes of the chamber where the ceremony took place, and we are able in a measure to form a mental picture of the Amban and his suite, the Nepalese Resident and his following, the crowd of monks, and the group of British officers with their Sikhs, Pathans, and Gurkhas. It is a picture, however, which quickly fades from the memory like some scene at the theatre which we have admired and soon forgotten. But the historic event was photographed. We read that at the signing of the treaty some consternation was caused amongst the monks by the taking of a flash-light picture. The poor men must have been much startled by this explosive flash of light in the midst as were the visitors to Westminster Abbey the other day by the crackers which were let off by some miscreant in the building. We shall all look forward with interest to seeing a photograph taken of such an event under such dramatic conditions.

* * *

Postal "Cash on Delivery" and Photographers. A question was raised some months ago as to whether the system, prevailing in many countries, of the Post Office receiving cash payments for small parcels of goods ordered from tradesmen at a distance when the package is delivered should be adopted in this country. Judging from correspondence on the subject that has from time to time appeared in the daily Press, opinions seem to be very much divided on the point. Big concerns in large towns seem to be very much in favour of the idea, whereas tradesmen in small places are strongly opposed to it as being likely to cause injury to their business. Last week the Postmaster-General, in reply to an inquiry from a London house, said, in a somewhat ambiguous way, that he had considered all expressions of opinion sent to him, whether favourable or otherwise, the majority of which have been from traders or bodies discussing the matter from a commercial point of view. He now wishes for the views of a wider public on the matter—private individuals. In the pay-on-delivery system, through the Post Office, when adopted, we can see that it would be of great service to many photographers. Most have on their price list "Cash at time of sitting," but how frequently is this condition not enforced, particularly in country places! The result is that when the portraits are forwarded the photographer has often to wait a long time for the money, and not infrequently has a trouble in getting it at all, more especially when the pictures are sent, say, to neighbouring places. If the postal cash-on-delivery system comes into vogue the photographer would simply have to send pictures by post, and if they were not paid for on delivery they would not be left by the postman. In this way we see that the system would be of great service to photographers in all parts of the country.

* * *

Revolving Houses.

The *Lancet* last week in an article states that experts in hygiene are accustomed to lay a good deal of stress on the importance of correctly orientating dwelling-houses, so that they may receive the maximum amount of light and of protection from cold winds. Our contemporary further says experience has taught us to select as far as practicable a southern aspect for our houses, but, even when this is done, the fixity of the structure prevents our regulating the supply of sunlight to different rooms according to our varied tastes. The article adds that two French gentlemen, one a doctor

and the other an architect, propose to change all this, and they have designed a method of erecting houses on rotating platforms so that the building can be made to revolve in any required direction at any time. It appears that a gas or petrol engine is employed to move the platform, and if necessary it can be used to drive clockwork, which will enable the house front to follow the sun during the day. The article concludes by saying that there are difficulties in the way, but considers the idea worthy of the attention of British architects. What ideal houses these would be for photographers! They could be removed so that the studio, printing, enlarging, and other rooms could be illumined from any point of the compass, and at any desired time; hence, amongst other things, direct sunlight in the studio might be avoided at any season of the year. Revolving studios, per se, have been constructed in this country, and they are by no means uncommon on the Continent with those firms that make speciality of the reproduction of paintings. The studios have been abroad are wooden structures of considerable size; they are mounted turn-table fashion, and are easily rotated by two men, or even one, so that the picture to be reproduced can be illumined with light from any direction that may be desired. Much of this work, it may be mentioned, is done in direct sunlight, which with the revolving studio may be made to fall on the picture at any desired angle at any time of the day. It is needless to say that revolving studios occupy a good deal of room as the space required is a circle the diameter of which must be considerably more than the length of the structure. For this reason they cannot be availed of in confined situations.

* * *

above the snow-line.

The Alps have claimed this season more victims than their usual number of victims, and among them must naturally be numbered many photographers, for there is a charm about camera work amid the mountain peaks which is unique. Hence we find many accomplished workers who never take photographs of any other subjects. The mania for this sort of work cannot be understood by those who have not indulged in it, just as non-climbers can never understand what they call the foolhardiness of those who risk their lives amid the glaciers. There is, however, a certain class of visitors to the Alps which contributes largely to the annual death toll; people whose object seem to be that they can say to their friends that they have been there. They are not regular climbers, nor are they photographers, but they make it a rule to bring back with them, unless their career is cut short by untimely accident, a sprig or two of Edelweiss. This plant is supposed by them, and the idea is encouraged by the natives who sell it for fancy prices, to grow only in the most inaccessible places, and above the snow-line. So that its possession indicates that the owner has had the courage and hardihood to hang over his eye-lids over some precipice or other in order to gain the plant. Let us hope in charity that these eager hunters of Edelweiss will not be too cast down—we mean in a figurative sense—when they see a letter in the *Times* dispelling their fondest illusions with regard to this Alpine growth. With a penny packet of seed, we are told, Edelweiss will grow readily in any London back garden. And the writer adds, "To risk one's neck, therefore, for such a plant gives no title to the laurel crown of the hero, but rather to the garland that adorned Bottom's neck when the ass's nose was fixed on his head." The moral of all this is that if one wants to pose as a conqueror of many peaks, it is far better to take photographic negatives of them than to avail oneself of the negative evidence of the Edelweiss. An Alpine photograph cannot be faked, it must be taken up in the snow. It would be a mad thing to endeavour to obtain its counterfeit presentment from the

limited area of a metropolitan back garden, and by no stretch of the imagination could the London grimalkin be mistaken for the chamois. With the Edelweiss, however, it is different, and the penn'orth of seed will confer upon the suburban resident enough to satisfy the wants of many climbers without risking a single neck. Possibly a trade in cultivated Edelweiss for the use of those who like to be considered foolhardy, without the hardy, may be worthy of consideration for the future.

* * *

The Newest Postcard.

Many abortive attempts have been made to wed the photograph with the phonograph, and more than once we have been promised the representation of grand opera by means of the cinematograph, while at the same time our ears would be delighted by the corresponding sounds produced phonographically. All these anticipations of what might be have been doomed to ignominious failure, and the opera singers can still claim their princely stipends without any fear of a mechanical rival. The union of the photograph and phonograph has assumed a new phase. Grand opera is to be left alone, and we must be content with works of less grandeur. The photographic postcard is the medium by which the new departure is to be brought about, and the plan is certainly so ingenious in conception that it deserves to succeed. To be able to actually "speak one's mind" through the medium of a pictorial missive to a friend, and more especially to an enemy, is a consummation devoutly to be wished, and picture cards to enable one to do this are shortly to be placed upon the market by a French syndicate. And this is how it is to be done. To an ordinary pictorial card there is attached a transparent disc, presumably of celluloid, through which the picture can be as easily seen as through glass. This disc has been stamped while soft with a gramophone musical "record," so that when received through the post the owner slips it on a machine, sets the clockwork going, and hears the message sent by his correspondent. Briefly, it is the one of the uses anticipated for the phonograph, that of correspondence by sounds instead of written characters, adapted for the use of the million by the aid of the popular pictorial postcard. The portraits of well-known actors and actresses, as well as of music-hall celebrities, will be accompanied by celluloid discs bearing records of their most popular speeches or songs. The candidate for election to Parliamentary honours will send round his portrait by the thousand with extracts from the speech, written by his agent, which in former times he would have delivered *viva voce* at the hustings. Then there will surely follow some means by which correspondents can make these records for themselves, and an interesting point will arise for the lawyers as to whether a tirade of eloquent abuse, punctuated with flamboyant adjectives, spoken into a machine, can be regarded as a libel when ground out of another machine by the receiver thereof. Then there are endless possibilities opened up by this system for the ingenious advertiser. We shall no longer content ourselves with reading that a certain soap is "matchless for the complexion," but we shall have a portrait showing the fine texture of the skin so treated, while the fair one to whom it belongs sings the praises of the soap in the tones of a nightingale, so far as the gramophone is able to emulate that overrated bird. The additional cost of a thin celluloid disc is said to be trifling, but a question will arise as to the price of postage. At present one must add nothing to a postcard but the necessary stamp, and the addition of a celluloid disc would not be permitted. Our postal authorities will, however, have the opportunity of noting how our French neighbours get over this little difficulty. It is certain that if the idea of the sonorous postcard takes the

public by storm, the Post Office will see their way to relax their regulations. The introduction of the picture post-card must have brought much extra grist to the national mill, and if the new card holds out a hope of increasing the amount, its way will be made easy.

STORING NEGATIVES.

RETURNING to this subject, which we dealt with in part a little while ago, it will be wise to draw attention to one branch of it that has an important bearing upon the question of storing or non-storing. We have pointed out that this should be settled according to the wants of each business separately; no hard-and-fast line as to its desirability or not can be established. Strict economy in the conduct of a business being always a necessity, and doubly and trebly so in the present depressed state of the profession, every item of expenditure needs to be closely scrutinised, and the particular aspect that presents itself in regard to the storage of negatives is their insurance against fire. As every photographer knows to his cost, the insurance rates for photo studios and their contents is very high—unduly so, we hold, having regard to the risks—but if it be elected to exclude negatives a very much lower rate can be obtained for the whole contents of the building. This fact not being so well known as it should be, we have thought it desirable to bring it forward as an aid in coming to a conclusion.

With regard to the actual mode of storing to be adopted, the requirements to be fulfilled are ease in locating any particular negative and a minimum expenditure of time. For the carrying out of these everything must be done systematically, and in order. A collection of negatives of great intrinsic value becomes almost worthless if it requires hours of search to lay hands on a particular one. Naturally the first thing that presents itself to the mind is an index, and when it is remembered that storage implies the possibility of having replica orders from plates taken years ago, every member of the staff then existent being probably replaced, so that memory should form no part of this (or indeed any) system.

The index requires to be very complete as well as accurate, to contain not only the full name with initials, but the address of the sitter. It is a common and most desirable, though not universal custom, to mark the back of every print issued with its register number; but it is found that in a very large number of cases of re-orders a sample print is not available, and its number is unknown; hence the need for recording these details. As a further addition to the usefulness of the index in this direction we may describe a Register Book, our records attributing its invention and use, thirty or forty years ago, to one of the smartest business men who ever took up photography, the late Mr. Brown, of the well-known firm of Brown, Barnes, and Bell. This book was a companion to the index, and consisted of a large volume for pasting in a print from every negative in the index book. A sitter comes in to order replicas; has a hazy idea of when a particular picture was made, or which especially liked one of several taken about the same time is to be repeated. A reference to one or other of the register books puts the matter beyond doubt. To further the search in this direction it is an excellent plan, whenever a new year is begun, to interpolate the figures representing that year in each page of index and register books before adding the first number of the year. This seems a slight matter to name, but it will be found extremely useful in practice. As to the actual numbering the negatives themselves, before storing, little need be said. It should be done at

once—i.e., before printing by scratching with a sharp pointed instrument upon the film, or carried out by pasting near the edge, in a suitable position, a narrow slip of paper with number and name written on it. Books of labels may be bought with consecutive numbers at the end and blank spaces for names at the other. When seeking for a particular number in a batch this plan has great advantages over the scratching method, as there is no need to hold the negative up to the light. For the final racking many photographers pin their faith to the paper-bag plan, each plate being put into a bag with an index number written outside, and placed in one of a series of pigeon-holes arranged to hold any required number, the greater the number, the more the time needed in locating the required bag. By this plan the negative is preserved from dust and dirt. Others use the pigeon-holes in the same way without placing the plates in bags.

To preserve from dust others use the pigeon-holes in plain rows of shelves for packets of negatives wrapped in paper. A favourite method is to store the negatives in empty plate boxes, separating each plate from the next by a piece of paper to prevent scratching. These are then stacked on shelves on their edges, economy of wall space being subserved by arranging them with the longest edge on the shelf. Each box should be labelled at the outer edge with the first and last index number of the contents. Here let us observe that it is infinitely more convenient to put just ten plates in a box, not a dozen or more, because the box will hold them. When casting the eyes over the shelves it is surprising how much more quickly any required negative storage in boxes where, to save expense, strong wooden boxes are arranged side by side over the top of another in lieu of shelves, and an excellent plan it appears to be. It is, of course, advisable to have boxes of uniform size and substantial build. In the instance we refer to the boxes were empty cases that had been used either for Martell's brandy or bottles of champagne.

We reserve for final mention the most convenient, most costly of all—a number of shelves fitted with wide grooving. They are conspicuously numbered by tens, intermediate figures being left out so that the site of any plate can be found at a glance. The great advantage of this plan is that a place can be allowed in advance for every negative produced, and as soon as it is printed from the negative may be put in its own groove without trouble or delay, no opening of packets or boxes. It may be objected that they would gather dust, especially on the retouched plates, but this is not found to be the case, the more so that it is possible to purchase a retouching medium which negates dust. The chief argument against this system is its cost, but this will not amount to much annually, and will be further minimised by, after a number of years, removing the plates from their grooves and boxing them off above.

We have, of course, not attempted to give an exhaustive account of methods adopted, but those we have described above may be looked upon as typical and possible. Every one or other of our readers may be able to glean hints from their own practice.

MESSRS. A. W. PENROSE AND CO., of 109, Farringdon Road, London E.C., write:—Whilst thanking you for the kindly notice which have given of our publication of Von Hubl's "Three-colour Photography," permit us to point out that you have made a mistake stating that the price is 3s., whereas it is 7s. 6d. nett. The mistake has led to our receiving a number of orders with insufficient remittances. We shall, therefore, be obliged if you will, in the interest of your readers and as a favour to ourselves, make some announcement correcting the error.

THE BLEACHING PROCESS OF COLOUR PHOTOGRAPHY.

"Eder's Jahrbuch."

RESEARCHES of the author on the bleaching-out process of photography in colours have been continued during the past year. A great disadvantage of the original method (i.e., mixing the gelatine with hydrogen peroxide) is that the peroxide does not behave well with the gelatine. If the freshly-coated plates are allowed to dry quite slowly at ordinary temperatures, which at least twenty-four hours are required, the excess oxygen, which plays the principal rôle in the bleaching, escapes during the drying of the film, and the result is extremely insensitive plates. If the drying is effected at increased temperatures, so as to have the plates ready for use from one and a half to two hours at least, great changes take place in the gelatine, the film becomes dirty, and filled with oxygen bubbles. These difficulties may be overcome by bringing to the plate the oxygen necessary for the bleaching only just before use, which can be done by bathing it in the ethereal peroxide solution just before use. There is not much difference whether the gelatine is mixed with water or hydrogen peroxide. If it is mixed with the latter, then drying is best effected by artificial draught, but without heated air, which takes from six to eight hours; if, however, it is mixed with ordinary water, then they may be dried by warm air, and this may be done in from one to two hours. The plates, mixed with hydrogen peroxide and then bathed with ethereal peroxide solution, are rather more sensitive than those made with plain water only, the former plates must be exposed within three or four days of their preparation.

The necessary peroxide-ether solution for bathing the plates just before use is prepared by vigorously shaking 15 cc. of 10 per cent. aqueous hydrogen peroxide solution with 200 cc. of ether. This gives about a 1 per cent. solution of ethereal peroxide solution, which is the best sensitising the plates. As, after shaking up the mixture of ether and hydrogen peroxide, the water contains always at least thirteen times as much peroxide as the ether, the use of a 1 per cent. solution of the peroxide only gives about a 0.75 per cent. ethereal solution, which is not sufficient. The bathing of the plates must last at least five minutes; simply pouring the mixture over the plate is not sufficient.

In order to prevent the adherence of the coloured original film during printing, which must be done in diffused light, not sunlight, the film should be rubbed over with oil. For exposures in good summer light, and with the most powerful lenses, require from six to eight hours' exposure, and the film must be protected by a sheet of glass to prevent too long a drying of the film.

A useful recipe for the preparation of the gelatine colour solution is as follows:—

Soft emulsion gelatine	10 g.
Distilled water	100 ccm.
When the gelatine has melted there should be added with constant stirring	
Methylene blue BB (Bayer) (0.1 : 50 ccm. dist. water)	6 ccm.
Auramine conc. Bayer (0.1 : 50 ccm. alcohol)	1.5 ccm.
Erythrosine, Schuchardt (0.25 : 50 ccm. dist. water)	3 ccm.

Before mixing it should be filtered. The best sensitiveness is obtained by keeping the mixture for four or five hours at 25°C. If the gelatine is mixed with peroxide the quantities of the dyes are slightly different:—

Soft emulsion gelatine	10 g.
Hydrogen peroxide 10 per cent. sol. ...	100 ccm.

After melting at as low a temperature as possible, the following should be added with constant agitation:—

Methylene blue solution, as above.....	5 ccm.
Auramine blue solution, as above	2 ccm.
Erythrosine blue solution, as above	4 ccm.

After filtering the plate should be at once coated.

The author has not yet succeeded in preparing paper so that the dyes do not penetrate into the paper, which gives very insensitive preparations, so he uses opal glass with a rubber substratum, by which means the film can be stripped and transferred to paper.

The author has continued his researches on increasing the sensitiveness by various additions, but without result, and the persulphates still remain the best sensitisers, but the beauty of the colours suffers.

In isolated cases the author observed that printed plates could be further developed by repeated dipping in hot water. Under what circumstances this occurred could not be accurately determined, as sometimes it occurred and sometimes did not under absolutely identical conditions.

Warm water exerts an action on the film, which is interesting from several points of view. In many cases the bleached colours are regenerated when the image is treated with warm water. An instructive experiment is as follows:—A coloured print is bathed in formaline solution, and then exposed to strong sunlight till the colours have quite disappeared. If the plate is now dipped into hot water the colours are regenerated and the original coloured copy is again obtained.

Not less interesting is the formation of colours by light. It is known from the work of Oscar Gros, that when the leuco-bases of certain dyes are prepared, and these exposed to light; the original colour is regenerated from the leuco-base, and this regeneration is strongest when the leuco-base is illuminated by light of a colour complementary to the colour that is formed.

In spite of the apparent similarity of these experiments the regeneration of the colours in the experiments described by the author have nothing to do with the leuco-bases, because here there is no leuco-base, but probably a sulphur compound of the dyes. Many dyes, especially the blues, lose their colour in the dark when mixed with aqueous gelatine solution mixed with a small quantity of ammonium persulphate. If opal glass is coated with such a mixture, and the ammonium persulphate present in the film washed out after drying, and the still damp plate exposed, the colour is regenerated, and most vigorously in a coloured light complementary to the colour that is formed. If such a plate is exposed dry, no colour forms, but this immediately appears if the plate is bathed after exposure in lukewarm water. The formation of the colour is most vigorous where light has acted which is complementary to the colour that is formed. We have here to do with the beginning of a colour-forming process.

DR. R. NEUBAUSS.

A NEW washing apparatus for plates and prints has been designed by Emil Bachmann, of Erfurt. It consists of two tanks placed together at right angles, in each of which is a partition somewhat lower than the side walls of the tanks, and dividing the tanks into two divisions. This arrangement is suspended from an ordinary tap and is free to revolve round an axis. In the larger part of each tank are placed the plates or prints, fastened in with a folding frame. By opening the tap the part is filled with water until the height of the partition is reached, after which it fills the other part. The weight of the water in this portion then causes the apparatus to revolve, the filled tank being emptied and the other brought under the tap. The apparatus continues to work automatically and the plates are continually being washed with clean water, which is discharged as it becomes contaminated. The apparatus is simply an application of the principle adopted in the well-known Kipp weighing machine.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

FIRST NOTICE.

YESTERDAY, the forty-ninth Annual Exhibition of the Royal Photographic Society of Great Britain, opened its doors to the public, at the New Gallery, Regent Street. The Exhibition is to remain open until October 29. The private view on Wednesday afternoon (September 21), and the popular soirée in the evening drew a crowd of photographic notabilities from all parts of the Kingdom, and the success of both functions can be regarded as auguring well for the future of the show.

Amongst those present during the afternoon and evening we noted Messrs. George Scammell, Furley Lewis, H. Snowden Ward and Mrs. Ward, R. H. Anthony, Thomas Bedding, E. J. Humphrey, W. Downey, T. K. Grant, G. W. Norton, Hubert Elliott, H. Foulkes Winks, Sydney Keith, S. G. Kimber, F. H. Evans, Mrs. A. Jennings, J. Gunston, C. H. Oakden, P. Bale Rider, William Gill, Fred Marsh, P. Brotherton, W. Calder Marshall, Miss M. Donaldson, Rev. F. C. Lambert, B. H. Bentley, P. R. Salmon, Dr. Evershed, Miss Ackland, F. Martin Duncan, P. Ponge, J. Hay Taylor, J. H. Baldock, C. C. Cook, W. Kilbey, E. Sanger Shepherd, A. Haddon, R. Craigie, Kung Pah King and Family, H. Bedford Liemere, C. E. Kenneth Mees, Prof. R. Meldola, C. H. Austin, F. Beeson, Alfred Bedding, C. Welborne Piper, F. W. Gregg, Drinkwater Butt, F. W. Hindley, Miss Constance Ellis, A. W. W. Bartlett, J. H. Avery, W. H. Hayles, J. C. S. Mummery, F. J. Mortimer, Douglas English, T. E. Freshwater, R. Beckett, C. F. Juston, B. G. Wilkinson, W. E. Southcombe May, A. L. Henderson, J. Cadett, Arthur Marshall, A. R. Sargeant, T. Thorne Baker, Hedley Smith, Chen Ming Sheng, Yin Show Ling, and Pai Kwung, Attachés to the Chinese Legation, W. Sims, Dr. L. West, J. A. Sinclair, H. Wilmer, W. E. Debenham, W. E. Foxlee, R. R. Beard, Sebastian Davies, E. Shunemann, J. S. Teape, W. Gamble, J. B. B. Wellington, Alfred Ellis, A. Horsley Hinton, Hector Maclean, and E. Clifton.

This year's Exhibition, as a whole, with the exception of the brilliant display of American and Continental work in the invitation section, of which more anon, has nothing very original or striking to show in either the pictorial or technical sections, nor among the professional and trade exhibits. It is satisfactory to note, however, that no retrograde action has taken place, that the same healthy tone pervades the majority of the pictorial exhibits, and that although no new giants have appeared, the dwarfs of previous shows have evinced a steady, if not rapid, growth, and the result is an excellent all-round exhibition of good, sound photography, representing English camera craftsmanship at its best. Far be it from our thoughts to "damn with faint praise" so admirable a collection of photographic productions as are now presented for our inspection, but we seem to feel that English pictorial photography, of which this is a representative exhibition, is pausing awhile, and, like a sailing ship in stays, quivering uncertainly in the deflecting wind of criticism, steadies itself before plunging off with renewed vigour on a new tack, but withal keeping the same objective in view—the betterment of photography in general, as opposed to the aggrandisement of a few, whose affectations and personalities, although interesting and clever enough per se, are apt to have a warping influence, if taken in bulk, on the broader-minded policy pursued with particular vigour on this occasion by the Royal Photographic Society. The work from all parts of the world, depicting all styles of mannerisms and eccentricities collected together and exhibited this year in the South Room, serve to show to a great extent the position of pictorial photography abroad, and also in many instances will supply valuable object-lessons to the more ambitious English workers who cannot make up their own minds.

The technical and scientific section this year does not appear so strong as in previous years, either in quantity or quality,

but the apparatus show is good, and the professional section well supported again. A detailed account of these exhibits will be given later. We will chiefly concern ourselves for the present with a brief notice of some of the principal works in the pictorial section. This section, as in previous years, is in the West Room, and it would be difficult to secure a gallery for the display of so large a collection of photographs. Out of a total number of over 2,000 pictures sent in, 345 have been hung. The weeding out process must, therefore, have been very drastic. Six medals have been awarded in the pictorial section, and one in the technical and scientific. The recipients are: Pictorial:—Arthur Marshall; F. J. Mortimer; C. Austin; T. Lee Syms; Henry Havelock Price; and Ernest Boon. Technical and Scientific:—Arthur C. Banfield.

Dealing with the medalled pictures first, No. 1 in the catalogue, "Devotion," by Arthur Marshall, is the first recipient of this honour we meet with. The picture represents a figure kneeling at the foot of a statue of the Virgin and Child, and is treated with a masterly skill that altogether disarms any objection of repugnance that one might feel for the portrayal of this sort of subject by photography. The technical quality of this print is first class, and the contrivance of the light on the kneeling figure's face, occupying as nearly as possible the middle of the picture, is quite successful. The lines formed by the suppliant and the statue will be found to be particularly graceful in spite of the extreme narrowness and height of the frame which is the ornate thing of its kind in the Exhibition, and leaves absolutely no doubt that it was specially constructed for this picture. Marshall's steady progress along the lines of sound pictorial work displaying considerable personal feeling, culminating in this achievement is a matter for congratulation. The medalled picture we come to is No. 164, "The Reef," by F. J. Mortimer. As the title indicates, this is a sea-piece, and, most of this worker's studies of the sea, the endeavour is apparent to render something beyond a mere snap-shot of curling breakers and stormy skies. A poetical feeling is evinced in the delicate treatment of this particular subject, which represents a line of foaming billows breaking over an almost submerged reef, the effect of flying scud, foaming water, and squally sky is true to nature. The composition is curious, and strikes us as being a trifle weak, inasmuch as the highest light, the towering wave-crest, is as nearly as possible in the centre of the picture. The feeling of daylight, however, which it appears to be Mortimer's endeavour to bring into his sea-scapes is very much in evidence. Nevertheless, we think that at least one other of this worker's exhibits on the walls was deserving of recognition before this. The third medal goes to C. H. Austin for "Cape Dordrecht" (175), and is the least satisfactory of the awards. There is nothing really remarkable in this quite commonplace photograph of a Dutch quayside, with houses and shipping of the same sort of thing has been done over so much better, even in the present show. There is a peculiar heaviness about the print that appears unnecessary. The composition is not remarkable, and the recession of planes is distinctly faulty. A triangular piece of dark roof in the top left-hand corner is a mistake. It is, however, unaffected photography, and a sunny effect that is not displeasing. The reflections in the water are also good. The next medal winner in the catalogue is T. Lee Syms, with one of his typical portraits of a Lancashire lass. We wonder if this award was made by artificial light? We raise this query in view of the exceedingly bad specimen of spotting that is apparent in quite large patches on this otherwise nice photograph. It is entitled "A Country Girl," and the young lady's bonnet-strings, coming over her shoulder, evidently formed an obtrusive white line that was undesirable. Why Lee Syms, who is, we understand, a professional photographer, could not have painted this out in a colour that matched the rest of the picture we cannot conceive. It is particularly ob-

when the bright morning light is on this wall of the gallery. There is excellent modelling in this portrait, but the face itself is not particularly pleasing, and has a puffy look that does not attract on close inspection. Henry Havelock Price's "Dr. H. O. Percy," winning the fifth medal, is a splendid piece of work. It can rightly be described as a "speaking likeness," and no fault can be found with the photography, the subject, treatment, or the composition. The modelling of the face is admirable, and the masterly management of the white collar and fur on the coat is worthy of considerable study. The white mount for a portrait in so low a key is not quite happy, and tends rather to upset the value of the face, but this detail can be overlooked in the presence of such first-class work. No. 317, "Convalescent," a charming little child study by Ernest G. Boon, secures the sixth medal, and it is quite a triumph in low-pitched tones. It represents a pathetic-looking little girl in bed, and the title is evidently inspired by fact. The rendering of the textures of the bed hangings is what probably calls for most praise. This is very skilfully done, and Dr. Boon is deserving of all praise for the restraint shown in the treatment of the whole. The little girl, who is placed rather low in the picture, is excellent, one might, indeed, be forgiven for saying beautiful, and the entire picture is delightful to contemplate.

The medal in the section devoted to scientific and technical photography is secured by Arthur C. Banfield's extremely clever series of photographs showing a comparison between a jump of one foot in height as executed by a dog and a cat respectively. This series of thirty-two prints, sixteen of each animal, illustrates the successive motions of the animal at approximately equal periods. The photographs illustrate the animals' ability to judge with great nicety the amount of power required to clear the obstacle, effected in both instances with a remarkably small allowance of space. Each animal alights on one fore-paw only, the other being advanced before the moment of contact. Each animal alike takes a step forward with fore-paws alone to bring the hindquarters free of the obstacle as they fall. The exposures are: Cat, 1-1,200 sec.; dog, 1-5,100 sec.; and the whole is a remarkably clever and painstaking example of the application of photography.

Reviewing as many of the more striking pictures in the West Room as our space will allow, the visitor on entering will probably admire A. H. Blake's "Blown Sand and Shadows" (4). This will have a lot of attention. It is unfortunate, however, that the sand gives rather the impression of snow, which is misleading. Dr. C. F. Grindrod's strong portrait of "A Cornish Fisherman" (5), just above this, we do not care for as much as some portraits from this worker. The expression is not pleasing, and the head seems somewhat too big for the frame. The application of bolting silk during the printing is not amiss in a picture so large in conception as this. F. J. Mortimer's "Majestic Main" (9) is a particularly large and open sea-scape, teeming with light and atmosphere, and, including as it does, a representation of the sun itself, may be regarded as successful in avoiding the appearing of a moonlight effect so often associated with sea pictures taken against the light.

At first sight Winthrop Somerville's "Scotch Moor" (20) strikes one as being a good thing, but a closer inspection reveals shockingly bad technical print. The printed-in clouds are so very obvious and much too heavy. They overlap the distant hills and are of a different colour to the landscape. The print also wants careful spotting in many places. T. Carter's "Rainy Day in the Moors" (24) is better, but here, again, the sky, although better managed, strikes us as coming forward too much. "Miss May Morris" (26), by "W. Smedley Aston," is a strong portrait of faultless technique, and very convincing. It is a well-arranged composition taken against the light from an open window, although there is also another subsidiary light from the opposite side. The brilliant pattern on the young lady's skirt is admirably broken, and, in consequence, is not too insistent. "Gossip" (29), by John H. Gash, is an example of this worker's now familiar treatment of out-door groups of Normandy market women and would be more successful if the figures were detached from the buildings at the back. They appear to be almost on the same plane as the foreground. "The Hour of Prayer, Tangier Mosque," by T. Ernest Waltham, depicts the arched entrance to a mosque, and has the most beautiful colour and lighting. This is seen to best advantage in daylight, but we are not sure that the value of the picture is not discounted by the colour of the canvas covered frame. "The Last Gleam," a large gum print, by J. C. Warburg, is a strong landscape in its way. It represents evening in a harvest field, and, viewed from a distance, great breadth is apparent. The composition is good, but the sky, representing as it does nightfall, appears to us to err somewhat on the light side, and its quality is rather poor. The suggestion of long shadows on the foreground stubble is very happy, the gleams of light coming between the wheat stacks, giving great luminosity to the otherwise heavy foreground. Furley Lewis's portrait of "Percy Lewis, Esq." (37), is admirable in every way, and no higher praise can be bestowed than to say it is worthy of Furley Lewis. It will be doubly interesting to the visitor to gaze on so striking a likeness of the winner of so many R.P.S. medals. B. Gay Wilkinson's landscape (41) is likely to also attract attention, as representing an idealisation of realism. It is as successful a rendering of evening light as we remember having seen. The sky is beautiful, and the foreground, although it appears very dark and blank at first, soon assumes its correct perspective, and the whole effect becomes very convincing. The important portrait on this wall of the late Lord Shand, by Wm. Crooke, is a strong piece of portraiture in Mr. Crooke's best and most vigorous style. We can suggest no improvement beyond a further suppression of the white stock. The concentration of light and modelling of the face in this splendid portrait will repay much careful study. As Mr. Crooke was one of the judges, all the examples of his powerful portraiture in the gallery are "not for competition." We really think that "not for competition" should also have been affixed by Percy Lewis to his two admirable Venetian pictures this year. Mr. Lewis can now well afford to rest on his laurels. No. 58, "Storm Swept," by J. Appleby, is somewhat dramatic, and the sky is much too heavy. The wind-swept sand dune in the foreground is, however, very fine. In "A Vegetable Shop" (73), Herbert Bairstow has given us a little gem. The quality of the work and the grouping of the figures are first class. The group is perhaps a trifle too central, but the whole is admirable.

Work from most of the best-known users of the camera appears on the walls, and these will be commented on in our next issue. The Invitation Section, the Scientific and Technical Section, and the Trade and Professional Exhibits will also be dealt with.

THE Photographic Department of the Acton and Chiswick Polytechnic will be opened on Monday, September 26, at Bath Road, Bedford Park, W. The lecturer will be Mr. Arthur G. Field, and the course of lectures with demonstrations will include:—The apparatus; the light, how to expose; how the lens does its work; the dry plate; standard method of development; when to stop development; all the new developers; intensification and reduction of negatives and prints; printing in silver, platinum, and bromide and chloro-bromide papers; carbon printing; vignetting, printing in skies and clouds; the studio; history of the development of studio lighting, modern methods of lighting the sitter; rapidity of the film the basis of the newer lightings; tips in portrait photography; daylight, electric, and other artificial light; backgrounds, accessories, posing; groups, indoor and outdoor; at home portraiture; copying and other work of a mechanical and exact character; press work; flashlight work; instantaneous work; developing films; landscape photography; architecture; orthochromatic work; lantern slides, etc.; principles of three-colour photography.

THE SALON.

FIRST NOTICE.

THE twelfth annual exhibition of the Photographic Salon, which was opened to the public on Friday last, September 26, is a triumph for the American school and the gum-bichromate process. The work and personalities of Mr. Steichen, Mr. Stieglitz, Mr. Coburn, and other Transatlantic enthusiasts so obviously pervades this clever little collection of bastardised outcomes of superfluous lenses and cameras, that one finds a difficulty at the first blush in believing that British photography and its leading exponents have now anything but a nodding acquaintance with that "new movement" which they so heroically initiated a dozen years ago.

Even Messrs. Hinton and Davison, the two most consistent and successful exhibitors in the little Piccadilly room, seem quite out of it on the present occasion—apparently having lost heart before the advance of the Great Army of "Gum Spodgers" (the phrase, be it remembered, is not ours), and content themselves with showing enlarged snapshots on photographic printing paper of a now quite conventional kind.

The majority of the exhibits, scarcely one of which, we frankly admit, lacks cleverness or interest, pay the handsomest tributes to the manipulative skill of their producers; but they can no more claim the title of photographs than can printed impressions from well-etched half-tone blocks. Your gum print at the Salon makes a magnificent pretence of being something which it is not—lithograph, wash or charcoal drawing, and in some instances oil and water colours. Conceding the liberty claimed in the revived forewords of the catalogue, "Why drag in"—photography? And should not these ingenious manifestations of revolt against the academic and conventional be seriously placed before the authorities of the New English Art Club with a view to their inclusion in the next exhibition of that body, which takes place in a few weeks' time. We make the General Committee of the Salon a present of the idea and trust it will be as highly appreciated as the other services which the Salon has from time to time acknowledged to this JOURNAL.

The effect of the selection by the American members of the Linked Ring, of the pictures submitted by American workers, is at once apparent after a glance at the catalogue, and has resulted, as we imagined it would, in nearly one-half of the entire Exhibition being composed of the efforts of a small body of workers in the United States, who cannot be called at all representative of American photography.

Dealing with the foreign efforts first as furnishing quite the most important and striking things in the show—although productions we are not in sympathy with—the work of Eduard J. Steichen calls for immediate attention. In this worker we have evidently a man who thinks and works out the results of his ideas with the object of causing thoughts in others. Just what these thoughts may prove to be is not always clear, but none can gainsay the originality of his methods and the power of his work. His portraits appeal to us as being distinctly stronger than his landscape productions.

Both the portrait of G. F. Watts and that of W. M. Chase are very fine indeed, the former tending perhaps a trifle to undue hardness, while the latter is seen to greatest advantage in an exceedingly strong light. In fact, all the exhibits by this worker should be seen in a much stronger light than that permitted at the Dudley Gallery. His landscapes have a curious elusive quality of their own, and we question their legitimacy in a photographic exhibition at all. No less than twelve frames are filled with his handiwork, and they will all repay close study as specimens of clever workmanship.

Alfred Stieglitz's two contributions are distinctly disappointing. We looked for far greater things from him than "The Flat Lawn" and "The Street."

Both Messrs. C. Yarnall Abbatt and Alvin Langdon Coburn appear to delight in dark and dirty tones that, although pressing a broad view of the subjects portrayed, have a morbid and somewhat unhealthy tendency. Of the former's work, "Cocktail" (199) is probably the most reasonable, although "The Bridge" (169) has qualities that are distinctly realistic and pictorial. "On Capri" (105) is hung rather too high for to appreciate much beyond the ragged mount. This fashion of mounting somewhat indifferent photographs on ragged-edged paper, with the intention, we presume, of increasing its artistic value, is attracting considerable attention, and is rapidly approaching the extremely narrow division which separates the possibly sublime from the obviously ridiculous. Many of the specimens exhibited at the present Salon may be said to have already passed that division.

Mr. Coburn's work does not wholly fascinate us, although we confess a liking for "The Bridge, Ipswich, U.S.A." (39), "Snow" (40). The latter, in particular, most nearly approaches being a good picture. It certainly most nearly approaches being a good photograph of all this exhibition's work. No. 36, "The Haunted House," bears out the tale and the weird resemblance of the house to a large face, possibly an assistance. "The Dragon" (151), an open landscape through which a winding stream twists and turns, has no great claims to pictorial merit beyond the delightful natural curves presented by the gleaming water.

Clarence H. White, whose efforts in previous Salons have caused a stir, appears to be marking time, and gives no evidence this year of increasing vitality. His eight exhibits are of very uneven quality, the most unsatisfactory of which appears to be "The Violin Player" (213). It is really asked too much from the imagination of the beholder to fill the blank in this specimen of "portraiture by suggestion." No. 99, "Sisters," is another specimen of the ridiculous method of mounting a photograph previously mentioned. In this case, in addition to the paper on which the print is fastened having uneven, ragged edges, it has further been crumpled up, rendered dirty, and otherwise maltreated until it has, we presume, become sufficiently mature to accommodate the mass of piece in posing and composition affixed to it. We should be pleased to learn exactly what added merit or charm this particular mount gives this particular picture. "The Cave" (107) fills no specific purpose beyond portraying a naked female aggressively peering around what appears to be a large tree trunk in search of her clothes. "Portrait" (17) is very satisfactory, with the exception of the signature of the author being placed in the middle of the print, while "In the Orchard" is perhaps Mr. White's best effort, the lighting being beautifully managed.

Mrs. Gertrude Käsebier is likewise a prolific exhibitor, eight pictures being on the whole better specimens of straightforward photography than much of the American work, erring very much indeed on the side of heavy murkiness, though this is in no way helped by the fact that the prints are mounted on large sheets of glaring white paper, entirely upsetting tone values and in some cases making the photographs appear but little better than black rectangular patches surrounded by an expanse of white mount. "The Road to Rome" (No. 34), a portrait of a lady nursing an apparently stuffed animal, is better, while "The Sketch" and "The Picture Book" (Nos. 165 and 166) are very fine indeed. Perhaps the last word of eccentricity as applied to a photographic production is supplied by No. 187, "The Koto Player," by H. G. French. It appears to have been produced or mounted on a piece of soiled and torn tissue paper of the species usually known as "curl paper." It is quite an achievement in its way, rivalled only by No. 192 near by, supplied by the same worker. To the effect, these two prints are further permitted to flap

the breeze caused by the visitor hurrying past. Whether the omission of glass from these frames is intentional or accidental we do not know.

Of the other American workers represented, J. T. Keiley has some half-dozen exhibits, none of which call for special mention. Mrs. Jeanne E. Bennett has only one, "Misty November Morning" (205). We can forgive the distance appearing altogether far more fuzzy than anything ever seen in nature, but cannot overlook this fuzziness in the near tree-trunks. They appear to have been X-rayed, and have a "bone" in them. Curtis Bell's contribution, entitled "The Last Load," is altogether beyond us. We give it up. The elucidation of this puzzle is not assisted by the somewhat dirty glass in the frame.

Miss Alice Boughton's "Water Sprites" is a rather weird, but nevertheless successful, photograph of two nude boys at a wooded bathing pool. J. G. Bullock's study in telegraph poles, entitled "The Beach," has its good points. It is small, and it is in the far corner of the room. Dr. F. Detlefsen's "Cameo Relief from Life" is not a very brilliant example of this sort of thing, nor is the object at which the young lady is gazing particularly clear. "The Navajo," by William B. Dyer, calls for no comment beyond that it is an exceedingly ugly male nude. J. Mitchell Elliott and A. A. Gleason have each fairly good snowscapes, but the same sort of thing has been done often before and much better; by Rudolf Eickemeyer in particular. "The Huckster" (16), by W. F. James, is unsatisfactory and a dirty colour, although the figure driving into a dust-storm conveys the idea of action well. "Rest at Nightfall" (216), by Frank E. Marks, is a rather heavy study of shipping, while "Carpenter's Hall, Phila.," by the same worker, is good, and mounted on what at first sight appears to be a piece of rag. Mrs. Jeanett Peabody's picture of a little girl with no boots on—"Caryl" (27)—is of too unpleasant a colour to be effective. "Youth" (128), by Miss Landon Rives, is good in composition and treatment, and quite excellent enough to have dispensed with the application of bolting silk to render it fuzzy. Harry C. Rubincam's portrait of a frightened boy (24), and Mrs. Sear's decorative portraits call for little comment, the latter's "Portrait of a Lady" being rather original in conception; but the string of beads with which she is bedecked is much too insistent. Also is it necessary to bind up in the frame a collection of bits of foreign matter to improve the appearance of the light mount?

On a future occasion the works of the Continental and English exhibitors at the Salon will be dealt with.

POLONIUM, the first radio-active substance discovered by M. and Mme. Curie, and so called after Poland, her native country. is distinguished from the other radio-active bodies, thorium, uranium, actinium, and radium, by the fact its radiation appears to consist solely of the alpha particles, which are larger, slower, and less penetrating than the beta particles, as well as not so much deviated by a magnet. Moreover, polonium does not yield a "gaseous emanation." Radium, as we know, emits both alpha and beta particles, and a gaseous emanation which contains helium. Two other radio-active substances have been found in pitchblende—namely, "radio-actinium" and "radio-active lead," but M. and Mme. Curie consider radio-tellurium identical with polonium. M. Debiere has investigated the matter, and come to the conclusion that there is no distinction between polonium, radio-active lead, and radio-tellurium. He also observed that while the radio-activity of polonium disappeared little by little, that of the nitrate of radio-active lead continued for several years. He, therefore, supposes that the constancy of radio-activity depends on external conditions, which it will be important to determine. It is possible that in certain conditions the activity of uranium, thorium, actinium, and radium may disappear like that of polonium.

OPTICAL NOTES.

[From the "Physical Review."]

I. REFLECTION AND REFRACTION AT THE INTERFACE OF TWO MEDIA HAVING INTERSECTING DISPERSION CURVES.

OCCASIONALLY there appear notices of methods for making objects invisible by selecting combinations of media having about the same index of refraction as the immersed solid. This subject was first investigated by Christiansen¹ in 1884. His object was to show that white powders are transparent. For this purpose he used a mixture of ground glass, benzene and carbondisulphide. The transmitted light varied in colour from violet to red, depending upon the size of the glass particles, upon the quantity of carbondisulphide mixed with the benzene, and also upon the temperature. That wave-length, for which there is an equality of the indices of refraction of the mixture, is transmitted without reflection or refraction. It varies with the temperature, is fairly homogeneous, and is called "Monochrome" by Christiansen. The reflected and refracted colours bear his name.

The most recent notice on this subject is by Wood,² who dissolved chloralhydrate in glycerine. This solution has almost

FIG. 1.

Dispersion curves: 1=benzaldehyde; 2=eugenol; 3=safrol; 4=methyl eugenol; 5=cuminol; 6=rock salt.

the same dispersion as glass, and finely powdered glass, in it, is transparent without showing a trace of Christiansen's colours.

The object of the present communication is to call attention to a phenomenon connected with media having intersecting dispersion curves, hence the same index of refraction for a certain wave-length of light.

While investigating the infra-red absorption spectrum of eugenol, $C_9H_{10}O_2$, it was found that the liquid had decomposed on standing exposed to the light, the colour having changed from a light to a deep reddish brown. As a film between two plates of rock salt, observed at a varying angle of almost grazing emergence of the light, one sees a brilliant series of spectral colours—reddish brown for the reflected, and violet for the transmitted rays. Safrol, $C_9H_{10}O_2$, which is light straw-colour, also shows this effect, while carvacrol, $C_{10}H_{16}O$, also straw-colour, does not. At first this seemed likely to be due to "Resonance." But the directly transmitted light showed no peculiarities as viewed in a direct-vision spectroscope. Furthermore, the same films between glass plates lost this property. It was then suggested by Professor Nichols that this is probably due to the near equality of the refractive indices of the two media.

¹ Christiansen, Ann. der Phys., 23, p. 198, 1884.

² Wood, "Phys. Rev.," Vol. XV., p. 123, 1902.

A glance at the dispersion curves³ of rock salt and the liquids, in Fig. 1, explains the question. In fact they contain more information than was first anticipated. In the region to the right of their intersection with the rock salt dispersion curve, the indices of refraction of the liquids are less than for rock salt, while to the left of their intersection they are greater. To the right of this intersection, as the rays pass from rock salt to the liquid, we have the ordinary case of total internal reflection, which can occur only when a ray, travelling in a given medium, falls upon the boundary separating it from a less refracting medium at an angle of incidence greater than the critical angle. To the left of the intersection, in the same manner, the rays pass from a less to a greater refracting medium, and we have the ordinary case of refraction.

However, the occurrence of total reflection, and of refraction at the boundary of two media, at the same time, by breaking up and dispersing a non-homogeneous ray of light is rather unique, and is so easily observed that it seems worth mentioning. It impresses us the more with the question of what occurs at the interface of two media, of optical density, etc., which will be considered presently.

Let us first consider what has really been observed when non-homogeneous light passes into a combination of media like a film of eugenol (from oil of cloves or benzaldehyde from bitter almond-oil; the essential oils might answer the purpose), held between the two plates of rock salt, as indicated in Fig. 2, where p , p = plates, s = the source of light, k = an opaque screen to prevent light from entering from below and thus confusing the resultant distribution of light. It was found,

Fig. 2.

on viewing the surface of the films of eugenol at an angle of almost grazing emergence, as shown in Fig. 2, that the totally reflected light was a reddish brown, which changed to a greenish yellow as the angle with the normal was increased. Viewed end on, a light green was visible. Moving the eye farther along so as to get the transmitted light, a quite deep blue appeared which changed to a blue-green, and finally light green as the eye was moved farther around the edge. For benzaldehyde, following in the same order, the reflected light was a deep red, cardinal, reddish brown to orange, then blue to green for the transmitted rays. In the same manner the colours for safrol were reddish brown, orange to light green for reflection, then violet, blue green to light green for the transmitted ray. Most interesting of all is cuminol, $C_{10}H_{16}O$, which, as will be noticed in the dispersion curves, Fig. 1, intersects the rock salt curve towards the violet. For this compound, the reflected rays, observed in the usual order, appeared in succession brownish red, yellow, green, and light green, while the transmitted rays were deep violet, then blue to deep green.

It is to be noticed that the arrangement of the spectral colours appears anomalous, i.e., red, yellow, green, then violet, blue, green.

However, since we are looking at the transmitted light we see the virtual spectrum, in which case the violet appears the least refracted.

A quotation from Rayleigh⁴ seems in order there, since the

³ Indices from Landolt & Börnstein. Physical Tables.

⁴ Rayleigh, Light, "Encyc. Britt." 9th ed., 34, p. 158, 1888. "The whole problem of reflexion is so much concerned with the condition of things at the interface of two media about which we know so little. . . . Reflexion depends entirely upon an approach to discontinuity in the properties of the medium. If the thickness of the transitional layer amounted to a few wave-lengths there would be no sensible reflexion at all. Our theories take no account of the fact that one at least of the media is dispersive. . . . We may thus expect a finite reflexion at the interface of two media if the dispersive powers are different even though the indices be absolutely the same for the waves under consideration, in which case there is no refraction."

media in question show continuity as well as discontinuity when we consider their dispersion curves. This combination might possibly be used to study the question of a finite reflexion at the interface of two media having different dispersive powers, at the point where the indices are the same.

The present cursory examination shows qualitatively how dependent the reflected wave-lengths are upon the relative difference in the refractive indices. Thus for benzaldehyde, where the intersection of the dispersion curves is towards the red, no green is reflected, while for cuminol all wave-lengths up to the deep green are reflected.

The experiment is simple and easily performed. Rock salt is easily obtained. The natural cleavage surfaces last the longest, and are usually just as plain as the hand-polished. The few striations will do no harm if the plates are put together at their common cleavage face. The splitting of the plates is most easily done by applying a thin, sharp-bladed knife, and tapping it gently with a light hammer. The size of the plates produced depends upon the dexterity of the manipulator as well as upon the homogeneity of the crystal. A plate 2 by 2 by .2 cm. will answer the purpose, unless a lantern projection is desired. A few drops of the liquid is placed on a plate, which is then covered with a second plate, and the two held together in a clamp or by means of a wire wrapped around them. The liquids mentioned have high boiling points, hence are convenient to manipulate. The incident light should not be too intense. Daylight has sometimes been found most serviceable. The bottom, one end, and the two sides of the lower plate should be protected from stray light. The incident light is then permitted to enter from above, and viewed from the other end, already described. Such plates will last for several months provided the surfaces have not been rubbed hard, nor scratched in cleaning.

The disappearance of an object when immersed in a medium having the same refractive index is less exactly shown by placing powdered rock salt in one of the liquids mentioned. (Ordinary salt will not behave thus.) A blue colour is visible for the transmitted light, while patches of totally reflected red are also apparent—"Christiansen colours." Applying heat, the whole becomes opaque, but again becomes transparent on cooling. For a lantern projection it is best to have the rock salt split into parallelepipeds having edges, say .5 to 1 cm. These are placed in a flat glass cell and covered with benzaldehyde. In this case the reflected and refracted rays (for light passing through the liquid) at the interface are just the reverse of the case already considered when the liquid was between the rock salt plates. Here we have violet, blue, green for reflection, then green, yellow, red for refraction, observed in the order already described.

At the same time that one observes this effect at the upper surface of the rock salt cube, the phenomena already described for a film of liquid between the plates can be seen at the lower surface if precaution has been taken to avoid stray light from entering the sides and the bottom of the cell. To demonstrate this most successfully it is best to have one large parallelepiped of rock salt in the liquid, covering its sides and the upper half of one end with tinfoil to avoid confusion from stray light. Even then it is difficult to repeat one's observations, and the method of placing the liquid between plates of rock salt seems preferable. However, for the spectacular, the display of colours from the parallelepipeds of rock salt in benzaldehyde rivals that obtained by interference of polarised light in thin mica plates. Rock salt is about the only transparent mineral from which such regular solids with plane, highly polished faces can be obtained cheaply. The effect is rendered still more conspicuous by placing ground rock salt in the bottom of the cell and the parallelepipeds above, thus projecting both upon the screen at the same time. As the cell grows warmer from the lantern the wave-lengths transmitted without reflection or refraction will shift in a very striking manner. W. W. COBLE

ON THE LOSS OF LIGHT BY REFLECTION AND ABSORPTION IN PHOTOGRAPHIC LENSES.

In the year we called attention to some researches by M. Cousin on this subject, and now Herr Martin, who is, we believe, one of the mathematicians attached to the Rathenower Optische Anstalt, so well known for many years as Busch, attacks the subject, and gives in this year's volume of Eder's "Jahrbuch" conclusions, which we summarise, and which, in the face of the increasing use of uncemented lenses, is of considerable interest to the photographic fraternity at large.

Herr Martin refers to Cousin's paper, and recalls his estimation of loss—40 to 60 per cent.—and states that this is so large that it is reasonable to doubt the correctness of the figures; further points out that the "effect" of a lens cannot be estimated as though it were a dynamo or steam-engine, because much depends on the colour of the light.

Limiting the inquiry to an axially parallel beam of violet light λ 415, the loss by reflection can be easily reckoned from the formula:

$$r_1 = \left(\frac{n_1 - 1}{n_1 + 1} \right)^2$$

which r_1 = the loss of a refracting surface with a refractive index of n_1 , when the incident light = 1. The residue of the light is obviously

$$1 - \left(\frac{n_1 - 1}{n_1 + 1} \right)^2 = \frac{4n_1}{(n_1 + 1)^2}$$

and, therefore, the loss by reflection from a second surface of refractive index n_2 is

$$r_2 = \left(\frac{n_2 - 1}{n_2 + 1} \right)^2 \cdot \frac{4n_1}{(n_1 + 1)^2}$$

neglecting the light which reaches the plate after repeated reflection from the surface of the lens, the amount of light which remains after the reflection from the second surface is

$$\begin{aligned} & \frac{4n_1}{(n_1 + 1)^2} - \frac{4n_1}{(n_1 + 1)^2} \cdot \left(\frac{n_2 - 1}{n_2 + 1} \right)^2 \\ &= \frac{4n_1}{(n_1 + 1)^2} \left\{ 1 - \left(\frac{n_2 - 1}{n_2 + 1} \right)^2 \right\} \\ &= \frac{4n_1}{(n_1 + 1)^2} \cdot \frac{4n_2}{(n_2 + 1)^2} \end{aligned}$$

the loss by reflection from one glass surface be calculated it will be found to be about 5 per cent., whilst at cemented surfaces is practically negligible.

In order to obtain a general comparison, the refractive index of all the glasses was assumed to be 1.58 for λ 415, and that there was no loss from the cemented surfaces, then reckoning the residue of light for x glass-air surfaces from

$$R = \left(\frac{4n}{(n + 1)^2} \right)^x$$

and for $n = 1.58$:—

$$R = \left(\frac{6.32}{6.66} \right)^x = 0.95x.$$

From this formula the following table was calculated:—

	Loss.	Efficiency.
	Per Cent.	Per Cent.
Single lens (2 glass-air surfaces).....	9.8	90.2
Double lens (4 glass-air surfaces).....	18.7	81.3
Triple lens (6 glass-air surfaces).....	26.7	73.3
Quadruple lens (8 glass-air surfaces).....	33.9	66.1

It will thus be seen that there is a difference of about 10 per cent. between each type.

If the absorption of light is taken into consideration, the above differences are considerably reduced.

According to Pfüger (Zeitsch. f. wiss. Phot. 1903, p. 141), the loss by absorption for λ 415 and 1 cm. of glass is for ordinary crown 1.8 per cent., for baryta crown 5.2 per cent., for baryta

flint 2.5-2.7 per cent. Herr Martin points out that these values were found by a thermopile, and therefore may not be absolutely accurate for the "actinic" rays.*

Now, considering that cemented objectives of five, six, eight, and ten lenses require much thicker masses of glass than the three or four thin uncemented lenses, the absorption must be greater; and if one considers that the loss of light from the surfaces cemented with yellow Canada balsam, with the three, four, six, and eight surfaces, cannot be neglected, then generally the uncemented lens system is only about 10 per cent. less effective than the cemented.

A Goerz double anastigmat Series III. F. 7.7 and a Busch Series III. F. 7.7 were compared, and both lenses being of 300 mm. focus, the following figures were obtained:—

I.

Goerz anastigmat F =	300	mm.
Loss by reflection, about	18.5	per cent.
Loss by absorption, about	14.1	per cent.
Total loss	32.6	per cent.
Efficiency	67.4	per cent.

II.

Busch anastigmat F. =	300	mm.
Loss by reflection, about	32.5	per cent.
Loss by absorption, about	4.7	per cent.
Total loss	37.2	per cent.
Efficiency	62.8	per cent.

Therefore, "efficiency" of the cemented anastigmat (I.) was only about 5 per cent. more than the uncemented anastigmat (II.).

MYCOLOGICAL PHOTOGRAPHY.

MUSHROOMS, toadstools, and other fungi are often so frail and inconspicuous that the world is apt to almost entirely ignore them. They are, however, so very important a feature in the vegetable kingdom that, as such, we cannot afford to let them die as nature often does, unpictured and unseen. The mushrooms and toadstools, as everyone knows, grow in meadows and pastures; some of the fungi on decaying trees; others on books and papers in damp places; more, again, on grasses and vegetables, which they destroy; and not a few on man, animals, and fish suffering with certain diseases.

John Boyd, in the current number of the "Photo Era," speaks at length of the photography of these fungi, and says: "I shall not here go into the microscopic varieties, but confine my remarks to some of those that come within the range of the ordinary camera; and it may be said, en passant, that we are assured there are over four thousand varieties that might be put under this head. The enthusiastic fungologist may appreciate the latter as a fact, but the most skilled camerist will not be likely to give the remark more than a passing thought—unless he wants a life task, and is ready to begin when he is yet in his 'teens.'

To the nature lover I would, however, point out some of the interesting developments that will open to him as he goes along, even when giving the subject only a casual study. There comes, first of all, a wealth of educational knowledge to be derived from the changes that take place in a fungus in a single night, and more if we choose to trace that particular species from its earliest

* Herr Martin appears to ignore the researches of Eder and Valenta on the absorption of colourless optical glasses, which proved that up to a 396 it was practically negligible, and also that the same experiments proved the absorption of Canada balsam in the visible spectrum to be negligible. *Trans.*

stage until it finally decays. Many of these changes are readily told by photography, but up to the present time no one has apparently had zeal enough to undertake their illustration. Only the mature specimens of a few of the best-known varieties have so far been impressed on the sensitive plate, and the figures we generally see are invariably the production of the artist in line and water-colours. This is not as it should be, and it can only be laid to the want of interest in the subject.

Let us for a moment look briefly at the growth of a mushroom, that we may better appreciate what we are going to perpetuate; and, in taking this single species, we can apply our remarks to the entire family.

A mushroom is a plant, and while so named, is entirely different from others of the vegetable kingdom, inasmuch as it does not possess chlorophyll, or the green colouring matter which is the chief characteristic of other vegetables, and therefore is incapable of converting inorganic into organic matter; hence it has to depend for its growth on the efforts of other plants. As it develops no flowers or seeds, its reproduction has to be accomplished by means of spores. These spores first assume the form of threads; these subsequently develop small round bodies, which grow larger until a stem is formed, when it finally forces the globular part above the surface of the ground. After this, the plants assume a variety of forms, such as cups, clubs, horns, cones, umbrellas, shells, faces, and spheres.

It is while passing through these phases that they can be followed day by day by the watchful and painstaking photographer, and their life histories told in a way the prose-writer cannot hope to impart it.

Owing to the wide habitat of the genus, we have to be on the lookout for specimens in all kinds of places, from the city pavement and damp cellar to the high tree-trunk of some forest monarch.

Mr. Boyd then describes various species of fungi and their peculiarities. He goes on to say: "We had now better leave the study of mycology and devote some time to the best means of photographing its various species. The tripod is such a particular part of our outfit that we should give it first place. For stumps, logs, and near the base of trees, our ordinary folding tripod will answer, providing it is rigid, and has sliding legs, as very often we have to set it up on uneven ground. For higher places we can raise the same tripod to almost any elevation by fastening three pieces of wood to the lower portion, but often this can be obviated if we have an attachment which fastens to the tripod head, and permits the camera to be elevated. In purchasing one of these, do not be deluded with any ball and socket contrivance which will not hold your camera firm when fully extended, and at right angles to the tripod. For the ground species we must resort to other means, as they have to be pictured at a low elevation. You can get good returns from making a miniature tripod about twelve inches in height, but the handiest and easiest prepared support is a piece of board 30 inches long, 6 inches wide, and $\frac{3}{4}$ inch thick, with several small holes bored along its length. To use it, you attach the camera to the board by your regular tripod screw at the most convenient hole, and elevate or raise the board with any handy thing, until you have it at the height you wish.

Any camera will answer, provided it has a good long draw of bellows, for it is needless to say we shall have to work very close to the object, though at times it may be found much more advisable to use the back combination of the lens, and take the picture from double the distance. This latter plan enables us to obtain better perspective drawing.

Of the plates to be used we have no doubt already satisfied ourselves that they must be orthochromatic, and those sensitive to the reds and yellows particularly are really what we need. A ray screen under certain conditions is also necessary, as we have violets and blues in some of our specimens, which

will call for special treatment. We have also seen how we have to deal with yellows of various tints, lilac, violet, greens, thus emphasising the use of colour-corrected plates. Back the plates with some good compound, unless you obtain the orthochromatics doubly coated, or already backed with a non-halation medium.

In picturing any of these fungi, whether they are growing on trees, logs, or on the ground, it is best to clear away extraneous objects from the field of view. I do not mean by this that you are to eliminate all traces of the surroundings as these are sometimes of as much value as the object you are picturing. To illustrate, suppose you have a Chanterelle at the base of a spruce tree; there is a lot of underbrush all around it, and, it may be, some forest plants also in the field of view. My idea is to remove such of these as give us, first, a complete view of the mushroom, then give of the remainder as detract from the primary object, leaving sufficient of the surroundings to show that the specimen grows in the thick woods, and that this particular one favours a spruce tree for its protector. Or again, we are portraying a Tricholoma. It is growing in a grassy place in the open woods; around it are the usual growths of ferns, wild flowers, and grasses. We should begin by clearing away all that is in front of it, and sufficiently back, to give it an individuality in the finished print, thus bringing its surroundings into view, but not in a dominant way.

In the foregoing I have spoken of giving an individuality to a specimen. This is accomplished in two ways, both of which should be worked in harmony. The first is to choose the proper lighting, and this is generally at right angles to the lens, slightly more to the front; the other is to use as large a stop as possible, and just sufficient to bring the principal object into good focus, and leave the balance of the surroundings to do for themselves, and at the same time assist the composition in an indefinite way.

If the work we are doing is to be doubly effective we should all our picturing to an adopted scale, so that in comparing specimens we can the more readily see the changes that take place day by day; and I know of no more interesting part of mycological photography than that which shows the abnormal changes in height and form which these plants undergo in a few hours. The term 'mushroom' growth is certainly no monomer, and the camera is the only means of actually proving the statement.

Of the exposures to be given, the developers and papers used, we might continue for pages and then not exhaust the information. Of the first, it is difficult to set up a rule that can be rigidly adhered to, because so many factors enter into it that do not confront the ordinary worker. The distance from the object, the confusing ground light, the colour of the specimens, and the size of the image are features that call for special reckoning, but for a starting-point one will be safe exposing from six to ten times that which would be given for group or portrait under similar light conditions.

Formulas for developers are everywhere, but the wise man usually adheres to that given by the maker of his plates. The latter has a big stake in your attaining the best results with his products, and you may be sure his chemist has experimented a great deal more than you will ever care to do, and knows what he recommends is what is best suited to the emulsion with which he has coated his plates.

Of the papers, the prince of all is carbon; though I must confess platinum for permanency and easy working is very suitable for black and sepia tones. Carbon tissues, however, can be had in colours to match so many of the species we meet, that if we choose to stand the extra work involved in the process we can certainly can produce gems of prints that are absolutely permanent."

AYLESFORD BRIDGE, KENT.

ERS of the picturesque and the beautiful, especially those who have intimate knowledge of Mid Kent (and, may we add, large numbers of photographers)—Eds. B.J.P.), will have heard with surprise and interest that designs for a new bridge, intended to replace the charming medieval structure which spans the Medway at Aylesford, near Maidstone, have already been accepted by the authorities. Unless (writes George Clinch in the "Times") some active measures of opposition are immediately taken it is to be feared that the ancient bridge, one of which are probably of the fifteenth century, will be entirely obliterated. Many of those who know Aylesford bridge and who are quite competent to form an opinion as to the necessities of the river navigation on one hand, and the traffic over the bridge on the other hand, believe that the removal of the existing bridge would be an unnecessary piece of destruction. They hold that a much more satisfactory scheme would be one which involved the making of a "cut" in the river for the purposes of navigation, and the strengthening of the old bridge by means of timber staging. The Society for the Protection of Ancient Buildings has, in fact, drawn up a scheme, which the following are the most important features. The new bridge in the river already mentioned would be commenced about 300 yds. above the bridge, and would run in a direction practically parallel with the line of railway. Over this cut, at a point nearly opposite the railway crossing, the new bridge would be built, with the existing bridge in continuation of it over the railway, thus superintending the dangerous level crossing. The road, approaching from the north, would commence to rise at the point where it joined that from the railway station, and would be carried on an embankment until it reached the railway, over which there would be a bridge in one span. The newly constructed channel or cut in the river would also be spanned by a bridge of one arch. The new raised roadway would be continued to the existing bridge, which might be widened for foot passenger traffic by means of timber staging. In this way the whole of the fine old bridge at Aylesford might be saved, whilst it would continue to be useful for future generations as it has for so many centuries already. As is well known, the Medway follows a beautifully irregular course, and the present bridge of Aylesford crosses it at the point where a rather sharp bend brings it near Aylesford Marsh. The proposed new channel, without in any way detracting from the picturesque character of this bend, would provide an almost straight reach, which would be of great value in assisting the passage of flood water, and, of course, would be a very great boon for the navigation of craft on the river. There are many other points in favour of this scheme, not the least being the possibility it would afford of an economically constructed bridge, because it is obvious that there would be no water to contend with, as the cut would be made before the new bridge was erected. But apart from considerations of sense, the loss of a picturesque structure like Aylesford bridge would be deplorable. Its old grey stones and its mediæval form entitle it to respect, and one feels very strongly that every scheme which offers the possibility of saving it should be carefully considered before it is adopted. The conservators of the river Medway and the other authorities concerned in this important question will have fulfilled their duties imperfectly if they do not give these schemes their fullest consideration.

DEPARTMENT STORE PHOTOGRAPHY.

DEPARTMENT store photography is not confined to America, and it tends to rouse the ire of German photographers as much as it does that of their American brethren. Like their American brethren, too, they, instead of trying to retain their trade by doing better than the others, attempted to enlist the Government into an appreciation of their grievance by asking the Minister of Commerce to make some kind of inquiry into the matter, but, of course, without success. The "American Amateur Photographer" observes that the State Association of German Photographers has determined to ascertain for itself what that it wanted to know, although with what object it would be hard to tell, and the following is the most important information obtained: Of the question sheets which were sent out to business houses, 49 with answers were returned from 18 towns, whilst of those sent to employees at the departments of stores 160 were returned answered. The 49 stores in question had in their photographic depart-

ments 309 employees, of whom 57 were operators, 85 retouchers, 63 printers, and 24 general assistants; 46 were employed as helpers, and there were 8 apprentices. The number of women engaged was 95. The average hours of work were 10, exclusive of breaks, and 8½, 9, and 9½ hours were only exceptional instances. The term of notice was generally a fortnight, and in only 10 to 12 cases was a month's notice usually given. Few fines were inflicted, and then only for lateness. The answer to the question, "How many portraits are taken daily?" was not answered with much exactness. As far as could be ascertained, about 735 portraits were taken daily in the 49 businesses, and the average for each would be 15. But the number of portraits taken in each studio is very different; for instance, one house in Berlin, on an average, takes 120 portraits daily, whilst in other small businesses only about 8 are taken. The minimum prices for cartes-de-visite and cabinets are 1s. 9d. to 1s. 11d. and 4s. 6d. to 4s. 9d. per dozen, respectively. The maximum prices vary considerably, and range from 6s. to 8s. for cartes-de-visites and 12s. to 18s. for cabinets. In a few establishments the receptionists are paid premiums for securing higher prices and large orders.

The average hours of work by assistants is nine, and the average salary said to be \$26.40 per month, but surely that must be to those boarding in the house. The closing sentence in the article from which we get the information is "This offers a splendid basis for further action"; but what action can be taken? The days of trade guilds are gone, never to return, and as has been already said in these "Words," photography is free, and always will be, "free for all."

FORTHCOMING EXHIBITIONS.

September 16 to November 5.—Photographic Salon, Dudley Gallery, Egyptian Hall, Piccadilly. Hon. Secretary, Reginald Craigie, Photographic Salon, 1904, Dudley Gallery, Piccadilly, London, W.

September 20-28.—Newbury Photographic Society. Hon. Secretary, E. J. Forster, Guildhall Club, Newbury.

September 22 to October 29.—Royal Photographic Society's Forty-ninth Exhibition; New Gallery, Regent Street, London. Secretary, A. W. W. Bartlett, 66, Russell Square, London, W.C.

September 29.—Beverly Photographic Society. Hon. Sec., T. J. Morley.

October 4.—Whitehaven Y.M.C.A. Zoar Photographic Exhibition. Hon. Sec., J. Hayward, 14, Albert Terrace, Whitehaven.

October 15-23.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

October 19-20.—Isle of Wight Photographic Society. Hon. Sec., J. Howard Burgess, 53, Pyle Street, Newport, I.W.

October 19-22.—Rotherham Photographic Society. Hon. Sec., H. C. Hemmingway, Tooker Road, Rotherham.

October 26-28.—Watford Camera Club. Hon. Sec., H. G. Trayfoot, 3, The Parade, Watford.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Barnbygate House, Newark.

November 2-23.—Plymouth. Hon. Sec. Photographic Section, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, 52, Frederick Street, Sunderland.

November 17-18.—Braintree and Bocking Camera Club. Hon. Sec. W. H. Tilston, 81, High Street, Braintree, Essex.

November 17-19.—Darwen Photographic Association. Hon. Sec., J. G. Thomas.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Honley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarnock Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubery, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 23-31.—Wishaw Photographic Association. Hon. Secretary, Robert Teffer, 138, Glasgow Road, Wishaw.

January 12-14, 1905. Boston Camera Club. Hon. Sec., H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500

for lantern slides and prints made with Barnet products. Elford and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
26.....	Ilford and District Photo. Soc.	Nomination of Officers, Appointment of Auditors. Open Night for the reading of papers submitted and not previously before the Association for the Henson Award.
27.....	London and Prov. Photo. Assoc.	Last day for sending in Prints "Holiday Competition."
30.....	Watford Photographic Society	Platinotype Printing for Beginners.
30.....	Wimbledon and Dis. C. Club	Mr. E. T. Holding.

CAPE TOWN PHOTOGRAPHIC SOCIETY.

THE annual general meeting of this society was held on August at the society's headquarters, Y.M.C.A. Buildings, Cape Town.

The acting secretary read the fourteenth annual report of society, and reported that the membership has risen from 156 November to over 200 in July. The event of the year has been Easter Exhibition, which was carried out on a scale never before attempted by any photographic society in South Africa, and shown a quality of work which easily surpassed all other attempts. The exhibition was opened by His Excellency the Governor, on Easter Monday, in the Government Art School; Queen Victoria Street kindly lent for that purpose by Dr. Muir, and remained open during the whole of Easter week. A striking feature of the exhibition the large collection of some of the best and most representative work from England, kindly loaned by the Royal Photographic Society, Great Britain, and the North Middlesex Photographic Society. competition was thrown open to societies outside South Africa, the result that pictures were received from Adelaide, Sydney, Boston and Philadelphia. In all 460 pictures were passed by the selection committee, of which 355 were from South African artists.

The society has this year been represented by two delegates at the Photographic Convention of the United Kingdom. They were Messrs. A. J. Fuller and J. P. Edwards. During the secretary's absence in England his duties have been carried on by Mr. G. Oakley. On looking over the amount of work successfully undertaken during the past year the society has much cause for congratulation, and the council feels that this achievement is largely due to the untiring zeal of their indefatigable secretary, Mr. A. J. Fuller.

The treasurer (Mr. E. C. Matson) presented to the members of society a most satisfactory balance sheet.

The election of office bearers for the coming year was then proceeded with, the following being elected: Patron, His Excellency the Governor, Sir Walter Hely-Hutchinson, G.C.M.G.; president, Sir David Gill, K.C.B., F.R.S.; vice-presidents, Mr. J. D. C. Wright, M.L.A., Rev. Wm. Forbes, Professor W. S. Logeman, E. Noaks; council, Messrs. J. P. Edwards, G. B. Kipps, E. Oakley, H. W. Schonegevel, F. M. Matson, J. A. Yallop, M. T. Quandt, and H. S. Jaeger; hon. lanternist, Mr. G. Ainslie; hon. treasurer, Mr. E. C. Matson; hon. secretary, Mr. A. J. Fuller.

A NEW Application of the X-rays. The latest aid to the identification of criminals in France is the X-rays. The head of the Radiographic Laboratory at the Salpêtrière Hospital, Paris, has collected 8,000 negatives of fractures and other internal and other outwardly invisible means of identification. The other hospitals of Paris probably contain twice as many more, and it has been suggested that these or similar records might be of the greatest utility, where indications fail to establish identity. It is even proposed that a system of preventive radiography should be enforced, every criminal being subjected to the X-rays as soon as arrested.

Commercial & Legal Intelligence

A RECEIVING order has been made in the matter of C. Lee, photographer, Bridge Street and Market Place, Heywood.

A WINDFALL for Creditors.—Good news for some Southport creditors is announced by the Liverpool Receiver. In 1886 the failure of Henry Sampson, a photographer of that town, with liabilities slightly over £2,000. Two dividends, amounting in all to 2s. in the pound were paid by the Official Receiver, and the matter rested there. Latterly the debtor benefited under the will of a relative, and he promptly deposited with the Official Receiver a sum sufficient to pay the remaining 18s. in the pound, with interest at 4 per cent. per annum for the period that has elapsed. The accumulated interest enables the creditors to receive not far short of 100 per cent. upon their debts.

A TRAVELLING Photographer in Trouble.—At the Borough Police Court, Oswestry, on Friday last, Albert Astley Hanlon, a travelling photographer, was charged by Mr. G. T. Belbin, photographer, Oswestry, with appropriating a case of photographs and two boxes of coupons to his own use. Prosecutor said on June 18 defendant came to his studio in Willow Street and asked for work as a photographer's assistant. He told him to call later, and he then engaged him as a canvasser for orders. He gave him a box of coupons and a case containing an enlargement of photographs, with instructions to canvass the town of Oswestry, and come back the same evening and report what business he had done. Since then defendant had not been in an appearance. He identified the case and the other things produced as his property, and valued them at £1 8s. P.C. Maddocks said he received a warrant for defendant's arrest on the previous day, and went to Shrewsbury, where he received him into custody from the Shrewsbury police. Superintendent Lewis said there were several similar cases pending against defendant in different towns in Wales. The Bench imposed a sentence of three weeks' hard labour.

ADVERTISING on the River.—H. P. Basset, a photographer, of High Street, Weybridge, was summoned last week at Staines, at the instance of the Thames Conservancy, for exhibiting an advertisement on a sailing punt, the same not being an advertisement or notice by the owner of such vessel having reference to his trade or business, contrary to the Thames Bye-laws, 1898, on August 13, at Shepperton. Mr. E. Glenshaw, who prosecuted for the Conservancy, stated that Bye-law 21 of the Thames Bye-laws of 1898 provided that no advertisement or advertising notice should be exhibited on any vessel in the river except that of the owner of the vessel, and which had reference to his trade or business. The expression "owner" in the Bye-law, under which proceedings were taken, was defined in the Bye-law as the "person whose name appears in the certificate of registration of such vessel." Defendant told the Court that he had been using the punt at Shepperton and Halliford Regatta, where he had been taking photographs. He had contravened the Bye-laws entirely in ignorance, but he had used the punt on other occasions in the river without being spoken to or cautioned by the Conservancy. The Chairman, to defendant: It appears from the Bye-law that all you have to do is to become the registered owner. Continuing, the Chairman added that he should be sorry to see the river become an advertising medium. Mr. J. C. Buckmaster: The advertising system is becoming a public nuisance in every direction. The summons was dismissed on defendant's paying the costs.

PHOTOGRAPHIC Industries, Limited.—After many weary weeks of stagnation in the company-promoting world a prospectus has at last appeared. The good news is brought from Ghent. Photographic Industries, Limited, is but a modest concern, in spite of its title. It proposes to acquire a certain freehold factory in Ghent, Belgium, and to carry on a photographic manufacturing business under the auspices of Dr. Findlay, whose patented and secret processes are also acquired. The factory, with appliances, is independently valued as a going concern at £13,350, and the purchase price for this and the processes is fixed at £28,500, of which £8,500 is payable in cash and £20,000 in Ordinary shares. These shares constitute the whole

of the ordinary capital, and the whole of the Preference shares, 30,000 of £1 each, are offered for subscription. They are entitled to a cumulative 7 per cent. and to one-third of the remaining profits after the Ordinary shares have received 7 per cent. The directors may proceed to allotment if £10,000 out of the £30,000 offered is subscribed, and the payment of an underwriting commission of 10 per cent. is authorised. The amount required to pay the 7 per cent. on the Preference shares is £2,100, and, though a chartered accountant estimates that this should be amply secured and more, the actual results of the past three years—during which, it is stated, the premises have been in course of construction and equipment—have amounted apparently to a profit of less than a thousand a year. Thus the affair seems distinctly speculative, depending entirely on development. One rather interesting item the prospectus contains is the statement that the company is in a good position in distributing its goods from the factory, as Ghent has the advantage over London of from 50 to 80 per cent. in carriage charges to such centres as Birmingham, Manchester, Liverpool, Leeds, and Glasgow.

RE Henry Carpenter, trading as Henry Carpenter and Co., 47, Orchard Street, Essex Road, Islington, and carrying on business at 14, Aldersgate Chambers, Goswell Road, E.C.—The public examination of this debtor came on for hearing at the London Bankruptcy Court on Tuesday last, before Mr. Registrar Giffard. The statement of affairs filed by the debtor disclosed unsecured liabilities amounting to £983 11s. 8d., and assets £9 12s. 10d., thus leaving a deficiency of £973 18s. 10d. It appeared that the bankrupt was a manufacturers' agent, and commenced business with a capital of about £300 of his own. His business was a failure from the start owing to a strike and to bad buying by his traveller, also to bad debts. In the beginning of 1903 he became acquainted with Joseph Bartnack, of 57, Crouch End Hill, and Bristol and Norwich, dealer in photographs, picture frames, etc. He told debtor that he was doing a large business in the provinces by taking orders from time to time for enlargements of photographs, in consideration of the owners giving orders for frames. He told debtor that his money was locked up in the business, and that he wanted more capital. He subsequently entered into a verbal arrangement with Bartnack, under which he agreed to find the money necessary for carrying on the business, in consideration of his receiving half-share of the profits. This arrangement continued down to the date of the receiving order. After a few months trading the shop at Crouch End Hill was closed, and the stock was removed to debtor's premises in Aldersgate, the London branch of the business being worked from there. All debts in connection with the business were incurred in Bartnack's name, and the business was carried on in his name only. As far as he knew no intimation was given to the creditors that he was a partner. One of Bartnack's creditors—viz., the British Art Co., of Essex Road, Islington—sued debtor for goods supplied to this business, but it was held by the Court that he was not liable. He put about £250 into that business and drew out about £50. When the execution was levied on his premises there were a large number of enlarged photos ready for framing, but they had not been paid for by their owners, or at all events the frames had not been paid for, as the owners generally paid for them by instalments. A deposit had been received in each case, and in many instances further instalments had been received. He had the names of the persons who had paid money in most cases, but in some cases he did not know the names of the customers, as they had a numbered card, and in those cases the number of the card only was entered in the books. He had not seen Bartnack for about three months, but he had heard that he had gone to South Africa. He carried on the business in the name of the Venus Art Studio Company, which style had been adopted prior to his joining the firm. He could not say whether that was the style of the firm in Bristol and Norwich. There was no banking account in respect of that business. Bartnack attended to the collectors in Bristol and Norwich. He used to go down and see them periodically. Neither debtor's name nor his address appeared on the order forms signed by the customers. He had not scheduled any of Bartnack's debts in his statement of affairs, as he did not think he was liable for them. Eventually, upon the application of the Official Receiver, the examination was ordered to be adjourned until November 11.

News and Notes.

A MEETING of the Liverpool branch of the P.P.A. will be held on Friday next, September 30.

TORBAY Camera Society held a meeting at Wellswood Hall, Torquay, on Wednesday last, when a lecture on "Competition for Photographers" was delivered by Mr. A. U. Searly, of Kingskerswell.

We are sorry to learn of the death of Mrs. Ashby, wife of Mr. J. T. Ashby, F.R.P.S., the well-known photographic writer and judge. Our sympathies are extended towards our bereaved friend and his family.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for current month has been awarded to Albert Haynes, Esq., London Road, Alderley Edge, for his negative, "Gamekeeper's Cottage."

THE Wimbledon and District Camera Club has moved into fresh quarters. The new address is The Rembrandt Studio, 6A, Hill Road, and the Hon. Secretary is J. Munro, Erskine Villa, 96, Richmond Road, Wimbledon, S.W.

BEARD'S Animated Photographs.—Mr. R. R. Beard, of 10, Trafalgar Road, Old Kent Road, London, S.E., sends us a little pamphlet which deals briefly with the subject of animated photography. The prices of exhibitions are included.

MR. E. A. LEBLANC, of the Photo Agence, 48, Avenue Montaigne (Champs Elysées), Paris, informs us that he has opened an office and dark room for the use of visitors, where all information can be had gratis. Plates and films may also be obtained for the Frena and Zambex cameras.

PLYMOUTH Photographic Society's Outing.—About thirty members of the Plymouth Photographic Society held an outing to the Cheesewring on Wednesday last. A visit was paid to the historic well and Church of St. Cleer. The weather was unfavourable for photographing, though it did not altogether mar the enjoyment of the visitors.

THE annual general meeting of the members of the Luton Camera Club was held at Franklin's Restaurant, Luton, on Monday evening last. The report presented by the secretary was a very satisfactory one, showing that considerable progress had been made during the past year, the membership having gone up from forty-five to about a hundred.

THE Boston Camera Club is holding an exhibition on January 12, 13, and 14, 1905, and the School of Art Rooms have been placed at the disposal of the club for the purpose, by the kindness of the School of Art committee. There will be open as well as club classes. Particulars and entry forms will be obtainable in due course from the hon. secretary, H. M. Hames, 65, West Street, Boston.

SOUTHAMPTON Camera Club.—On the 19th inst. the members of this club held their last meeting of the summer programme, when Mr. F. C. Wardell (representing Carl Zeiss) gave a very instructive lecture and demonstration entitled, "Some New Photographic Optical Instruments." We understand an attractive and instructive programme is about to be issued by this club for the winter months.

THE catalogue of the Royal Photographic Society's Exhibition at the New Gallery is a very fine production, and its production reflects unbounded credit on the Secretary, Mr. A. W. W. Bartlett. The half-tone illustrations are from blocks by The Meisenbach Co., Ltd., West Norwood, and the printing thereof by Harrison and Sons, printers in ordinary to His Majesty, St. Martin's Lane, London, W.C.

CRIPPLEGATE Photographic Society.—This society held their sixth annual general meeting on Monday, September 12, at Cripplegate Institute, Golden Lane, E.C., and we are glad to hear that excellent progress is still being made. The membership has increased so rapidly

of late that it has been found necessary to get increased accommodation, and henceforth the meetings will be held in one of the comfortable halls of the Institute. Mr. G. H. Depledge vacates the secretaryship, the duties being taken over by Mr. J. B. Parnham, 5, Reighton Road, Upper Clapton, N.E., who will be pleased to send particulars of membership to any gentlemen wishing to join.

THE Prospectus and Entry Form of the Sunderland Camera Club Third Annual Exhibition has been sent us. We note that there are six open classes, and that plaques specially designed by R. J. Bertram, of Newcastle-on-Tyne, are placed at the disposal of the judges, Rev. F. C. Lambert and F. M. Sutcliffe. The last day for entries is October 29, and full particulars are obtainable from the Hon. Sec., Selby Ord, 52, Frederick Street, Sunderland.

A NOVEL advertising scheme has been instituted by the "Daily Mirror." From time to time they will publish the photograph of a house, and if the tenant recognises the picture and applies to them they will forward a prize of two guineas. In the course of the next week or ten days the "Daily Mirror" photographers will be at work taking photographs of a number of houses in Romford, Chelmsford, Colchester, Southend, Clacton, and Ipswich. A score or more photographs will be taken in each town from which one will be selected at random.

THE First Photographic Portrait.—According to "T. A. T.," the first person to be photographed in England was the present Lord Avebury (Sir John Lubbock). Daguerre, it is stated, paid a visit to London to patent his invention, and on meeting Lord Avebury's father and explaining his new discovery, the youthful Lubbock was summoned into the garden and posed for the purpose of the first photographic demonstration. Unfortunately, there is no record of the exposure given. In the case of the first person photographed in America, Miss Dolly Draper, it is on record that half an hour's exposure was given. This portrait, which still survives, is a credit to the imperturbability of the lady, for she has managed to preserve an almost pleasant expression.

FORBIDDEN Photographs.—The German Government has prohibited the sales of the various photographs depicting scenes in connection with the betrothal of the Crown Prince and the Duchess Cecile of Mecklenburg-Schwerin, and there has been, in consequence, a great rush to secure them as curiosities and for speculative purposes. The photograph showing the newly-engaged couple receiving the congratulations of school children is particularly asked for, and the one in which the Crown Prince wears a weird Panama hat and clutches the Duchess's arm will doubtless be valuable in course of time. When the Kaiser was merely Prince William of Prussia the sale of similar photographs of like scenes was prohibited.

At the exhibition of the Thirty-third Congress of the German Photographic Union, the highest honour, viz., silver medal, was awarded to the photographic specialities of the Bayer Company, Limited, of 20, Booth Street, Mosley Street, Manchester. These included edinol, acetone sulphite, Bayer's flashlight, Bayer's fixing salt, Bayer's intensifier, Bayer's red varnish, Bayer's fixing-salt destroyer, Bayer's premier combination gold salts, Bayer's combined toning and fixing salt, and Bayer's gum, and also to their papers, viz., Pan, Tula, St. Luke's, Bromide, Aristo, Lactarine, and transfer paper. A number of artistic photographs on Pan paper were shown at the same exhibition, amongst which those by Oskar Trinkler, of Jena, also obtained high honours.

At the Private View of the Salon on Thursday of last week a large crowd of members and friends of the "Linked Ring" and other exhibitors were present, including H. Snowden Ward, A. Stieglitz, Alvin Langdon Coburn, Reginald Cragie (hon. sec.), J. C. S. Mumery, Hector Maclean, Frank Evans, A. W. W. Bartlett, Dr. Evershed, Miss Donaldson, Furley Lewis, R. Child Bayley, Thomas Bedding, P. R. Salmon, Miss Marion Silverston, Rev. F. C. Lambert, Ward Muir, F. J. Mortimer, Will Cadby, Mrs. Carine Cadby, George Scammel, A. Horsley Hinton, Mr. and Mrs. F. E. Mills, W. Benington, J. Packham, P. Wright, E. H. Carpenter, George Davison, M.

Southnot, Miss Constance Ellis, Miss Kate Smith, W. J. Clutterbuck, M. A. Cromack, Rev. E. G. Watts and Charles Moss.

The following are the awards in the recent exhibition of the Cambridge Camera Club, which appears to have been a completely successful venture:—Class I.—Architecture: Silver medal, Rev. H. R. Campion; bronze medal, Mr. T. J. Sowdon; highly commended, Mr. S. Orlebar; commended, Mr. S. J. Parson. Class II.—Portraiture: Figure Studies: Silver medal, Mrs. Addison; bronze medal, Mr. Johnso Smith; commended, Mr. A. S. Orlebar. Class III.—Landscape and Seascape: Silver medal, no award; bronze medal, Mr. C. Squires; highly commended, Miss Pope. Class IV.—No award. Class V.—Still Life and Flowers.—Bronze medal, Mr. W. Farren; highly commended, Mr. H. W. Chapman. Smith Challenge Cup: Mr. H. R. Campion. Class VI.—Lantern Slides: Medal, Mr. W. Green. Class VII.—Open: Gold medal, W. Claydon, Plymouth; silver medal, D. W. Kyle, Glasgow; bronze medal, S. G. Kimber, Southampton; highly commended, P. W. Crane, Heanoe; commended, G. Kimber, Southampton.

WARRINGTON Photographic Society.—The annual general meeting of this society was held at the Old Academy, Warrington, on Tuesday evening last. The secretary's report showed that the past season had been highly successful in every way, and the membership also showed satisfactory increase. The treasurer's balance-sheet was presented, the financial position being a balance on the year's working of £11s. 7½d. compared with a deficit the previous year of £8 6s. 5d. was resolved to ask Mr. Roger C. Parr to accept the office of president. The vice-presidents elected were:—Alderman Bennett, Messrs. E. J. Hall, J. Harding, F. V. L. Mahias, and W. Winstanley. Mr. Smithson was elected hon. sec. The following were elected for their respective offices:—Hon. treasurer, Mr. F. Garlick; hon. lanternist, Mr. H. Warburton; hon. assistant-lanternist, Mr. J. V. Moore; hon. auditor, Mr. P. Dalton. For the committee the following:—Messrs. F. W. Purse, G. Nicholls, D. S. Birrell, Mrs. C. Smithson, and Messrs. Bishop and Dolan.

MISSIONARY Cinematograph.—The cinematograph is to be employed by the Church Missionary Society in order to create further interest in this country in missionary work in India. According to the "Daily Chronicle" a skilled operator is leaving for a five months' tour in India, under the conductorship of a leading missionary. He will carry with him 10,000 feet of films and 250 photographic plates, which will be forwarded to England for development. Some of the results will be ready for exhibition in London next January, and afterwards the leading provincial towns. The scenes will be typical of life in India, and there will be no "staging" whatever. As showing the old India, and heathenism still has upon the people, pictures will be taken of Parsees worshipping the sun from the seashore in the early morning, and of Parsee funerals showing the vultures waiting to pounce down upon the bodies. Examples of native self-torture will be illustrated, as, for instance, a native hanging head downwards from a tree and swinging himself over a fire. Other pictures will show superstitious priests carrying brooms to sweep away insects from their path; children prostrating themselves before shrines; and multitudes bathing in the Ganges. By way of contrast all the leading features of missionary work will be depicted.

TRAINING for the Printing Craft.—The tenth session of the London County Council School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C., will commence on Monday, September 26. The school is open to those who are genuinely engaged in business in any branch of the photo-mechanical, photographic, designing, illustrating, lithographic, engraving, and printing crafts, and no provision whatever is made for amateurs. The courses of practical instruction are arranged to suit the following craftsmen:—Photo-engravers: Line and screen negative making, etching, proving, tricolour work; photo-lithography and preparation of originals for reproduction. Photo-lithographers: Negative making, photo-lithography, collotype (plate preparation, press and machine work), combinations of lithography and collotype. Photographers: Line and continuous tone negative making, printing, enlarging, transparency making. Lithographers: Lithography, map and plan drawing, transfer writing, drawing, design, lettering, photo-lithography. Designers: Design drawing, lithography. Draughtsmen: Drawing, design, lettering; pictorial com-

position. The school is well equipped with the necessary appliances for study and practical work. It contains large studios for life and elementary drawing, design rooms, lithographic studio, lithographic press room, photographic studio with electric light installation, dark rooms, collotype preparation, and printing room (with three presses), etching rooms, lecture rooms, etc. Only those engaged in the trade are admitted. The inclusive fees for the session are low. Trade apprentices, learners, and improvers (under twenty-one) are admitted free.

THE lantern lectures to be given in the North Room at the New Gallery, Regent Street, during the period of the R.P.S. Exhibition are as follows:—Thursday, September 22, the Affiliation Competition Slides, 1903 and 1904 sets; Saturday, September 24, "A Popular Talk on Colour Photography," with lantern illustrations, by T. K. Grant; Monday, September 26, "Lantern Views of Athens, its Monuments and Palaces," by A. L. Henderson; Thursday, September 29, "Cathedral Outlines and Sky Lines," by E. W. Harvey Piper; Saturday, October 1, "Photographic Studies of Marine Life," by F. Martin Duncan; Monday, October 3, "Submarine Boats, Past and Present" by Alan H. Burgoyne, F.R.G.S.; Thursday, October 6, "The Sculptures of Chartres Cathedral," by Ernest Marriage, F.R.P.S.; Saturday, October 8, Slides by Members of the North Middlesex Photographic Society; Monday, October 10, "A Popular Talk on Colour Photography" with lantern illustrations, by T. K. Grant; Thursday, October 13, "Marine Photography," by F. J. Mortimer; Saturday, October 15, "Morocco," by John H. Avery; Monday, October 17, "Camera Pictures from Balloons and Airships," by Miss Bacon; Thursday, October 20, "Northumbrian Rambles," by George Lamley, F.R.P.S.; Saturday, October 22, "Unfrequented Cities of Southern Italy, Ancona, Ascoli, Trani, Bari, Bitonto, Ruvo, Giovenazzo, Conza, Barletta, Foggia, Manfredonia, Troia, Milfi, Muro, Paestum, Salerno, Cetara, Capo d'Orso, Amalfi, Atrani, Ravello, Monastery of La Cava, Naples—Bronzes and Statuary in Museum—Pozzuoli, Benevento, Caserta, Caserta Vecchio, Capua, Sessa Aurunca, Savona, St. Gilles, Arles, Avignon," by J. Cooper Ashton; Monday, October 24, to be announced; Thursday, October 27, "A Popular Talk on Colour Photography," with lantern illustrations, by T. K. Grant; Saturday, October 29, "The Engadine and Lucerne," by Samuel J. Beckett, F.R.P.S. The lectures will commence at 8 p.m.

BATTERSEA Polytechnic.—The evening classes of this institution commence on September 26. Photography will be dealt with by Mr. E. Senior. The photographic department contains a large studio, fitted with Joel arc lamp and reflector, for photographic work at night; two commodious dark rooms lit with electric lanterns, and fitted up with every convenience for work. The equipment includes an 8½ by 8½ studio camera and lens, a 10 by 8-copying camera fitted with Zeiss lens, an electric light enlarging apparatus with 10 inch condenser, a complete set of carbon and platinotype printing apparatus, and a special camera for lantern slide making, so that ample provision exists for practical work. The classes are primarily intended for trade students, but others are admitted upon payment of higher fees. Students will be provided with necessary chemicals and apparatus free of cost, but must provide their own plates, sensitive paper, etc. Syllabus.—Elementary: Lectures on principles of photography; the camera and detached parts; the dark room and fittings; use of camera; plates; exposure; lenses; developers; defects; intensifiers, printing and toning; practical work in dark rooms and instruction in taking and copying with electric light. Advanced lectures: The studio; portraiture; lighting the model; use of screens; diffusers, etc.; the dark room; exposure; development; intensifying and reducing; the construction and use of photographic lenses; preparation and use of colour screens for isochromatic photography; shutters; orthochromatic and three-colour photography; photography in colours; cameras; landscapes; printing in silver, carbon, and platinum; printing in clouds, etc.; toning and fixing; retouching and spotting; elementary photographic chemistry; enlarging. Practical classes: Instruction will be given in negative making, contact printing on bromide paper, silver and platinum printing, general studio work, and lantern slide making; wet collodion process; single and double transfer carbon printing; artigue printing; and in the use of Dr. Albert's orthochromatic collodion emulsion. A special class in enlarging will be held on Tuesdays, 8.30 to 10.

INVITATION SITTINGS.

To the Editors.

Gentlemen,—I feel sure the consistent and moderately-expressed opposition of the JOURNAL to invitation work earns the grateful appreciation of the majority of professionals, who will also regret to see the reasonableness of your comments on this matter called in question.

Photographers who invite are at this moment doing their level best to score off those who will not, and no one can be blind to the irritation and distrust which is being engendered, not only in the Press, but among professionals themselves.

If copyright is only to be gained by this miserable, petty appeal to the cupidity of one's sitters, then the less we have of it the better for the business morality of photographers. It is over and over again made the excuse for mean and underhand attacks upon photographers of higher skill, by men who have neither faith in themselves nor respect for their work. These are the fellows who are damning the future of professional photography, who, both in high places among us and in low, are preaching the gospel of cowardice and "free sittings."

Apparently it requires more courage nowadays to ask payment for one's services than in the days gone by; it is also probably easier to learn the tricks of a lower commercialism than to master the difficulties of lighting and posing in the studio, and do business on an established reputation. But no one works on "free sitting" lines without exerting a decadent influence upon the future of professional photography, and your comments, gentlemen, are kindly directed against the common enemy.—Yours very truly,

T. C. TURNER.

Regent House, Hull,
September 18, 1904.

THE FUTURE OF PROFESSIONAL PHOTOGRAPHY.

To the Editors.

Gentlemen,—With your kind permission, I should like to state a few facts on the above subject. I fully endorse all your correspondent "Operator" says in your last issue, but he states the case too mildly when he insinuates that double dealing, meanness, and lack of business principles are to be found in the professional ranks; it is not only all this, but in some cases that have come to my notice the employers know practically nothing of photography or photographic processes themselves.

I do not wish to be a fault-finder, or I could mention several cases where specimens have been retained by the advertiser over a week, and then returned insufficiently packed, so that the prints were injured; but there is one case in particular I wish to bring to your notice. Specimens were sent with an application for the situation; within a week, as no reply was received, a letter followed, asking for the return of specimens; still no reply; two other letters were then sent at different dates, with a like result. Several weeks elapsed, when my friend the assistant happening to be in the town, called at the address and asked if they had received his specimens, and the repeated inquiries respecting the same. He was told that they had received something of the kind from some one, but they could not trouble to return specimens, and when asked why they did not write for stamps for return if they required them, he was told that the specimens were trash not worth the trouble of returning or writing about, and that he never would have had them if he had not called. I have not related half that passed at that interview; the gentleman in question was most insulting to my friend, and, respecting the specimens, they were infinitely better than any work I have ever seen in the window of this would-be employer.

Regarding the incompetent assistant. In many instances the

apprentice is kept to silver printing or some other equally elementary branch, wherein after a few weeks he is competent, over two of his three years apprenticeship (I am quoting facts). Of course, it saves the wages of a silver printer; but how is the apprentice to learn all he requires to know about plat, carbon and bromide printing, studio work, the making of negatives, retouching in nine or ten months? We know, in the words of the principal of one eminent firm, "the chief thing is to be grounded, one must have a good foundation," but in my opinion this is carrying things a little too far. It makes no difference a large and high-class firm how many incompetent assistants turn out; they know whom they have educated in things photographic, and they take good care not to employ them. After serving his time, the assistant is politely told they will give him 7s. a week as an improver, a sum they know he cannot possibly accept; therefore he is turned out into the professional world to be a nuisance to all photographers until he has gained sufficient knowledge to serve him at some good-middle-class business, or he takes a printer's place on a paltry 25s., unless there is an unusual amount of "grit" in him, when he will rise in the manner above stated there is no other way.

I could write of several circumstances with which I have personally been connected, but I will not intrude further on your valuable space, save to mention that there was, not many months since, a firm who were executing a "20 by 16 enlargement and cabinets, beautifully mounted and finished, for the ridiculous sum of 5s. 6d." They were, I was told, members of the Professional Photographers' Association. There is only one thing to be deduced from this; I hope it is clear to all my readers.

If I have unconsciously offered offence I ask those whom I have wronged to accept my sincere apologies. My intent is not to create discord but to show things in their true light, and to bring a state of harmony, if possible, between employer and employed.

Thanking you, gentlemen, in anticipation of insertion,—I am, yours sincerely,

ANOTHER OPERATOR.

September 19, 1904.

THE "STEADMAN" EXPOSURE SYSTEM.

To the Editors.

Gentlemen,—It seems from Mr. Steadman's letter that it is subject table "which is the new arrangement in the system," it is here, I am afraid, that Mr. Steadman has gone most wrong. Because Nature continually presents different types of subjects, the lens, it no more follows that each subject will require a different exposure (or diaphragm) than that it will require a different camera, a different lens, or a different developer. To quote an old long quip, it is not necessary that "who drives fat oxen should himself be fat."

If Mr. Steadman's text book is to be "acceptable to mathematicians and physicists," it must be based on up-to-date researches on light action on a plate, and these all tend to show that one type of exposure may be absolutely and scientifically correct for all types of Mr. Steadman's classifications of bird's-eye, middle distance, foreground, when represented on one plate, provided that the exposure is a good one with a long "correct exposure range."

The object of considering subject classification at all is simply to ensure that all the subject tones come within the range of tones which can be represented by the plate; and the greater latitude of the plate the wider becomes the group of subjects which may be included in one simple classification.

After all, the majority of photographs taken represent a group of subjects, which, if considered separately on the lines Mr. Steadman proposes, would require different exposures (or different diaphragms) and yet we know that when of necessity we give one exposure for all these varying subjects on the plate, that one exposure may prove correct for all.

If we follow out the idea that to attain accuracy different exposures are required for even slightly varying types of subjects, we shall arrive at the conclusion that each tone on the plate ought to receive a different lens exposure.

The fact is that we are still under the influence of the old exposure table subject classification, which the use of an actinometer would

have swept away. I did not shake myself quite clear of this
 in my earlier work, and Mr. Steadman is deep in it.—I am,
 yours, etc.,
 ALFRED WATKINS.
 Hereford, September 17, 1904.

ANIMATED PHOTOGRAPHY.

To the Editors.

Gentlemen,—Referring to the article "Revival of the Optical
 lantern" in your current week's issue, may I be allowed a small
 corner of your valuable space? Firstly, I join issue with your
 statement that the cinematograph has found its final place as a
 music hall edition of the daily papers. That it is capable of giving
 vivid representation of current events to thousands who could not
 possibly be present at the actual scenes goes without saying. The
 implied in your expression of "filling a turn at a theatre of
 varieties or a travelling fair temporarily located in a country hamlet"
 in my opinion, unworthy of a journal which devotes itself to
 photography.

Possibly one of the reasons why animated photography is so
 much more successful than the haphazard snap-shots of the ordinary
 photographer (from which, presumably, your lantern lecture slides
 are to be drawn) is due to the fact that the popular quarter-plate
 costs the nimble penny, and one penny more or less does not
 count much. But take the case of the man taking animated photog-
 raphs. He requires a most expensive plant and really expert
 assistants for producing his pictures, entirely apart from the actual
 cost of the material he uses (there are many cases that have come
 within my own knowledge where a picture has cost from £100 to £200
 to produce, and some special pictures have even cost five or six
 times as much as that), consequently more thought and care is
 expended over the production of these animated pictures than the
 ordinary photographer would dream of devoting to his most cherished
 productions. A smudge here, a smear there, and heigh, presto! you
 have an artistic production which will possibly be raved about
 because "it does not look a bit like a photograph."

But to return to my point as to the final resting-place of animated
 photography. Personally, I regard it as only in its infancy—there
 are possibilities in it from an educational point of view that are
 undreamed of. Take as an example a picture now showing at
 the Palace Theatre illustrating the production of steel. Here you
 have scenes in some steel works of which the ordinary man could
 have no conception unless he lived in the "Black Country." Again,
 there are many pictures being daily shown illustrating our different
 industries, from the launching of a huge ship on the one hand to
 the minor industries, such as hop-picking or strawberry-gathering.
 But the eye is an infinitely better medium for permanently im-
 pressing the brain than the ear there can be no two opinions about.
 Scenes and things that we saw years and years ago remain impressed
 on the brain long after the names of the places or things are
 forgotten; and teachers are more and more coming to use object
 lessons as the best method of impressing the youthful mind.

That animated photography suffers at present from its costliness
 and the risk attached to the use of such inflammable material as
 celluloid I willingly admit; but there are many minds and hands
 actively engaged in the endeavour to remedy both these defects,
 and when an unflammable film at a reasonable price is placed on
 the market there will be such a boom in living pictures that will
 eclipse anything that has preceded it in the annals of photography.

There is just one personal matter I should like to refer to, if you
 can spare me a little more space. As you are aware, although I
 was the pioneer of animated photography, at least in England, I
 have long since discontinued taking these pictures, contenting myself
 with the manufacture of the sensitive films on which others take the
 photographs; but I object to the Messrs. Lumière always being
 given credit for first showing these pictures in England. I photo-
 graphed and exhibited the Oxford and Cambridge boat race and the
 English Derby months before Messrs. Lumière published anything
 of their work, even in France, and a reference to the files of your
 own and other photographic papers will prove that the first animated
 photographs, as they are understood to-day, were taken by me and
 exhibited by me at the Royal Photographic Society, causing con-

siderable sensation at one of the meetings of that eminently staid
 society.—Apologising for the length of this communication, I am,
 yours faithfully,
 BIRT ACRES.

Whetstone Photographic Works, Whetstone, N.,
 September 19, 1904.

[At the conclusion of an article on Animated Photography in our
 Almanac for 1898 we wrote that it appeared to us this branch of
 photography was "destined to have something more than a transient
 existence, and that as an adjunct to the optical lantern, as a means of
 preserving records of scenes and occurrences, and for scientific and
 entertaining purposes we have only just commenced to tap its possi-
 bilities," so that Mr. Birt Acres and ourselves saw eye to eye on this
 point six years ago; and still do so. But, to be frank, we do not
 think, as the result of considerable observation, that the educational
 mission of the cinematograph excites much general interest. If it had
 to rely solely upon the depiction of industrial subjects it would at once
 pass into the realm of such scientific instruments as the microscope
 and the telescope. Mr. Birt Acres has not read our article aright.
 The "sneer" at the cinematograph was unintentional; will Mr. Acres
 deny that the variety theatre and the travelling show are the best
 customers for films? There can be no harm in stating a fact of this
 nature. We have not the slightest desire to deprecate animated photo-
 graphy; but we do wish to see the good lantern lecture revived, be-
 cause we think that the contemplation of a projected glass
 transparency accompanied by lucid oral comment and explanation a
 better method of impressing the brain than appealing to the eye alone.
 Which does Mr. Birt Acres prefer—"Hamlet" in dumb show—or
 acted and spoken by accomplished performers? There can, of course, be
 no doubt as to most people's choice. We are sorry our correspondent
 raises the priority question, and we do not decline the implied
 challenge. The Lumières showed animated photographs in Paris on
 July 11, 1895; Mr. Birt Acres's results were shown at the Royal
 Photographic Society on January 14, 1896. It is a small matter after
 all. Lumière's animated photographs were the first of the kind which
 we saw publicly exhibited in this country, and there surely can be no
 harm in our stating the fact.—EDS. B.J.P.]

THE GOLDSMITH INSTITUTE CAMERA CLUB.

To the Editors.

Gentlemen,—Mr. Downey, in his note announcing the demise of
 the Goldsmiths' Institute Camera Club, may give the impression
 that the technical classes for photography are also stopped; such is
 not the case, as the whole of the technical classes previously carried
 on by the Goldsmiths' Company are continued as before; the social
 side of the institute alone being suspended, with all the clubs belong-
 ing to that side.—Yours faithfully,
 NEMO.

Patent News.

THE following applications for patents were made between Septem-
 ber 5 and September 10, 1904:—

Mounting prints.—No. 19,097. "An improved method of mounting
 and protecting stamps, photographs, prints, and the like." Charles
 Ashby and Charles Egbert Ashby.

Developing apparatus.—No. 19,164. "Apparatus for introducing
 developing, washing, and fixing photographic plates, films, or
 sensitised surfaces without the use of a dark room." Hans
 Tirmann and Hugo Tirmann.

Dark slides.—No. 19,264. "Improvements in or relating to cassettes
 or dark slides for photographic cameras." Rudolph Krugener.

Shutters.—No. 19,380. "Improvements in photographic camera
 shutters." Julius Rudolph Hief.

Panoramic cameras.—No. 19,427. "Improvements in panoramic
 photographic cameras." John Boulton Brooks.

Cameras.—No. 19,511. "Improvements in photographic cameras for
 producing multiple photographs upon a photographic plate." William
 Tylar.

Changing device.—No. 19,570. "Changing device for photographic
 plates." Complete specification. Paul von Garainow-Trautten-
 berg and Max Leopold Fabian.

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

- J. Clapperton, 23, Albert Place, Galashiels. *Photograph of Celtic Font.*
 J. Harris, 56, Cromwell Road, Bishopstone, Bristol. *Photograph of the Bristol City Football Team, 1904-5.*
 J. Hargreaves, Union Street, Dalton-in-Furness. *Photograph of the late Rev. H. Hayman, D.D.*
 F. J. R. Macfadyen 151, Barras Bridge, Newcastle-on-Tyne. *Photograph of Figures in Reredos of Newcastle Cathedral.*
 P. M. Clark, Victoria Falls, Rhodesia. *Nine Photographs of Views of the Victoria Falls. Photograph of the Bend in the Gorge. Photograph taken amongst the Islands, Zambesi River. Photograph of a Boabab Tree. Photograph of Hippopotamus in the River Zambesi. Photograph entitled "In the Wash." Photograph of a Sylvan Scene. Photograph, Crossing the Gorge in Bucket. Photograph overlooking Palm Forest and Knife Edge.*

E. J. HEDGECOCK.—Probably "Dekko" paper, supplied by Kodak, Limited.

A. B.—We are sorry we cannot give you any information as to the firm named.

P. W. (Glasgow).—We presume you refer to paper negatives. Paper for the purpose may be obtained of any dealer. We do not undertake to answer letters by post.

JAMES WOOLLEY AND SONS and T. EVERITT INNES.—The preparation referred to is an American equivalent of the English Megilp, sold by all artists' colourman.

T. J. HANDS.—We did not retain the address of the writer, so cannot supply you with it. If you advertise what you desire to dispose of in our pages, the advertisement will most likely meet the eye of our correspondent.

M. D.—Messrs. Dawbarn and Ward, Farringdon Avenue, London, E.C., publish a book on various enamel processes. You might obtain the information therefrom. We do not undertake to answer letters by post.

SCRATCHED BURNISHER.—"Rex" says: "There are a number of scratches on the roller of my Globe enameller, which mark the prints when rolled through. Is there any means of removing the scratches?"—In reply: Only by polishing them out. We advise you to send the damaged roller to those who supplied the apparatus to do the needful for you.

ELECTRIC LIGHT.—J. H. VICARY says: "I am in want of a thoroughly up-to-date and reliable electric flash-light apparatus, capable of giving illumination to cover a good area, for large halls, etc. I believe it is against your rule to recommend any special make, but if you would kindly give me the addresses of any good makers I would esteem it a great favour."—In reply: Messrs. Adamson and Co., 24, Charles Street, Hatton Garden, make a speciality of electric lights for photographic purposes, but whether they have an "electric flash-light" we cannot say. Better call on them and see what they have.

COLLODIO-BROMIDE.—J. JOHNSON says: "I have lately been experimenting with collo-bromide emulsion, without success. The trouble is the bluish colour of the film when dried. Note enclosed scrap of ferrotype. This bluish colour only appears when plate is dried, and disappears on varnishing. I want to avoid this and to know cause thereof. 1. Has the pyroxiline

become denatured while emulsifying? 2. Is it insufficiently washed? 3. Or are the chemicals impure? Schering's and high temperature pyroxiline have been used separately and mixed with the same. It occurs when making an emulsion, and also when speeding it according to Hul Waterhouse. I may say that I am able to make gelatin emulsions of all kinds, but am new to collod. emulsion reply: The opalescence is in all probability due entirely the emulsion containing too much water, as we notice this is very crapy. Remedy: Use stronger solvents in future. The pyroxilines you have used are very suitable on emulsions.

UNREASONABLE CUSTOMER.—J. B. asks: "Will you please give your advice on the following, re the enclosed photograph shop? The proprietor engaged me to photograph his premises, instructing me to take up a particular position from which to take the photograph. This I did, and on presenting the proof he was quite nasty about the reflection on the window. He did not mind the reflection of a house on the opposite side of the road reflecting in his left-hand shop window complained most strongly of the way the two upstairs windows came out. I wish to ask if this is a reasonable complaint and whether I could have done anything to have avoided the result complained of, seeing that I was bound down practically one standpoint, and the few feet I could have moved away from that point to one side or the other did not make any difference? It was taken at 5.30 in the afternoon when the sun was not shining. If I take it again from the same position at any other time of the day there will probably be reflection somewhere, and he would not want to pay for a second time. I travelled five miles to do this job. If he refuses to refund should I have any chance of getting my money through court?"—In reply: Your customer is evidently a very unreasonable man. He bound you down to take the photograph from a particular standpoint, and left nothing to your merit. The photograph is, however, a very good one, and should advise you to sue for the money in the County Court and there is little doubt that you will obtain it, as there is no fault with the photograph.

SOUTH London Photographic Society.—At the last meeting W. T. Wilkinson gave a demonstration of "Photographic Methods of Illustration." He described the methods used in photographic printing, zinc etching, collotype, and photogravure processes, and said he found the best paper for photo-lithography is that made for final transfer in carbon work. As a substitute for making collotype plates he at one time used a mixture of soda and silicate of soda, but as all beers were not suitable, this necessitated visits to too many houses of refreshment. He was thus upon discovering some more satisfactory medium, and after a number of experiments has now adopted a solution of dextrine in place of the uncertain concoction known as "beer."

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

THE ALMANAC for 1905 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded.

* The frontispiece of the ALMANAC will consist of a portrait study specially taken by Mr. Furley Lewis (medallist of the Royal Photographic Society's Exhibition, 1903).

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc.

The publishers ask us to remind advertisers that a large proportion of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion, order and copy should reach them without delay.

**** IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that this year the entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1st next—a fortnight earlier than usual, so as to be well in advance of the Christmas publication season.

EX CATHEDRA.

A Suggestion for Plate Wrapping Paper.

A correspondent has made a suggestion which, whether it should prove of value or not, may well be put on record. Considerable attention has been given of late to the subject of the absorption of gases by charcoal, which is shown to be able to take up many times its own bulk of gas. Every one who has had much experience in the keeping of dry plates will have observed how much better some samples keep than others, but that eventually, after long years, perhaps, they succumb at the margins, an unpleasant iridescence making its appearance to the naked eye, while upon development the plate is worthless in the affected part. It will usually be seen that the giving way of the plate is a function rather of the wrapping than of the plate itself—the more securely the air is kept out the better it will keep. The suggestion we refer to is that if a maximum of protecting wrapping be first insured, the innermost wrapper might be a double paper containing a layer of charcoal, secured by some adhesive compound, and thus any small quantity of air that passed through the wrapper might be robbed of its injurious property.

* * *

Shellac Substitutes.

Shellac, the chief constituent of negative varnish, has greatly risen in price of late, and so a number of substitutes for it have come into the market. These are made to imitate both the brown and bleached shellac in colour and shape. The "Chemische Revue" of the resin industry describes some of them as consisting of resin, spirit-soluble copal, and other soluble resins in admixture with a little genuine shellac. Others are com-

posed of resin and fatty acids and fatty oils, or of resin and phenol. All contain up to 20 per cent. of water, and so furnish a dirty solution in spirit, besides necessitating a larger quantity of the "shellac" to give a varnish of a certain consistency. Makers of photographic varnishes should be further on their guard against these pernicious imitations of shellac, inasmuch as the resinous coating remains tacky for a long time, and can frequently be removed altogether with the finger. Also, certain of the substitutes differ from genuine shellac in being soluble in turpentine, a point of considerable importance when a retouching medium containing turps be applied to a negative which has been varnished with the solution of imitation shellac.

* * *

Mechanical Print Copying.

There is printed in "Machinery," over the signature of Joseph C. Riley, an ingenious and novel method of making a copy of a print or engraving of small dimensions. Though the method is not photographic—it, indeed, is antagonistic in interest to it—the method is so ingenious, and might, on occasion, be useful to any of our readers that we here transcribe the main points. Many who read this may remember the species of memorandum books which once were highly popular, though difficult to obtain now. They consisted of paper, covered with a smooth, chemically-prepared surface, which was written upon by a pencil, practically ever pointed, made of a compound like pewter, but which could be replaced by brass, copper, aluminium, or any of the softer metals. Mr. Riley has discovered that by placing a sheet of this paper on any small engraving or print, and then rubbing down with a hard smooth object, such as an ivory-handled pocket-knife, etc., the pressure so exerted, which partakes of the nature of a shearing stress, will cause sufficient of the black surface to give a distinct and useful copy, subject, of course, to the defect of being reversed. In his final instructions Mr. Riley finds it better to lay the metallic transfer paper face up upon at least a dozen sheets of blank paper, and lay the print face down upon it. Then place on the back of the print a piece of thin cardboard, and rub the tool over this protecting sheet. Slipping is thus comparatively easily prevented, and prints of eight or ten inches on a side may be copied satisfactorily.

Exhibited Photographs of Painters and Sculptors.

A morning contemporary points out that at the two annual exhibitions of photographs in London portraits of painters and sculptors are always fairly numerous, and this year is no exception to the rule. Last year Mr. Sargent was the favourite model; this year it is M. Rodin, the President of the International, two portraits of whom are at the Photographic Salon and one at the exhibition of the Royal Photographic Society. One of those at the Salon, proceeds the writer, shows M. Rodin seated in his studio before a bronze of "Le Penseur"—a bronze on the scale of the small original model from which, it is said, the huge figure shown last winter at the New Gallery was enlarged entirely by mechanical means. Unfortunately none of the Rodin photographs renders adequately the striking head and face of the famous sculptor. A portrait of another distinguished sculptor, less known in this country, is at the Royal Photographic Society's show, that of Reinhold Begas, the German artist who was proposed for an Honorary Foreign Academician at last January's election at Burlington House. The photograph is by Herr Hilsdorf, of Bingen, who is also responsible for the portrait of Adolph Menzel which hangs by the side of that of Begas. Menzel's

photograph is excellent, but a better impression of the greatest of German draughtsmen can be got from another portrait, also by Herr Hilsdorf, that hangs on the opposite side of the room. This second portrait shows Menzel—a quaint little figure in oddly old-fashioned clothes—standing in a room examining a sketch-book he holds in his hands.

* * *

Prices of American Work at the Salon.

Many a hard-working and clever professional photographer will gasp at the figures, so disproportionate to the value offered, when he ascertains the prices asked for some of the productions by Transatlantic members of the Linked Ring at the Exhibition now open at the Dudley Gallery. When he is informed that these specimens of photography are "works of art," imbued with the soul and personality of their authors, and not mere mechanical productions of the lens and camera, he will understand, and will probably thank his stars for having been blessed with a soul in a reasonably harmonious ratio to his intelligence. That the prices affixed to some of these specious examples of "modern photographic artistry" will cause many a visitor to stand amazed we are as sure as we are of the astounding fact that some of the pictures will find purchasers. Asking absurd prices varying from five to fifteen guineas for small smudgy prints, some of which are quite inexplicable, although we do not deny the cleverness of others, points only to one of two reasonable explanations. One is that prohibitive prices have been placed on these specimens of handiwork because their producers have no desire to part with their art treasures. The other is that they are the indication and outcome of life in a land of self-made millionaires, who individually may have sound judgment in most matters, but are apt to found their scale of appreciation in these matters on the scale of charges. We have no doubt that some of the buyers at the Salon who do not patronise home products (which we can assure them are as good as anything on view and much cheaper), but turn to these "personal reflections," only do so, impressed by the high prices demanded, and not from any real love of murky gloom and blurred representations of nature minus sunlight.

* * *

Sunburning Extraordinary.

If the report had originated in an American newspaper we should have passed it over as the product of an industrious imagination, but its appearance in a London morning journal, although it comes from an Irish source, gives it an importance which compels attention. The story told is exceedingly difficult to believe, but as name and place of occurrence are candidly stated, we have no alternative but to accept it provisionally. A gentleman who had been engaged in literary work, and had only been out of doors one day, when it happened to be dull and rainy, has suddenly, as the result of a dream, as he believes, been afflicted with all the symptoms of severe sunburn. If he had only dreamt that he dwelt in marble halls this deplorable thing would not have happened, but he was ill-advised enough to dream that he was lying on the sea-shore in a strange locality, and that the sun was shining upon him with all the intensity of noonday heat, so much so that he felt his face and hands actually being burned. "In my dream," he writes, "I remember thinking what a tanned face I would have after lying so long exposed to the glaring sun." When this strange vision of the night had passed away, and the dreamer arose to shave himself, he was astonished on looking in the mirror to find his face and neck literally

tanned dark brown, his nose in that peeling condition familiar to tourists, and his forehead so covered with freckles that any photographer would have been justified in charging extra for the retouching of a negative of his countenance. A doctor whom he consulted stated in the most positive manner that the patient must have been exposed for many hours to the sun, and when told that this was not the case, and the actual facts had been explained to him, expressed the belief that the force of imagination had, in the dream, tanned the skin and produced the freckles. The value of this story to the photographer lies, as Captain Cuttle would have said, "in the application of it." We cannot believe that this dreamer of dreams can be the only man who can set his imagination to work with such wonderful results. There must be many more who can do this thing if they could only be found, and we would suggest that a school for their training and general encouragement should at once be founded, and the tanned and freckled gentleman appointed to a prominent position on its staff. For does it not stand to reason that a man who can by the force of his imagination get such a marvellous imitation of sunshine would find no difficulty in printing photographs by the same agency? In comparison with what he has already done it would be the simplest thing in the world. A pile of negatives, interleaved with pieces of sensitive paper, would be put in his room when he went to bed, and he would dream that the sun was doing its beneficent work upon them. And while he was about it he might also dream that the prints were toned, fixed, washed, and mounted. Never, since the time of Joshua, did mortal man ever have such an opportunity to succeed as a photographer, and we trust that this worthy Irishman will be persuaded to instruct others in the useful art of dreaming things which come true.

* * *

Local Vandalism. In spite of the good work done by many societies, there are persons who never seem to be happy unless they are engaged in some scheme which involves the destruction of that which is picturesque or historically interesting. We are, of course, aware that in the natural march of progress many old things must give place to new, but there are certain beauty spots with which it seems sacrilege to meddle. How many of our readers, we inquired last week, have not at one time or other focussed upon the ground glass of their cameras that lovely picture of Aylesford Bridge, in Kent? There is no bridge like it for beauty within such easy reach of the metropolis. It is partly fifteenth century work, and its old grey stones and mediæval aspect should entitle it to respect even in this utilitarian age. But it is said to be condemned, and that designs for a new bridge have already been accepted by the authorities. We are not acquainted with the reasons for this decision, but we may suppose that the usual thing has happened. The old bridge is perhaps not strong enough or wide enough to accommodate the snorting traction engine, and it must be replaced by a hideous lattice-work girder abomination in steel. It is stated that the Society for the Protection of Ancient Buildings is interesting itself in the matter, and that it has proposed an alternative plan by which the old bridge will be left intact. We only hope that this effort to retain a beautiful piece of old work will succeed, and that all photographers who are friendly to the movement, as all must be, will do their best to strengthen the society's hands. But Aylesford Bridge is not the only relic of old times which requires protection just now. At a recent meeting of the Devonshire Association, held at Teignmouth, complaint was made of the wanton destruction of prehistoric remains on Dartmoor, chiefly by the authority of the Rural District Councils, with the laudable object of getting stones cheaply for mending the roads! And the

road contractors have already, it is said, removed a most interesting group of hut circles near Princetown. At the same meeting it was asserted that "one of the large stones of the Scorhill circle at Gidleigh, near Chagford, had been thrown down, and an attempt made, in the usual way, to split it lengthwise to make gate-posts of it." Now, what punishment ought to be meted out to men who are guilty of these enormities? They certainly ought to be locked up where they can do no more mischief, but the difficulty would be to find a prison large enough for their incarceration, for apparently these vandals are found all over the country. We may well conclude this note with an extract from the report of the Committee on Ancient Earthworks, dated July last:—"But that there is yet room for constant watchfulness of these relics and efforts for their preservation is plainly evidenced. Maiden Bower, one of the best-known earthworks of Bedfordshire, is in daily peril from the quarryman's pick; the fate of the curious work at Willington, almost certainly a Danish defence, on the banks of the Ouse, is trembling in the balance; and so it is with many another of these evidences of our country's story."

* * *

Forbidden Photographs. Whenever any Royal personage, or indeed any eminent person whatever, goes abroad, whether on business or pleasure bent, there are awaiting that illustrious one a host of camera bearers, or snap-shottists, as they are vulgarly called, eager to steal a pictorial record of the eminent one's appearance. Some persons would give their ears to be thus sought out by photographers, but the persons to whose lot it falls to be thus honoured are far from being pleased at the distinction thrust upon them, and we are continually reading that the American millionaire and his belongings are very sensitive on the subject of illicit portraiture. Such pictures of Royalties are sometimes of considerable value, for the reason that they are extremely difficult to get, and are, therefore, rare. Sometimes, too, a particular photographer may have the good luck to have a picture suppressed, and then of course it assumes a fictitious value, just as a book will under similar circumstances. We are not aware that official suppression of such a photograph has ever occurred in this country, but in Germany the sale of pictures illustrative of Royal doings has more than once been prohibited. For example, several pictures were taken which depicted scenes in connection with the betrothal of the Crown Prince and the Duchess Cecilie of Mecklenburg-Schwerin, and, as we noted last week, the sale of these has been forbidden. It is difficult to understand how a series of such photographs could be taken surreptitiously, and we can only suppose that the eminent persons chiefly concerned, after consenting to their production, repented of their action when they saw the results of the photographer's art, and had the pictures suppressed. Anyhow, we read that there is a great demand for the forbidden fruit in Berlin, and that the pictures are fetching fancy prices. One picture is in especial demand. It shows the newly-engaged couple receiving the congratulations of school children. Another which has also found favour with the curiosity hunters shows the Crown Prince in what is described as a weird Panama hat, clutching the Duchess's arm. Photographs of a similar kind taken when the Kaiser was merely Prince William of Prussia, were suppressed by the authorities, and these are now worth from fifteen to twenty pounds apiece. It would be interesting to know whether the fiat of the authorities goes as far as the destruction of the negative, but possibly the German photographers guard against such a regulation by the duplication of any negative which has the chance of falling under the official ban. We can all of us understand how Royalties, being only

human, should object to the wholesale distribution of photographs in which they do not appear to advantage. A case of the kind occurred not long ago when the Kaiser visited the Holy Land, and when many of the papers were comparing him to the old Crusaders. Some one took a snap-shot of the Kaiser during his journey, of which we saw a print. The German Emperor was in a uniform closely resembling that of our own Horseguards, and surrounded by a group of men so much taller than himself that he looked a mere pigmy by their side. We can well imagine that it would be consonant with the Royal wishes that such a picture should not get a post-card circulation. For every snap-shot of value there must be thousands taken which are not worth developing.

THE SALE OF SITTERS' NEGATIVES.

In "Ex Cathedra" a short time ago the question of the disposal of negatives was referred to as being a somewhat wide one as regards its legal aspect. Sometimes one sees advertisements for prints of portraits, or negatives, to be used as specimens in show cases, presumably by those who are themselves incompetent to produce work of their own good enough to attract customers. It is quite unnecessary to here go into the *morale* of a photographer exhibiting in his show cases portraits which he has purchased because he is unable himself to take such as would bring custom. The proceeding is little better than a fraud, as the public is naturally led to believe that the pictures shown are his own work, and that if they sit to him they will receive pictures equal to those shown, whereas they usually get those which are far inferior.

This, however, is not the question we are here dealing with. It is this. Has a photographer under any circumstances a right, legally, to deal with portraits, either as prints or negatives, that he has in the ordinary course of business been paid for taking? Let us take, by way of example, the sale of a business where the stock of negatives form a considerable part of the goodwill. In this case, perhaps, in the strict reading of the law as laid down in the Chancery Division of the High Court of Justice in 1888 by Mr. Justice North, in the case of *Pollard v. The Photographic Company*, the question is a little doubtful. But we imagine that in practice no difficulty will arise in this direction, as the purchaser will in his own interest respect his predecessor's sitters and negatives in the same way as he did, so that here no question at all is likely to arise. Therefore this part of the question may be dismissed.

There are, however, other ways in which negatives may change hands that may lead to the annoyance of sitters and possibly to legal proceedings. Take, by way of example, a photographer becoming bankrupt. In such a case the Official Receiver, or trustee, may have to realise the debtor's assets in the best way he can for the benefit of the creditors. This is often done by selling the effects, negatives included, at auction. Here the negatives, and probably a number of prints, have passed out of the photographer's hands, not voluntarily, but compulsorily, and according to law, as it were. He certainly cannot be proceeded against, as he has not disposed of the negatives or used them for any purpose of his own, nor has he sold them.

A few years ago we saw, at the Islington Friday Market, for sale a number of fine carbon enlargements of large size,

framed, of well-known persons, and also a large number of portrait negatives, which were very fine work. They all bore the photographer's register numbers and the names of the sitters, and several, we noticed, were titled people whose portraits had been taken in the ordinary course of business. We recognised that the pictures were the production of a West-end concern that had "come to grief." What ultimately became of the negatives we are unable to say, but they were offered to us as we were looking at them for a quite nominal sum—not much more than the boxes that contained them must have cost. Now, the question is had the purchaser of these negatives the right to print copies from them and sell them, or even to exhibit them publicly? That is rather a knotty point. One can readily imagine the annoyance of aristocratic personages who have paid high prices for their portraits—and the concern that produced those referred to commanded very high ones—knowing that their portraits were being exhibited in the showcases of third or fourth rate photographers in perhaps the East-end of London. On the other hand, the purchasers of the negatives would not altogether unnaturally think they had a perfect right to do as they liked with their own and this raises another somewhat interesting point.

Can the originals prevent the exhibition or sale of their portraits in the above circumstances? We opine that they can. The copyright in a portrait is vested in the sitter if the photographer has been paid for taking it, but he or she can take no action until the copyright has been registered at Stationers' Hall. Now if the person whose portrait is being so dealt with registers the copyright in it, he can restrain by injunction the sale or exhibition of it from the time of registration, but can do nothing with regard to what has been done before. Clause 6 of the Copyright Act makes it an offence "to multiply for sale, hire, *exhibition* (the italics are ours), or distribution" any copyright work, and renders the offender liable to a penalty of £10 for every copy, forfeiture, injunction, damages, etc. From this it will be seen that anyone who has purchased negatives, even under circumstances such as those just referred to, can be restrained from making any use of them if the sitter elects to register his copyright in the picture. In registering the copyright it should be registered in the name of the sitter, adding that of the photographer as the producer.

The note in "Ex Cathedra" referred to at the beginning of this article arose from a query that was replied to in the "Answers" column a little while before, in which a correspondent asked the best way to dispose of old negatives, presumably by sale, which, it is pretty clear, is illegal if the photographer was paid for taking the portraits, and might get the seller into trouble. The best way of getting rid of many old negatives is to scratch the faces and then get the dustman for a trifle to take them away, for the value of the glass now is practically nil. It was different in the wet collodion days; then the negatives could be cleaned off and the glass used again.

There is another way in which they may sometimes be profitably disposed of, namely, that adopted by M. Camille Silvy when he retired from business after the *carte-de-visite* furore subsided. Silvy, it may be mentioned, took eight negatives on a plate with four lenses and a repeating back camera. When he retired from business he advertised that his sitters could purchase their negatives, from which any photographer could produce copies, for the sum of, we believe, half a guinea. In this way he realised a substantial sum, and sitters became the possessors of their negatives.

EXPOSURE AND DENSITY.

SOME slight signs having been evident during the present year of a revival of interest in the theoretical and scientific aspects of photography, it may be a fit time to write a few notes regarding a theory of the relation between exposure and density in dry plate negatives which I advanced some years ago in the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY. Messrs. Hurter and Driffield gave, in their original paper, a formula for the expression of the density due to a given exposure which would be undeniably correct if the bases upon which they worked could be granted; but, unfortunately, in several respects these bases are not at all in accordance with the conditions which exist in actual practice; hence the value of the formula is at least doubtful, and it still seems desirable that the subject should be examined with strict consideration of all the facts actually existing in photographic work.

The following are conditions which I think may fairly be considered as applying in dry plate photography—viz., the sensitive salt consists of grains of appreciable size contained in a film of a certain thickness. The sensitive salt is of varying degrees of sensitiveness. On exposing any particular particle of it to light for time and intensity equal to its specific inertia, the particle will become changed and arrive at the developable state. On a further much prolonged but definite exposure it will again become undevelopable owing to reverse action. (I shall not deal, however, with that subject in this article.) Supposing, then, these statements to be granted, and assuming also (although it is open to question whether it is an entirely correct assertion) that, after complete development, the whole of the changed particles will be reduced and no others, let us now consider the effect of the exposure of a plate for a suitable time on a subject containing a long range of intensities of light.

In the first place let us imagine a plate in which the sensitiveness of the silver salt does not vary, but every particle has an inertia of a constant value. Evidently, in that case, in all the parts of the subject where the intensities are of less value than the inertia, they will produce no developable effect, and when they are just equal to it they will change only the Ag. Br. which lies quite at the surface of the film. Those intensities which are greater than these will, in penetrating the film, be of course diminished by its opacity, and to an ever-increasing extent according to the depth reached, so that each at some definite level will be brought to just equal the inertia. Beneath that position the light passing will be still less intense and consequently cannot render any of the Ag. Br. developable, while in all the part above the intensity will always be greater than the inertia value, so that the whole of the sensitive salt therein will be changed. It follows from this that the transparency of the developable silver will always be exactly in the inverse ratio of the original intensity to the inertia intensity. Light of threefold intensity, for instance, in being reduced to unit intensity must pass through a medium having a transparency of one-third. Hence it seems clear that the ratio of gradation of the transparencies of the changed silver over the plate will exactly correspond, inversely, to the various intensities of the subject in the case of all intensities lying between that of the inertia and that producing the maximum of density. If it were possible to employ a developer which merely rendered the altered Ag. Br. insoluble in the fixing bath without changing its colour, we could in that manner obtain, for all subjects whose range of gradations did not

extend beyond the limits indicated, the ideal "correct negative" of Messrs. Hurter and Driffield. But the "periods of under and over exposure" on such a plate would be absolutely devoid of gradation, the former showing nothing but bare glass, the latter a perfectly even density.

It will, I think, be difficult to find any flaw in the above reasoning, but, if it be accepted as sound, a result will be that the Hurter and Driffield "Correct Formula" falls entirely to the ground. That formula starts also with the assumption of equal sensitiveness in every particle of the silver salt, and leaves the matter of reversal out of consideration, but arrives at very different results.

I have assumed, however, that, as a matter of fact, the sensitiveness does vary—an opinion in which I believe most will agree. Let us now suppose, then, that our plate contains particles of Ag. Br. of many grades of sensitiveness, and examine successively the effects resulting from the action of light upon it in a series of increasing intensities. An exposure equal to the inertia of the most rapid grade will produce the beginning of a developable effect and greater intensities will form in the silver of that grade an image which has densities rightly corresponding to their gradations; but, as we follow the series, there also come into action at every step particles having higher inertias than those previously concerned, and add their densities to the total sum, which consequently is always greater than what would result from a continuance of the progress in the grades which have already been acted upon, so that the gradations of densities of the changed silver, plotted graphically, will take the form of a curve concave towards the starting point. When that intensity is reached which measures the inertia of the slowest grade of Ag. Br. in the plate, a certain definite quantity of the sensitive salt will have been rendered developable. Let us put that intensity as equal to γ , and the density produced by it as equal to γ . Now, from that stage onward, we shall have conditions similar to those of the case previously considered, for it is evident that from the surface down to a level where intensity is reduced to a certain value (i.e., to β), the whole of the Ag. Br. in every instance will be made developable; but below that the intensity of β will still produce an additional density equal to γ . Consequently, it must follow that, for intensities greater than β , we shall again have the conditions of the "perfect negative," as the even additional deposit of γ density in no way affects the truth of the gradations. Graphically, we shall have a perfectly straight line. Such conditions will continue to exist, as density increases, till on approaching the maximum the amount of unchanged Ag. Br. begins to fall short, and then those portions of it included in each of the different grades will consecutively become exhausted, according to their various degrees of sensitiveness. The density here, therefore, must always be less than would have arisen from a continuation of previous conditions, and the line will show a flexure in the opposite direction to that of the commencement, always increasing till maximum density is reached.

It appears to me that the foregoing is a reasonable way of considering the subject of exposure and density. Stated shortly, it may be put: "The gradations of a negative, if rightly exposed and developed, represent the varying degrees of transparency which, during exposure, have reduced all the intensities of light in the image to one common intensity; consequently, their transparencies are inversely proportional to those original intensities."

The conclusions arrived at are perfectly in harmony with the teaching of Messrs. Hurter and Driffield's experiments and with most of the practical applications of their principles, although somewhat opposed to the latter on the theoretical side. There are several points which it might be interesting to consider, but I will not at present occupy space in touching upon them.

H. J. CHANNON.

A COLOUR-SENSITIVE COLLODION EMULSION.

[Translated from Eder's "Jahrbuch," 1904.]

COLLODION emulsions with an excess of bromide, which are generally used at present, do not lend themselves to the addition of most of the dye stuffs for colour sensitising in a sufficient degree for practical work, unless in the presence of some soluble silver salt. Solutions of the silver salts of eosine are, therefore, used, or the plate, coated with stained emulsion, is dipped in a weak solution of silver nitrate before exposure.

This process, however, has the disadvantage that the emulsion, in the presence of soluble silver salts, soon becomes unusable, and one often has to contend with fog in development. The film is also extremely sensitive to impurities.

The favourable influence of a soluble silver salt upon the action of the dye stuff should be traceable to the elimination from the emulsion of the residuum of the bromide salt, which adheres to the particles of silver bromide, and prevents the precipitation of the dye stuff. A high degree of colour sensitiveness may also be attained without resorting to a silver salt when the emulsion is prepared with an excess of silver. The same may be said of emulsions that contain a little chloride of silver, and in which consequently only soluble chloride can be present.

Based upon various experiences in the preparation of emulsions, we used ammonio-silver oxide to make an emulsion which should be of the greatest possible sensitiveness and contain chloride of silver. The result was in every respect satisfactory. In this process, although considerable quantities of silver chloride remain in solution of ammonia, and pass into the washing water, the emulsion works without a fault, and clearer negatives are obtained than those which are prepared with preventatives of fog, such as aqua regia. The sensitiveness, moreover, is at least twice that of a collodio-iodide plate.

For preparation of the emulsion the following solutions should first be made:—

A. 50 grammes of silver nitrate are dissolved in 50 c.c. of ammonia, after which 100 c.c. of alcohol (strength 90 per cent.) are added.

B. 27 grammes of bromide of ammonium are dissolved in 40 c.c. of water by heat, then are added 100 c.c. of alcohol and 15 c.c. of an alcoholic solution of lithium chloride.

The silver solution is added to 700 c.c. of 4 per cent. collodion, and the hot solution of bromide added little by little. A very fine grained emulsion is thus obtained, which is red by transmitted light. After letting it stand for a few hours it is precipitated in water, and redissolved in alcohol and ether.

Stirring the emulsion before precipitation does not increase its sensitiveness, and as there is no bromide present, it does not cause any change in the size of the grain of the silver bromide, although ammonia be present. However, the emulsion becomes more liquid, which facilitates the coating of large plates. The emulsion, as we have already mentioned, permits of all dye stuffs used for colour-sensitising exerting their full strength, provided otherwise favourable conditions exist for dyeing the bromide of silver. In this respect special care should be taken that the emulsion of silver bromide be treated with the aqueous solution of the dye stuff. Consequently, it is necessary that the plate coated with unstained emulsion be bathed in such an aqueous solution of the dye, or that an alcoholic solution of the dye be added to the emulsion, and the plate afterwards washed. Eosine, rhodamine, ethyl-violet, and many of the recently prepared chinaldin-cyanines, as, for example, Dr. E. König's p-Tolu-chinaldin-chinolinmethyl-cyanin iodide, have been found specially suitable dyes, which do not produce fog in development. The last named, a purple-red dye stuff, which hitherto has not been found of any practical use, is a splendid sensitiser for green. Like Orthochrom T, used with a gelatine plate, it yields an almost continuous spectrum from orange to the colour for which the collodion plate itself is sensitive.

Each of the dye stuffs we have named imparts to the emulsion a colour sensitiveness exceeding the blue, and a mixture of the last named green sensitiser with ethyl-violet enables one to produce a panchromatic plate, the sensitiveness of which is four or five times as great as that of wet silver iodide.

BARON A. VON HUBB.

THE CHEMICAL REACTIONS WHICH TAKE PLACE IN TONING AND FIXING WITH THE SALTS OF LEAD.

[Translated from Eder's "Jahrbuch," 1904.]

THE action of the salts of lead in baths for toning and fixing has been the subject of numerous investigations. Recently Messrs. Lumière and Seyewetz, after a long series of experiments, have arrived at the conclusion that the toned print contains no trace of lead.

On the other hand, in analysing paper prints toned with lead salts, I have found traces of such salts, my procedure being different from that of the authors I have named. I treated the ashes of the paper with boiling hydrochloric acid, and, as the lead is converted to chloride, it is easy then to detect it.

Messrs. Lumière ascribe the action of the lead salts to the so-called sulphur toning of the image. But even if it be granted that only sulphide of silver is formed, it is incomprehensible how any bath that only sulphurises can produce the black tone one obtains with the salts of lead. Neither the mixture of alum and hyposulphite, nor the pentathionic acid, which the said authors found possessed of a specially energetic sulphurising action, will account for it. The said authors only used the pentathionate of lead to make a good toning and fixing bath.

This fact, and the additional one that the toned image always contains lead, although it may be in many cases only small in quantity and difficult to trace, confirm that which I established many years ago, that the toning is set up especially by the lead sulphate.

It remained to be explained how this sulphate of lead could be deposited upon the image, and this explanation has been the object of my recent researches. I am now in position to present a theory, which appears to be highly probable.

It is known that a mixture of a lead salt and hyposulphite of soda yields a precipitate of sulphide of silver. This comes about because the hyposulphite of lead formed in the mixture is the result of slow decomposition, according to the following formula:—

Scarcely has the anhydrous sulphuric acid been liberated before it acts upon the hyposulphite of soda, and produces the following change:—

Consequently, a deposit of sulphur is formed at the same time as that of silver sulphide, and a liberation of anhydrous sulphuric acid takes place.

But when the silver image comes into contact with the bath, the strong tendency of silver to unite with sulphur facilitates both reactions referred to, which may be regarded as one, and the final reaction, when in contact with the silver forming the image, may be stated as:—

If the bath also contains chloride of gold the presence of the lead salt facilitates the precipitation of the gold, and I conclude that the presence of the sulphate of lead very likely favours the formation of gold sulphide on the image.

The sulphide of gold may add much to the blackness of the image. In any case, a small quantity of lead, which in the process of analysis might easily be overlooked, can be traced even if a considerable quantity of gold salt be used and the toning be sufficiently prolonged. In this case the larger quantity of lead sulphate is replaced by gold or sulphide of gold.

PROFESSOR RODOLPH NAMIAS.

OPTICAL NOTES.

II. THE INFRARED ABSORPTION SPECTRUM OF SELENIUM.

About a year and a half ago the absorption spectrum of a film of selenium, melted between rock salt plates, was found. Commercial vitreous selenium was used. It was found that the transmission varied with the age of the film for the first few days, hence it seemed wise to repeat the work. Since then, through the courtesy of Dr. Carveth, of the Chemistry Department, an opportunity was granted to repeat the observations on very pure selenium prepared by A. P. Saunders.⁵ The results

Fig. 3.

seem worth recording, since they complete the exploration of the spectrum from the ultraviolet to 14μ in the infrared.⁶

The results are shown in Fig. 3, in which curve *a* shows the transmission for the commercial material. The transparency at this time increased with increase in wave-length. Two days later the film was re-examined, curve *b*, when a constant transmission of about 20 per cent. was found throughout the spectrum. This it continued to do, as was found on subsequent examination.

Ordinary selenium contains sulphur, and since the latter changes from one crystallographic form to another soon after it has been melted and permitted to cool, this may perhaps explain this change in transparency.

Curve *c* gives the transmission of pure selenium, examined like the preceding. The dots show the first examination just after melting, while the crosses show the second one made two days later. It is to be noticed that the two curves coincide.

Curve *d* gives the transmission for this film thirty days later. It likewise is fairly constant in its transmission, being parallel, but about three per cent. less than for the preceding dates. This, no doubt, is due to the fact that the film had to be remounted on the carrier before the spectrometer slit, while the surfaces of the rock salt plates may have changed by that amount. The results show that the pure material did not change from a varying to a constant transmission, as was found for the commercial article. The film of pure selenium was made by melting between very clear rock salt plates, heated just above the melting point. The film was homogeneous, and its colour was a deep ruby-red. Thickness, 0.07 mm.; area, 8 14 mm.

It would have been interesting to examine the metallic modification of selenium. But no film could be made procured that was free from rills, so the examination was never made.

The absorption and refraction indices have been determined in the visible spectrum by Quincke,⁷ in the visible and ultra-

violet by Cornu,⁸ and by Wood.⁹ The ultraviolet reflecting power has been measured by Nutting.¹⁰ He found that the reflecting power increases abruptly from a low value in the red to a maximum in the yellow, falls off slightly towards the violet, and then more rapidly in the ultraviolet, which agrees with Wood's observations. Wood thinks that the violet and ultraviolet regions have several bands with maxima beyond $.22\mu$. This point is of considerable interest, because of the high dielectric constant, 10.2, of selenium; for, according to the electromagnetic dispersion theory, the dielectric constant of any substance is the sum of that of the ions, which by acting on the ether waves cause absorption and dispersion, plus the dielectric constant of the ether. It has been noticed that selenium is quite transparent in the infrared, and has no broad absorption bands. Hence, on the above hypothesis, we must attribute this high dielectric constant to the ions whose free periods correspond in frequency to the green, blue, and ultraviolet rays, as surmised by Wood. He also found that, for a film of selenium which absorbs but little of the red, the violet and ultraviolet is absorbed nearly as strongly as a metal film of the same thickness. This is one peculiarity of selenium, occupying, as it does, a position midway between the metals and non-metals. Like the metals (curve *e*, Fig. 3, from Hagen and Rubens¹¹) it has a high reflecting and absorbing power for the visible and ultraviolet rays. Unlike the metals, but like the non-metals (except that it has no defined selective absorption bands), it is quite transparent in the infrared. Hagen and Rubens have examined a large number of metals and alloys to 14μ and found a uniform, high reflecting power throughout the infrared region. They call attention to the enormous influence of the molecular free periods of the metals upon the optical region. The curves impress us with the complexity of the phenomenon of total (of metallic) reflection and the depth of penetration of the same, especially for a metallic film so thin that it is optically transparent, in which case the penetration might be considered infinite—i.e., the disturbance is never turned back, but is transmitted.

Curve *f*, Fig. 3, gives the transmission of a plate of sulphur 3.6 mm. in thickness. Nothing was known about the direction of the optic axis. Since this is a problem by itself, in pleochroism, it will be sufficient to add that a natural crystal, 1.06 cm. in thickness, transmitted on an average about 50 per cent. where this plate of 3.6 mm., but not so highly polished, transmitted only about 38 per cent. As is well known, sulphur and selenium have an extraordinary similarity in their properties, but no such similarity is to be found in their transmission curves. Like the metals, selenium is more opaque than sulphur, and its absorption is general, while, unlike the non-metals, it shows no selective absorption, as is true of sulphur.

W. W. COBLENTZ.

Physical Laboratory, Cornell University.

THE hon. secretary of the West London Photographic Society writes:—It affords me much pleasure to inform you that during the past year the membership of our society has increased about thirty per cent. Our meetings are well attended, the members taking interest in the welfare of the society. We have just completed arrangements by which we have secured the Wycombe Hall for the coming session, the same being larger and more convenient than our old premises. The hall is situated at No. 263, Hammersmith Road (close to the Broadway), and is within easy access of not only the immediate neighbourhood, but also of West Kensington, Putney, Notting Hill, etc. Our annual general meeting takes place on October 7, and the ordinary meetings are then continued fortnightly until May.

THE SILVER "GRAIN" IN PHOTOGRAPHY.

[From the "Astrophysical Journal," by courtesy of the Author.]^{*}

ON THE SILVER "GRAIN" IN A DEVELOPED PHOTOGRAPHIC PLATE, WITH A CONSIDERATION OF THE INFLUENCE OF THE DEVELOPING AGENT AS MODIFYING ITS SIZE OR CHARACTER.

It is a matter of importance to those making use of photography as a means of recording scientific data that a definite understanding be arrived at regarding the size of the silver particles which constitute the image. More particularly is this so in the case of astronomical photography, where the original negatives must necessarily undergo considerable enlargement, in order that the detailed structure of the object photographed may be rendered readily apparent.

In many instances this enlargement is carried to such an extreme that the individual particles of silver composing the negative image become so obtrusive that detail is entirely masked (for close observation) and can be discerned only when the enlargement is held off at some distance. In such a case there is absolutely no gain, but rather the reverse, as it is much easier to study detailed structure of any kind when at the distance of normal vision.

It is with special reference to this usage that the present work was begun, since there are many plates available for the astronomer or physicist, each of which is supposed to combine in itself (according to the manufacturer) those qualities which make them valuable—viz., speed, fineness of grain, and general uniformity.

Speed must necessarily be the first consideration, and this narrows down the number, so that in the present work those selected for test were as follows: Seed 27, "Gilt Edge;" Cramer "Crown;" Cramer "Instantaneous Isochromatic;" and Hammer "Special Extra-fast." In each instance the plates were taken from different emulsions, triplicate exposures being made for all results aimed for.

These makes were selected as being the fastest generally available, and tests for relative speed showed that the point of highest efficiency was about equally shared by the Seed "27" and the Cramer "Crown." The results of nine separate tests (from different emulsions of the same trade brand) showed that, although the latter plate was occasionally a trifle faster, yet the Seed "27" was always of the same uniform speed, and gave the least amount of "chemical fog." The remaining two plates were somewhat lower in general sensitiveness, which may be proportionately represented as 9 : 11 between the "isochromatic" and "27," and 8 : 9 between the Hammer and "27," in favour of the latter.

It is very generally understood that silver bromide (2 Ag. Br.) is the chief substance employed in the making of gelatine dry plates, but that silver bromide exists in several different allotropic forms has long been known—the first formed by the admixture of the gelatine and bromide and silver salts, is of low sensitiveness, but in the process of ripening passes gradually through several modifications, finally ending in a state which is capable of reduction by a developer without the previous action of light, viz., the blue allotope of silver bromide.¹ If the ripening of the emulsion be stopped prior to the formation of this last form, the result is still another allotope, which is green by transmitted light, and of high sensitiveness.

In the process of "ripening," which is brought about principally by an increase in the temperature of the emulsion, the introduction of ammonia, etc., it undergoes still another and purely physical change, viz., the particles of 2 Ag. Br. increase in size, in all probability due to accretion. The measurements of Eder give the particles in the finer unripened emulsion as from 0.0008 to 0.0015 mm., while in the most sensitive form he gives a size of from 0.003 to 0.004 mm.² As stated by Perrine,³

the size in this latter state is approximately 0.0025 mm., while Kayser⁴ places it at 0.001 mm.

Although a more sensitive emulsion certainly means a coarser grain, yet that coarseness of grain is not synonymous with speed is shown by the researches of Luppé Cramer, who instances the use of too strong a solution of nitric acid in the manufacture of the emulsion, or too strong ammonia (or too great a quantity), also an insufficient amount of gelatine; even the shaking up of the sediment during the process of "cooking" is likewise certain to result in coarseness.

Much has at various times been written regarding the value of certain developing agents as modifying the resultant size of these silver particles, and many claims have been advanced by the advocates of slow or dilute development as giving a negative with a very fine grain, and some diversity of opinion exists regarding the plate best suited for the work.

It goes without question that the plate best suited to the needs of the astronomer or physicist is that one which combines the highest speed with the requisite fineness of grain; for in the first case the higher the speed, the greater the efficiency of the telescope or instrument used; and in the second case the finer the grain of the original negative, the greater the available enlargement.

After consideration, the following method was adopted in making the tests as offering the least chance for error (as already mentioned), triplicate plates being made in every case, and at every point throughout the series.

An instrument was constructed upon the same lines as the

Fig. 1.—Scale of Enlargement for Photomicrographs.

Four divs. of ocular micrometer — one div. of stage micrometer;
One div. of stage micrometer (ruling — 0.001 mm) — 4.3 mm; ∴ one div. ocular = 2.3μ.

sensitometer of Scheiner, consisting of a rectangular box open at either end and fitted with forty-two small rectangular cells. One end is closed by a sheet of thin metal in which is made a number of minute holes corresponding to the ends of the small rectangular cells, beginning with one and increasing in arithmetical progression. The plate under test was placed at the other end of the sensitometer and closed in light-tight. Exactly similar exposures were then made to ground glass illuminated by sky-light.

COMPARISON OF SIZE OF "GRAIN" IN THE PLATES CONSIDERED

Similar sensitometer exposures were made on each of the four makes of plates, as previously mentioned, the precaution being taken in the selection of the three plates of each that they should represent entirely different dates of emulsion. These exposures were then developed four at a time, the developing tray containing one plate of each "brand."

A hydrochinone + metol + adurol combination was selected as the developing agent, for reasons which will be obvious as this article progresses. Microscopic and photometric examination of the negatives showed results identical on each plate of the same make.

Photomicrographs were then made from equal opacity squares of one plate of each make, of sufficient magnification to show clearly the individual particles of reduced silver.

Considerable difficulty was experienced in this portion of the work owing to the definite thickness of the gelatine film on the plate and the consequent number of planes, which rendered

¹ Blue by transmitted light.

⁴ "Handbuch der Spectroscopie," 1, 638.

focussing a matter of extreme care. The use of a lower-power objective could not be taken into consideration because the "grain" was not sufficiently resolved, an entirely false effect being thereby produced.

A magnification of + 430 (Fig. 1) being decided upon, the apparatus was firmly clamped and negatives made of the squares selected. At this point the triplicate plate exposure was of much assistance, for, as the field was entirely refocussed between each, the plates served as a check upon one another inasmuch as imperfect focussing brought into the field a new "set" of grains whose position would not coincide relatively with the accompanying two plates; to facilitate comparison and eliminate errors of personal measurement, an ocular micrometer was introduced, and brought to a focus at the plane of the sensitive plate.

It will be seen (Nos. 2-5, Fig. 2) that the grain particles of the Seed "27" plate are decidedly the most regular of the

Fig. 2.—Photomicrographs of Silver "Grain."

2. Seed 27. "Gilt Edge" (1.4 to 1.8 μ). 3. Hammer "Special Extra Fast" (3.5 μ).
4. Cramer "Inst. Iso." (0.6 to 1.5 μ to 1.1 to 3.7 μ). 5. Cramer "Crown" (5.3 μ).
6. Seed 27. Before Intensification (1.3 to 4.0 μ). 7. Seed 27. After Intensification (2.8 to 10.4 μ).

series, while those of the Cramer "Crown" show the largest and most "ragged." It will also be noted that in the case of the isochromatic plate the appearance of the grain particles is altogether different from that shown by the others; for, while the general shape is more or less regularly round or spherical, the isochromatic grain is decidedly spicular.

Examination shows that this spicular grain is not distributed equally throughout the depth of the film, but is almost entirely confined to the surface; for, whereas the film at this point is composed of grains of this character, they become fewer as the lower planes are successively observed, until at the lowest depth (in contact with the glass) they are entirely absent.

It must not be understood that these spicular "grains" gradually change shape and become irregularly round; they are a distinct set of particles by themselves, the gradual introduction of the others being readily seen with a sufficiently high power.

That this form of particle would seem to occur rather generally in isochromatic plates is shown by the fact that from a number of other "iso" plates, exposed and developed in the same way, and including Cramer "iso" plates of emulsions covering a period of eighteen months, Seed orthochromatic, Cramer trichromatic, and Lumière orthochromatic, the same spicular grain was noticeable in each, but varying in amount. The idea that this form of "grain" is inherent in and essential to an orthochromatic film the writer does not advance, there being several probable reasons for the formation, which it is purposed to treat to a further investigation.

Careful visual microscopic examination of these negatives also agrees well with the findings of Luppo Cramer, who states that each particle of Ag. in the negative corresponds to a 2Ag. Br. grain in the undeveloped layer, and that an increase in the exposure and development of the plate shows, first, "that the number of Ag. grains in the upper layer is constant" (or nearly so); "second, the number of grains in a unit of volume increases; and, third, that the size of the individual grains increases;" and to this may be added a fourth point—that the grain particles become more complex by reason of their running together and forming what we may term as a group-particle.

ENLARGEMENT OF THE "GRAIN" BY INTENSIFICATION.

A sensitometer negative was firmly fastened upon the microscope stage and photomicrographs were made. The objective was then swung aside, and the square under magnification was intensified by mercuric chloride, followed by blackening with ammonia, the entire operation being performed by means of a small camel-hair brush. When dry, the objective was replaced in position, and exposures were again made, which was reproduced in Nos. 6 and 7. The enlargement in size of each of the original particles is very marked, measurement of the "before and after" effect showing an increase from about 2.5 μ to 5.0 μ in the single grains, and from 4.0 μ to 10.5 μ in the group-particles. Observation will readily identify the individual grains in these two plates.

PRESENTATION TO MR. ARTHUR PAYNE.

THE Federation of the Photographic Societies of Northumberland and Durham, which dates from November, 1901, owes its founding and a large measure of its subsequent growth and success to its Hon. Secretary, Mr. Arthur Payne, F.R.P.S. Mr. Payne now finds it necessary to relinquish his office as secretary owing to pressure of business. Many members of the Federated Societies have felt for some time that a suitable recognition of Mr. Payne's services should be made, and as the occasion of his retirement from office was felt to be a fit occasion, a presentation fund was started, and met with a liberal response. At a representative meeting held in Newcastle-on-Tyne on September 21, 1904, Mr. A. E. Cowling, Chairman of the Federation, in a well-chosen speech, asked Mr. Payne to accept from the Federation, as a mark of their esteem, a massive solid silver salver bearing the following inscription:—"Presented to Arthur Payne, Esq., F.R.P.S., in cordial recognition of his services as founder and hon. secretary of the Federation of the Photographic Societies of Northumberland and Durham. September, 1904." Mr. Surtees, of Consett, and Mr. Brady, of South Shields, also spoke in appreciation of Mr. Payne's services as Secretary of the Federation. On rising to respond, Mr. Payne met with quite an ovation. He thanked Mr. Cowling and others for the kind expressions they had used concerning him, and the Federation for the valuable gift presented to him. Mrs. Payne and he would always look upon it with pride as the evidence of the good feeling towards him expressed by this presentation. The salver was afterwards handed round, and its beautiful work and choice appearance were much admired. Mr. H. Wallis Wardropper, of Sunderland, acted as Secretary and Treasurer of the Presentation Committee.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

SECOND NOTICE.

CONTINUING our comments on the more noteworthy pictures on view in the West Room of the New Gallery, the works of Wm. Crooke appear to dominate each wall of the exhibition. These powerful examples of portraiture are as characteristically British as some of the specimens of gum work in the exhibition are characteristically French or German. These pictures are all the more noteworthy when we consider that they are specimens of Mr. Crooke's everyday studio work, and have not been specially prepared for exhibition purposes.

Mr. Crooke's method and treatment is perhaps most strikingly exemplified in the figure study of Sir Henry Irving (133). With exactly the same material, we wonder how many other professional photographers would have achieved this result? Its keynote is directness, and simplicity in treatment has not been sacrificed for effect. A careful inspection of this exhibitor's four contributions will repay very careful attention. His portrait of the late Lord Shand we have already noticed, while Robert Maxwell, Esq. (210), and Lord Lovat (239), are very high-class specimens of straightforward photography. Mrs. Barton this year does not appear to have improved on her work of the last exhibition. Whether this is due to lack of fresh models or not we cannot say, but there appears to be a sameness in this clever lady's work that falls after an inspection of a few examples. We trust this difficulty will be overcome in her forthcoming "One-man (!) show" at Russell Square. In No. 33, "The Repose," the title explains itself on inspection. It is but another phase of her now familiar Madonna and child group which scored at last year's exhibition, and is not so good as that effort. The nude child in this instance is awkwardly held, and the flesh is quite textureless. Were it not for the child's face, it might be a large doll the lady is holding. No. 211, "Turn Again Whittington," is another familiar face in a new guise. The lighting of this head is very effective, and the "poise" is good. No. 258, "The Cherry Girl," is the best example of Mrs. Barton's work in the show, and would be completely successful if not quite so pinky in tone. As an example of flesh modelling it is first class, both the face and the cherries, with which the little maid is bedecked, are delightful. Of A. H. Blake's other contributions, in addition to "Blown Sand and Shadows" previously mentioned, we like "The Old Bowling Green" (209) the most. This is one of the best examples of "open door photography" we have seen. The interior of the old hall, with a peep at the bowling green bathed in sunlight seen through the open doorway, is faultlessly rendered.

The Rev. H. R. Campion has only one picture in the exhibition this year, "The Staircase." This is a clean little print of a not very interesting subject, but it is remarkably well done and displays sound technique. F. J. Mortimer's other two pictures, in addition to his medalled work, "The Reef" (144) and "The Majestic Main" (9) already referred to, are "Sea Horses" (172), one of the largest prints in the exhibition—a breezy seascape, with tumbling rollers that give the title, and a fine sky. "A Winter Sea" (124) is rather killed by the frame, which is much too dark for so light a print. In a lighter frame this representation of sullen rollers breaking over rocks would be very effective and true to nature. W. M. Coultas' "The Four Sisters" (51), is an exceedingly fine landscape, or, rather, tree study. The composition is good considering the material, although there seems a certain weakness on the left. The picture is considerably helped by the clouds. "A Woman of Etaples" is not quite successful in representing the action that should be there, and the figure is rather too low in the print.

J. H. Gash's "Smithy" (69) and "Hold Up" (204) are broad in treatment, as most of this exhibitor's figure work usually is. W. T. Greatbatch is well represented by four examples of good photography, of which we think "The High Street, Campden," is the most successful. It is one of those difficult problems of lighting that Mr. Greatbatch delights to tackle, and here we have the darkest of archways and cast shadows in juxtaposition to the brightest of sunlit streets seen through the archway. The shadows are, however, full of detail and highly luminous, while the vista is not too hard. This little picture is worth a lot of study. "The Marsh" (134) is not strong. It is a good composition, and the rendering of distance is admirable, but the whole is rather flat. "The Glade" (257) is better. Here we have a sunny woodland scene that just misses being a very

fine thing. It is not quite sunny enough, although sunlight is well suggested. There is a lack of concentration also in the composition, and, considering the mass of detail present in the foliage, etc., a great amount of breadth has been retained.

Dr. C. F. Grindrod's second picture, "Going to the Meadow" (10) is not so satisfactory as some of this worker's earlier pictures, and hardly rises above the snapshot stage. The treatment of the enlargement, however, is good, but we think the roadway leading off of the picture on the right should have been toned down considerably. W. A. J. Hensler's work this year is also not up to his usual standard. "A Thames Carrier" (45) is very poor. The sailing boat is almost exactly in the middle of the picture, and the clouds are badly printed in. The water, however, is well rendered.

"Reflections" (128) is better, but here again the composition is weak. The mass of boats and sails are too huddled up in the upper right hand half of the print, and the left hand half is almost blank. The saving point of this picture is the delightful reflections of the sails in the water. "A Swollen Stream" (247) is quite ordinary. Furley Lewis's "Peter Kropotkin" (224) is one of the best portraits in the room, and if it had been for competition would, doubtless, have scored. As an exercise in successful studio lighting this admirable likeness of the Russian Prince and scientist would be hard to beat, and should add considerable lustre to Mr. Lewis's fame as a successful photographer of celebrities.

J. C. S. Mummary's two contributions are also "not for competition." "A Fen Village in Winter" possesses beautiful quality for a gum print, which we presume it is. The slight falling away in tone on the left hand side may be considered a fault, but the excellence of the remainder of the picture amply compensates for this. Arthur Marshall's four pictures are all characterised by super technical excellence, in addition to admirable composition and clear workmanship. His medalled picture, "Devotion" (1), has already been commented upon. "The Last Rest" (82) possesses magnificent quality. Two recumbent figures on a tomb, and a pillar and part of an arch vault, are somewhat difficult materials from which to make a successful picture, but here no fault can be found with composition, lighting, or execution, and the result is one of the few pictures in the gallery that will bear repeated investigation. We consider this a much finer photograph in every way than his medalled work.

We congratulate Mr. Marshall, also, on "The Garden of Sleep," a splendid foreground study of flowering weeds overgrowing this pathway to a ruined doorway, and "Shadows" (163), a remarkably clever and satisfying picture from very indifferent material. The back of a cottage, two bare tree trunks and a cobbled pavement—and a gleam of sunlight; without the latter there could have been no picture. The shadows cast by the branches of the trees—themselves invisible on the cottage wall, and the shadow cast by an adjacent building of the cobble stones, make a picture that speaks much for its author's perceptive powers. "La Terre," by P. Bale Rider (77) is a striking composition, and has been achieved with simple materials. The figures of a man and woman digging, with landscape and glowing sunset behind. The lighting is extremely well managed. "November" (182), by the same exhibitor, is one of the best landscapes in the room, and as an example of hazy-weather photography is very faithful to nature. Mr. Rider should stick to this kind of work.

J. S. Lamb's "Salome" (108), is a successful semi-nude that does not offend in any way. In looking at this picture one almost forgets it is a photograph of a posed model. The dish in the lower part of the picture might have been a trifle lower in tone. John Hepburn's four pictures are all sound photography. We like No. 113, "The Village Doctor," the most. This clever arrangement of figures is a form of photography that should be encouraged, as it brings out not only the abilities of the photographer in dealing with figures in such a manner as to tell a story, but also shows the process at its best. There is little or no call for faking or hand-work here, and the result achieved by direct photography is quite as pleasing and satisfying as anything produced by the advanced schools of "Art" photography. E. T. Holding has again two of his delightful and somewhat curiously lit figure studies hung this year. "Building the Bridge" (116) is charming by its unconventionality, the chubby little child playing with some scattered toy bricks is very well done indeed.

"Summer" (331), Mr. Holding's second print, is distinctly clever, but the trimming off of the lady's parasol seems hardly satisfactory. James C. Batkin's "Repose" is good in many ways. Not only is a somewhat morbid subject—a cemetery—idealised, but

the quality of the print is such that it will bear a lot of careful study and thought. "A Warwickshire Lane" (122) also possesses delightful quality. "The Vesper Hour" (148), by Bertram C. Wickison, is very reminiscent of J. H. Gear's work last year, and leaves little to be desired. S. L. Willard, an American exhibitor, has one or two striking things.

"Deepening Shadows" (299) is a quaintly composed landscape, bearing out the title excellently. A hilly road and the last gleams of sunlight are admirably caught to convey just the air of mystery necessary. "Her First Run" (334) is not quite clear, but apparently represents a young lady in the cab of a locomotive, taking instructions from the very American-looking engine driver. The lighting is well managed. Messrs. Haweis and Coles show two striking works in "Crepusculum" (320) and "Portrait of Auguste Rodin" (306). The former is a somewhat inexplicable nude, and the latter a very "strong" portrait study in gum. Carle Semon, another American worker, displays considerable power in "Portrait of an Artist" (308). This photograph possesses wonderful quality, and is pleasing throughout, in spite of the brilliantly white shirt the artist is wearing. "A Boy" (340) is equally pleasing, the flesh textures being remarkably good. The ball held by the boy is perhaps a trifle too insistent. J. C. Strauss' "Mrs. Hunter of St. Louis" (301) is good portraiture, but details of the shadows are lost in general darkness, and the white mount is not quite happy. J. Steele's "In Old Touraine" is a striking street scene with figures, but a trifle weak on the right-hand side. The effect of strong sunlight is admirably rendered. A. A. Bellingham shows two pictures of rather unequal merit. C. B. Howdill's big picture "The Modeller" is rather unsatisfactory in pose and tone, and Ellis Kelsey's "Ride by Night" has too much obvious hand work to be pleasing. We miss the beautiful flower and fruit studies that J. M. C. Whitehead used to favour us with. This year all his work is of the landscape class, and, although admirable in every way, we should still like to see an occasional example of his former ability. No fault can, however, be found with his four specimens of skill as a landscape photographer on view this year. We do not care for Mrs. Jeanne E. Bennett's "Woman Churning" (65). It is rather too fuzzy, and the woman appears to be somewhat enveloped in the tree behind her.

C. J. King has one little seascape hung this year, and it is a little gem, full of action, but erring a trifle on the dark side.

A. R. Sargeant has a couple of excellent shipping studies, but the sails are rather too solid to convey the idea of canvas.

S. G. Kimber has one small architectural subject, "The Monk's Entrance," which possesses first-class technical quality, and "Lowbb," by J. P. Bushe Fox, possesses a fine dramatic sky, as also does Thomas Wright's "A Break in the Clouds." "Solitude" and "Hoar Frost," by the same worker, are fine examples of mist photography and atmospheric effect. Wm. Clayden's "Gleam of Light" is also a good rendering of mist with the sun breaking through. Wm. A. Clark's four architectural studies are up to his usual high standard of work in this branch of photography, and Wm. Rawlings also has four excellent pictures hung, all of which are worthy of note. C. C. Cook's single contribution is a well-managed street scene. Fredk. Hollier's portrait study can be hardly considered representative.

Howard Mercer's "Hazy London" chief claim for attention is that it is the smallest print in the show. M. Arbuthnot's "Harvest" is big in treatment, but too fuzzy in execution. T. Percivale Padwick's "Towards the Close of Day" is well done.

"Sunlight," by E. Salusbury Tardrew, is a successful picture of the "open door" type. S. R. Brewerton's "Pool, Kardassa," is one of this worker's well-known Egyptian studies. The figures in this case are rather conscious. "The Inn Yard," by Bernard Moore, though well done, is not so good as many things we have seen from this versatile worker. Hilda Stevenson's portrait studies are examples of sound photography and lighting. P. R. Salmon's "Portrait of Miss B." is a good straightforward enlargement, and the last picture in the pictorial section is an admirable little street scene by Arthur W. Walburn. Pictures by Dr. T. G. Crump, Oscar Hardee, Avendish Morton, James Auld, H. W. Bennett, G. H. Bowley, J. Page Croft, Dr. F. Groves, Harold Hood, H. C. Leat, Hector Macan, Hector Marchison, Arthur Payne, Sidney Pitcher, Dr. Otto Rosenheim, H. Gordon Stollard, W. Thomas, F. G. Tryhorn, G. J.

T. Walford, and Samuel E. Wall, are also worthy of note, but exigencies of space allow only a brief reference to these well-known exhibitors.

In the first notice of the Royal Photographic Society's Exhibition, contained in our last issue, we omitted to include among the awards the medal to Dr. C. Thurston Holland for his interesting series of radiographs showing bone diseases. The section devoted to scientific and technical photography in which this award is made will be reviewed at length in a future number of the JOURNAL.

INVITATION SECTION.

THE success with which the Royal Photographic Society organised last year the first invitation section held in connection with its long series of exhibitions has induced it to repeat the experiment, and sober judgment will allow that it puts before those British photographers who do not claim, as do some, to have got beyond the learner's stage a collection of nearly two hundred works which is well deserving of consideration. One cannot help recalling the opposition which was so sedulously preached by certain self-appointed guardians of all that is artistic in photography when it became known last year that the Society was likely to extend the scope of its exhibition and poach upon what they thought their preserves. Having no wish to dwell upon the incident, except as a prelude to a protest against the recent misrepresentation of the Invitation Sections of this and last year's exhibition that has appeared in a leading daily paper, which has been made to announce that, "this year as last, British photographers have failed to respond to the invitation of the Society to contribute to its loan sections."

It cannot be too clearly set forth, in opposition to this uncorrected statement, that British photographers have not been invited this year to contribute to this section, which is devoted exclusively to foreign productions, and that last year the organised opposition to the section entirely failed to rob it of its value and interest. This oft-repeated opposition and misrepresentation defeats its own object, however, and is likely to do little else than bring the best aspects of an excellent medium of artistic expression into disrepute. There can be no monopoly of photography, whether in its artistic or scientific applications, and the sooner this truth is recognised by those who, after all, make the exhibitions, as apart from those who organise them, the better.

The section under notice will attract the visitor still more readily than did its counterpart of last year. It consists principally of collections from the members of the Hamburg Society, the Belgian group of workers taking the title "L'Effort," the Salon Club of America, and the Association Belge de Photographie. Other examples from miscellaneous Continental workers more or less known in this country complete the collection.

It is inevitable that an open invitation will produce works which are by no means uniformly excellent. We have no hesitation in writing that the South Room, in which the section is arranged, contains examples whose quality is very poor, judged by even a very low standard, but they hang side by side with productions of undoubted excellence. There is no absolute necessity to hang as many prints as will be found in this section, and the removal of a number which could be easily decided upon would greatly improve the collection. The Society is evidently opposed, however, to the idea of tampering with invited works, and in this we think it is assuming a correct attitude.

Taking the prints as they are arranged, instead of allowing the somewhat startling collection of the Hamburg workers to engage his attention, the visitor will find some thirty-three examples of American photography as practised by members of the Salon Club of America. This youthful organisation, which is not lacking in energy, and of which we believe more will be heard, shows some clean specimens of camera work, prominent amongst them being Mr. Walter Zimmerman's two prints, "Solitude," and "St. Anne's Day," his third effort, "A Breton Crucifix," being less convincing. "Shadows on the Dunes," a warm brown print on thin Japanese paper, by Miss Fedora Brown, is clever, and the best of her three contributions, while Mr. R. L. Week's "Mississippi" and Mr. W. H. Porterfield's "The Day is Done"—a man toiling home in the failing light—are worthy of attention. The latter has a good little snow piece, "A Winter Upland," which, however, gives way in our opinion to "Over the Hill," similar in character, and very creditable, by Mr. Osborne I. Yellott. With a few exceptions—these

being merely commonplace, but not in consequence lacking in some of the qualities for which we look—the American collection is good, setting forth, as it does, the healthier side of the art instead of those aspects to which the extremist would entirely devote this photography of ours.

The Belgian exhibits are in two groups. Amongst the first, the picture entitled "Coucher de Soleil sur la Meuse," by Leonard Misoune, at once rivets attention. It reproduces a very characteristic mood of a beautiful river, and is decidedly in front of the same worker's five other prints, each of which is highly creditable. Mr. Haussens emerges from a not too easy task in his "Vieille Porte," an old gateway plunged in shadow with brightly lighted white walls in close companionship. His other prints also aim at a rendering of sunshine, and very well do they succeed.

There are many other prints we should like to name and criticise, but to do so would absorb more space than we can devote to this section.

The third wall bears without question the work that will receive the greatest attention. We find, not one but eight or nine large prints measuring 36 x 24 in red, blue, or brown, or the glory of polychromatic impressions. We have already described these prints, which hail from Germany, as startling, but this is not all, for none but the narrowest minded will deny that they combine evidences of the exercise of a thought, an artistic feeling and a boldness of execution which it is refreshing to perceive.

Such workers as Dr. Bachmann, Dr. Arning, Otto Scharp, G. H. Grell, H. W. Müller, G. E. B. Trinks, R. Dührkoop, Bernard Troch, Th. and O. Hofmeister, Ulrich Brandt, combine to offer us a really excellent exposition of some of the applications of photography, and each print might with good reason be the subject of some comment.

To name a few, Rektor W. Bangow shows a number of fine prints in several colours, the process, as in most of the German exhibits, being, we believe, gum bichromate. His study of a poverty stricken old woman and child in a doorway, entitled "Des Lebens Eingang und Ausgang," and his "Zurischen Feld und Wald," in which beyond a brightly lit mass of flowers and corn on either side of a footpath, rise the dark recess of a wood, are those which appeal to us more particularly. Dührkoop's fine large portrait studies are amongst the best in the exhibition, and Bachmann's "Schnee" is a veritable "tour de force," being one of the most realistic snow pieces seen in this country. All of the prints are highly decorative and should not be overlooked.

The German group is followed by the second Belgian collection, the prints in this being by comparison somewhat small and retiring owing to the absence of colour. Mr. Victor Stoff's "En Vieille (castille)" and his sketchy "Tête Sanguine" stand out well, as do Leopold Willems' "Lac de Sarde" and "Canal à Venise." Leon Sneyers' "Les Pavures" is strong, but his other prints are not above the average. C. R. Mathy essays that most difficult study, the representation of the nude, with some success, and Julien Putman shows a bright little picture of girls playing seesaw on the sands. The strong sunshine is here well handled, and the result is good. Altogether, the Invitation Section is quite justified, and we hope that the society will be persuaded to continue the series and show us what others are doing whether the general quality is or is not as high as rigid selection might make it.

FORTHCOMING EXHIBITIONS.

- October 4.—Whitehaven Y.M.C.A. Zoar Photographic Exhibition. Hon. Sec., J. Hayward, 14, Albert Terrace, Whitehaven.
 October 15 29.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.
 October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.
 October 19 20.—Isle of Wight Photographic Society. Hon. Sec., J. Howard Burgess, 53, Pyle Street, Newport, I.W.
 October 19 22.—Rotherham Photographic Society. Hon. Sec., H. C. Hemmingway, Tooker Road, Rotherham.
 October 26 28.—Watford Camera Club. Hon. Sec., H. G. Trayfoot, 3, The Parade, Watford.
 November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Bambygate House, Newark.
 November 2 23.—Plymouth. Hon. Sec. Photographic Section, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.
 November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.
 November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.
 November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.
 November 15 19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, 52, Frederick Street, Sunderland.

- November 17 18.—Baintree and Bocking Camera Club. Hon. Sec., W. H. Tilston, 81, High Street, Baintree, Essex.
 November 17 19.—Darwen Photographic Association. Hon. Sec., J. G. Thomas.
 November 21 26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
 November 22 23.—Ipswich Camera Club. Hon. Secretary, Sutton, 37, Henley Road, Ipswich.
 November 23 26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.
 November 24 25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.
 November 25 26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.
 November 26 27.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmar Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.
 December 2 8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.
 December 5 17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102 West 101st Street, New York.
 December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
 December 12 17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubery, 3, Langdale Road, Sefton, Liverpool.
 December 13 20.—Southampton Camera Club. Hon. Secretary, G. Kimber, Oakdene, Highfield, Southampton.
 December 28 31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.
 January 12 14, 1905.—Boston Camera Club. Hon. Sec., H. Hames, 65, West Street, Boston.
 January 14 28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.
 January 20 21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.
 January 28 February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.
 February 6 11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James St Cottage, Blairgowrie.
 February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Glasgow.
 March 4 11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.
 June, 1905.—Northern Photographic Exhibition. Secretary, H. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

- September 30.—"Photographic News." Quarterly Competition. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.
 October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.
 October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.
 October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.
 October 31.—Coxin. 68 prizes for users of Coxin. Judging two pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.
 November 1.—The "Graphic." £50 in cash prizes. Manchester Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.
 December 31.—Barnet. Nineteen classes. Prizes valued at £100 for lantern slides and prints made with Barnet products. Elphinstone and Sons Limited, Barnet, Herts.
 March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

THE Hackney Photographic Society's Exhibition.—The sixteenth annual exhibition of the Hackney Society will be held at the K. Hall, Hackney Baths, N.E., on November 9 to 12. The judges will be Messrs. H. W. Bennett, A. Forsley Hinton, and A. Mackie. open classes are announced and the awards are specially designed plaques. Exhibits will be collected without additional charge at the R.P.S. and Salon Exhibitions. Entry forms can now be obtained from the Hon. Sec., Walter Selfe, 70, Paragon Road, Hackney.

ASTRONOMICAL PHOTOGRAPHY AT OXFORD.

CONSIDER how many of the thousands who daily pass one or other of the two observatories in Oxford have any idea of the work that is done in them, or of the life that the astronomer leads? observes correspondents to the "Oxford Chronicle." We should not be surprised to find that many persons, if questioned, would be found to hold a vague notion that the astronomer has to sit up all night and look at the stars; and so, of course, he goes to bed and sleeps the day. As to the purpose and result of all this star-gazing, would probably be found to have still more hazy notions, and would be surprised to learn that the astronomer is the one man of others on whom we are most dependent for the regulation of our everyday life. In other words, the astronomer is "the man and the clock"; and it is his first and most important work to set the clock exactly to correct time. That is to say, he must make it so that it registers the lapse of twenty-four hours in exactly the period of one revolution of the earth round its axis. This is a work which involves the use of very accurate instruments, and great care in observing, and also in making the subsequent calculations. But this is not all his work. It is part of his duty to map the heavens, and keep account of all the stars he finds therein. The oldest time this was a laborious task, wrought mainly with simple instruments; but in modern days the photographic plate has come to the aid of the astronomer, and star charts are compiled of what is known as the "equatorial" telescope. This is in a circular dome, entering which we find ourselves in a circular chamber. The centre of it rises the great masonry pier which supports the instrument. Close against the pier is the cylinder of the electric engine that moves the floor up and down in obedience to the astronomer's will, for if the star is low in the sky, the eyepiece of the telescope will be high up. In most observatories the way of observing under these conditions is to mount a movable platform and reach the instrument in that way, but in the new dome recently erected at the Radcliffe Observatory, a moving floor has been fitted, and by simply pulling a rope the observer can raise or lower the whole floor, thus not only enabling him to observe with comfort at any position of the telescope, but taking with him his desk with his tables and notebooks. On the other side of the dome is a small dark room, where the plates can be changed; and a powerful water engine whose office it is to wind up the clock which drives the telescope. As the clock weight scales about half a ton, it will be seen that water power for the winding of it is by no means a superfluous luxury.

Ascending the staircase, we reach the floor—now at its lowest point—and get our first sight of the telescope itself. A huge mass of tubing, mounted on one end of a long beam, pivoted near the centre, and carrying a weighty counterpoise at the other extremity, rises in the midst of the steel pillar which sustains the vast instrument. The driving clock—a maze of many-toothed wheels and electrical machinery. "The driving clock?" asks one of the uninitiated. Know, that the field of view of a telescope is very small, and as the earth is constantly turning, prosaically carrying with it even the astronomer and all his goods, the period during which a star remains in view with a powerful instrument is very brief, lasting only to some few seconds, unless the telescope be moved to follow the course of the fugitive. Fortunately, we know the course the star will follow in its apparent motion (because we really we who move, and not the star), and so we can mount the instrument in such a way that a simple motion in one direction will keep the object in sight as long as we desire, and to save trouble and ensure regular speed, a clock is employed to impart the necessary amount of movement. But this clock cannot be trusted fully, any more than can the chronograph recorder of the transit instrument; and in this case it is no wonder, for the equatorial weighs seven tons, which is no small item for any clock to control. We see a solemn pendulum fastened to the wall, whose duty it is to beat seconds and keep the driving clock running strictly to time. But the pendulum itself must work correctly, and to ensure that it does so it is every now and again made to register its beats on the recorder in another building, by which means it can readily be compared with the standard clock, and its rate of going corrected, if necessary, by the addition to its bob of small pieces of metal, the weight of which, though trifling, is sufficient

to make it lose from one to one hundred or more seconds in the course of a day.

And the telescope itself? Do not run away, dear reader, with the idea that it is anything like the collection of sliding tubes and lenses you have so often seen under the arm of the coastguard'sman on the shores of our island home. Two large tubes of sheet steel, lying side by side, and securely bolted to the heavy axis, appear before us. The one is fitted with an eyepiece, and is for visual work; the other is for photography, and is, in fact, a giant camera, with a focal length of between twenty and thirty feet. All about it are levers, and screws, and graduated scales, till it appears to the non-professional eye a most complicated affair; and in very truth it is none too simple, even to its masters.

Most of us have taken photographs of some moving object. But what if we had to give a time exposure on some object in motion, following its movements with the camera, so that the image on the plate should remain stationary? Even if we knew exactly in what way the motion would take place, I think we should most of us shrink from such a task; yet this is what has to be done every time a photo is taken of any part of the starry firmament. Of course, as already explained, the driving clock does most of the work, all the work, indeed, of actually moving the telescope; but as the least deviation if unchecked, would increase and ruin the plate, it is necessary for the astronomer to keep an eye on the star the whole time that the plate is being exposed; and since exposures vary from five minutes up to as many hours, it will be seen that the work of the photographic astronomer is not an altogether enviable one. And many and many a time does it happen that perhaps half-way through an important exposure the clouds will creep up and interrupt the proceedings, it may be for the rest of the night. This need of checking the action of the clock is the *raison d'être* of the visual and photographic instruments being combined in one. While the plate is being exposed in the one the observer is watching through the other. In the centre of his field of view are two fine "cross wires" at right angles, and when photographing a given portion of the heavens a particular star is selected, and the instrument adjusted so that the image of that star appears on the intersection of these "wires"; and if during the exposure it leaves it in the slightest degree, a switch is depressed by the patient watcher, and the clever current pulls up the clock, or urges it on faster, as the case may be, until the star is once more in its proper position. This is perhaps the most tedious of all the work that goes on in the observatory; yet it is the work which yields the best results in the plotting out of the new star charts. After the plate has been taken and developed, there is the work of measuring it and recording its results in tabular form, and this, too, demands the use of instruments of the utmost precision, and the most unremitting care. The professional astronomer has but little time to spare for the romantic side of the star world; it has all to be very matter-of-fact business with him. Yet it is work that is not without its peculiar compensations; and perhaps no other scientist ever experiences quite the same thrill of delight as the observer who finds on his plate the tiny trail that denotes a planet, which he can prove unmistakably to be a new one, or, better still, when, after carefully measuring the position of a star of some considerable magnitude he finds that it has never been recorded before, and is therefore an undeniable "Nova."

But the great work is the correcting of the standard clock; and though all the official work in this direction (for England) is done at Greenwich, yet the work of the provincial observatories greatly aids the Greenwich staff in other highly important branches, and materially adds to our knowledge of the great universe.

The inventor of the Crossed Swords Pigment paper (supplied by Chas. Zimmermann and Co.) has discovered a method which removes what was perhaps the only part of the process which entailed any trouble at all, i.e., the acetic acid bath. He has found that this bath may with advantage be substituted by immersing the print in a tepid 6 per cent. solution of soda bicarbonate, which is not only simpler in use by reason of its not requiring to be kept at a given temperature, but it removes any possibility of rotting the pigment and so losing some of the finer detail, which was a danger with the acetic acid bath. The resulting print is also softer in appearance and not so inclined to contrast. The prints may be handled in larger quantities, and may be left in the bicarbonate solution without danger of deterioration.

ON "OPENING A NEW LINE."

It is a singular fact that the professional photographer is seldom a good man of business. He may be a clever technical worker, instinct also with that artistic taste and sympathy which are emphatically necessary for successful portraiture. He may be, better still, possessed of that tactful and winning manner which pleases the sitter, but still the one thing, from a pecuniary point of view even more important than all the preceding virtues, is lacking—the ability to so keep himself in the public eye, and to push the attractiveness of his wares, that he need never sit down and wait for custom.

No doubt a certain amount of this failure to grasp the essentials of business prosperity arises from a species of false pride, a kind of traditional sentiment that the photographer has a distinctive professional status to uphold, and so must carefully abstain from undue advertisement and commercialism. There is, of course, much to be said for this view of the matter. No zealous lover of the camera craft would wish to see anything done which could at all lower the estimation that the public instinctively feel for at least high-class photography, or which would tend to degrade it into a mere trade. But it is questionable whether this has not already been done to such an extent that the worker who omits to captivate his clients by a sufficient amount of well-judged pushing and puffing is bound to go to the wall. It is infinitely regrettable that the profession of photographic portraiture should have allowed itself to sink so far into the present abyss of suicidal competition, with its resulting low prices and surplus of unemployed; and it is doubtful whether some degree of blame ought not to be attached to the short-sighted policy of those workers who, once entrenched in an easy and lucrative position, could find no means of preventing or avoiding such a pass. That, however, is over and done with; the photographer of to-day must take things as he finds them, and make the best of the prevailing conditions.

For all the complaints of bad business so persistently heard, the amount of photographic work actually done is by no means so large as it might be if an intelligent attempt were made to open fresh sources of custom. An illuminating instance of this may be given. At a sleepy little south coast watering place there were, until a year ago, seven photographers of varying grade. There was the leading man, with a smart, double-fronted shop on the parade, his windows filled with portraits of his Worship the Mayor, the local clergy, and other dignitaries. Three or four second-rate men catered for a middle-class connection in different parts of the town, while the remaining studio might be placed without serious libel in the catalogue of the "cheap and nasty." The amount of business done fluctuated, but it would have been heartily agreed by any observant looker-on that there was absolutely no chance for a new-comer. The aristocratic owner of the studio on the front just managed to decently clear his expenses and leave enough for an occasional visit to the theatre with his family. The four middle-class studios were commonly in a chronic state of insolvency, and frequently changing hands. The cheap worker, curiously enough, did rather better, but had to be content with a tremendous slump in the winter season. Such was the position of affairs when; hardly twelve months ago, an enterprising citizen of Yankeeedom, greatly daring, started a new establishment on the front. Unlike the usual run of his compatriots he did not seek to introduce strikingly original methods of work or advertising, but, beyond the fact that his premises were in every respect handsome and up to date, pursued his way in quite the orthodox fashion. And yet, simply by reason of a keen eye for display and an eager seizing of every possible opening or suggestion of business, it has come to pass that, without at all affecting the amount of work done by his seven predecessors, the American now takes five times the receipts of all the others put together.

The fact of the matter is the British photographer is too apt to forget that portraits are not a necessary of life, and that, therefore, he cannot well rely upon a steady and continuous flow of orders if things are left to themselves. It is no good to take the business that comes, the business that is already there. He must create a new demand by perpetually arousing fresh interest in previously undisturbed directions. He must, in fact, take a leaf from the book of the wide-awake modern tradesman, and "open a new line."

It might be thought that there is very little scope for the introduction of anything really new and original in the photographic business. That such is not the case is amply proved by the remark-

able success now attending the offer of miniatures at a low, probably remunerative, price by a widely circulated daily paper. is a source of income which scarcely one photographer in a dozen cared to turn his attention to, and now, as with the bromide enlargement, it is the outsider who reaps the benefit. The public demands a novelty, and the wise man of business knows how to supply this at just the right moment. It is a common delusion a thing, to be new, must be absolutely novel. It may be employed out in one county and quite a rarity in another, and the local differences should be critically noticed. We remember a well-known worker telling us that his specific for the improvement of business was to go all round the neighbourhood examining his rivals' showcases, and to make a speciality himself of whatever he found others had not got. Incredible as it may seem, there was actually a small town in which, till quite recently, the carte-de-visite had disappeared from all the photographers' showcases. At last, it appeared, one of them noticed the omission, filled his windows with cartes, and is now inundated with orders.

It is the law with everything else, and the photographer cannot expect to ignore it with impunity—something becomes popular, its day, and then steadily declines in public estimation, giving place to a fresh favourite, until, perhaps, the once successful draw becomes so utterly forgotten that it may be safely re-introduced as a novelty good for a second run of prosperity. It is often in the revival of formerly popular but now neglected fashions that a striking success may be achieved. Many examples will readily occur to prove the truth of this to an investigating mind. The renaissance of the miniature is a case in point, and there are numerous other instances every branch of industry and art. What is required is simply a moderate portion of that prophetic foresight which enables one to anticipate what will take the public fancy, and the executive ability to take advantage of and fully supply the demand so created.

Even without the introduction of actual novelties or the revival of past processes and methods, there is ample scope for the presentation of the photographer's present work in a fresh and more attractive light. A new line may be struck in the display of specimens, the decoration of windows and showcases, just as surely as by any other way. The value of frequent change in the showcase or window is not appreciated as it should be. It no doubt involves much extra work and trouble in the preparation of suitable specimens, but this is generally amply repaid. It is better to show only a few specimens with frequent changes, than to have a larger display which is sufficient to become tame and commonplace in everyone's eyes by reason of long familiarity.

It is inevitable, of course, the moment a new line is started, or anything fresh and original introduced in the conduct or methods of business, that imitators will immediately follow suit. This may be expected, but the enterprising photographer will have gained only a momentary start of his rivals but, in many eyes, a reputation for smartness and up-to-date ideas which will linger with him some time. It must then be his object to maintain every temporary advantage gained, and to keep ever to the front in all that is bold and unhackneyed. All this can be done without in the least diverging from a dignified and self-respecting professionalism—in fact, what is contrary to this simply spells failure sooner or later. The man who merely thinks of the present moment, straining all his energies to a temporary triumph over his competitors by an undesirable cut of prices that are already too low, or by other penny-wise and pocket-foolish tactics, may profit exceedingly for a few short months, but will in all probability soon realise with disgust that he has succeeded in permanently damaging not only his neighbours' businesses, but his own as well.

A. LOCKETT

YEADON Photographic Club Sold Up.—The erstwhile flourishing Yeaddon Photographic Society is now dead, and they were sold up Tuesday night last, a melancholy event in face of what might have been the opening of another winter session. Members, however, not attending, interest gradually lapsed, and so the club went down. Little debt remained to be cleared off, and therefore the goods and chattels were disposed of. These included an enlarging camera, fitted with dark slide, lens, and carriers, up to 15 by 12, optical lantern with condenser, lens (with flash shutter), and metal carrying case and lock; and a number of sundries.

FRAMING AND MOUNTING.

MR. JOHN H. GASH has given some instructive advice on this subject at a meeting of the Leeds Camera Club.

Framing, he said, is a question upon which there may be considerable difference of opinion, and a frame one man would condemn another might gloat over. But frames intended for exhibition purposes must be considered from a different standpoint than those which are to be hung up at home. For the former purpose, the quieter and more subdued the frame the better accentuated will be your picture and that is the main object of the exhibition frame. But while giving subordinate to the picture it encloses, it should be in strict harmony and harmony with it, otherwise the observer's attention is attracted by the frame, which ought to be drawn to the picture.

Light delicate prints are often seen at their best when framed close up without any mount showing. But when we turn to the question of mounting, we are confronted with a matter on which there is a wider divergence of opinion. Some foreign works, which were exhibited in Leeds a year or two ago, were excellent examples of grotesque in mounting, and showed how it might be carried to ridiculous extreme. After tone, a secondary consideration should be the subject, when deciding upon the style of mount and frame. Whether the print shall be framed close up or surrounded by a mount, must be determined largely by the type of subject. Strong, heavy subjects, large figures and the like, are, as a general rule, better, and appear more artistic, when framed close up. But in coming to a decision on such matters the photographer's own judgment comes in very largely, and may be said to depend upon the subject and type of printing process employed in producing the print, and it is always best to judge the print in connection with its subject and colour. For exhibition work it may be said, generally speaking, that if the tones of the print permit it, it is best to frame close up, but if the tones are found to be unsuitable for this purpose will then be best to have a decided contrast, and separate the frame from the print by means of a mount. As an example of what he meant by suitability of tones, Mr. Gash referred to a brown carbon print on stained oak frame, remarking that if the tones of the two were in harmony we should, standing at a distance, see the picture but not the frame.

But some subjects will not admit of being framed close up, and must be mounted on suitably toned board or paper. Certainly, if the print and mount be in perfect harmony the former will gain very much by such treatment. White mounts, as a general rule, are unsuitable. At exhibitions all frames with white mounts are relegated to the corner to themselves. Remember, the frame and mount must be entirely subservient to the picture.

For "home consumption" the mounting and framing may be treated as a decorative point, so that it may be in harmony with other things, furniture, etc., in the room. A lighter type of frame may be employed—some with a little gilt or silver may be effective. But these matters let your own taste as to what you like on your own walls be your best guidance.

The question of mounting is a matter of personal equation, and we cannot lay down too hard and fast rule. Generally one must decide what is best suited from an artistic point of view. A thing may be decorative and artistic, but it does not follow that it can be artistic and decorative.

For general work it is best to avoid extreme degrees of mounting. Numerous tints and tones and colours in juxtaposition often become grotesque, if not altogether ridiculous. The colour of the mount and the depth of tone is the first and all-important consideration. Natured mounts can now be purchased in a great variety of neutral tones, and it is a good plan to try the print on one after another until which suits it best is found.

White margins to a print are, perhaps, best got by masking in the print, rather than by employing an additional mount; and if a narrow black margin is wanted, this can be made by means of pen and Indian ink. The same effect as a multiplicity of mounts is so achieved, but much more easily.

In conclusion, Mr. Gash showed a number of home-made mounts, including an ingenious and exceedingly neat "cut-out" mount on a toned bevel opening.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
1.....	Royal Photographic Society ...	<i>Photographic Studies of Marine Life.</i> Mr. F. Martin Duncan.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 22, 1904.—Mr. Wright in the chair. Mr. Henderson showed a portrait of himself taken by Mr. Pfenningeert, of Brighton, by the Davidson and Juneaux process in Davidson's patent reflecting camera, with an exposure of 40 seconds in bright light out of doors. He did not altogether like it as the countenance was too green. Mr. Freshwater said the work seemed to follow on the lines worked by Ives, Sanger-Shepherd, Leon Vidal, and others. Mr. Hart showed a postal box for negatives, where the negatives are held by rubber pads, and said boxes are made for various numbers of negatives. Mr. Freshwater opened the discussion on collodion-chloride papers, and showed strips of Paget and Aristo self-toning paper, 1st, unfixed; 2nd, washed; 3rd, salted and fixed. He had also tried them toned, and thought the Aristo stood it best. He also showed prints on Paget, Crossed Swords, Kodak, Seltona, and Valento papers which he had toned to purple, which he said he had no trouble in getting. Mr. Wills passed round prints on the same papers toned with gold and platinum, and said he thought the reduction very great. Mr. Rapson showed prints on Aristo and Paget self-toning papers, 1st, fixed only; 2nd, washed; 3rd, immersed one minute in salt bath; 4th, three minutes salt; 5th, five minutes salt; 6th, toned in sulphocyanide and gold bath. In his hands the Paget paper had given a warmer tone throughout than the Aristo. The matt papers stood the toning well, but with the glossy papers the effect was disastrous. He also passed round prints on the other samples of C. C. paper toned with sulphocyanide and gold with a long range of tones from sepia through browns to deep purple. Mr. Haddon said the scale of tones was shorter in the C. C. than in the gelatino-chloride papers, but prints could be left longer in the fixing bath without loss of density. He found that Crossed-Swords paper required very deep printing, and showed prints toned with platinum and formate, and gold and formate, with a range of deep browns and blacks. He thought the paper difficult to mount on account of its curling at the edges, but it was pointed out that if the precaution was taken of having the first washing shallow and keeping the prints well pressed down for five minutes, there was no further tendency to curl. Mr. Teape spoke of the variation in the strength of the fixing baths recommended, they bring 1 to 20, 3 to 20, and 4 to 32, and thought the weak bath would leave the prints very liable to fade. He showed prints on Paget C. C., toned one with gold and the other with platinum, and on Crossed-Swords C. C., one toned with platinum and another with gold to brown only, which, when dry, were both equally black. Also a number of prints on the various makes of C. C. papers with good brown and black tones. His experience with Paget self-toning was different from Mr. Rapson's, as his all gave cool tones. Mr. Henderson suggested that the difference was possibly due to the fixing baths used. Mr. Teape said his was made alkaline with ammonia. Mr. Hodges showed prints on Kodak, Solar, and Diamond C. C. papers, all toned with gold followed by platinum, which were a very rich black. Prints were also shown by other members. It was mentioned that the bronzing on C. C.

papers was a different colour to that on albumenised papers, being golden colour instead of green. Mr. Teape said the bronzing would be removed if the prints were allowed to remain for a longer time in the fixing bath. The general opinion was that the whole of the papers were easily worked, and great range of pleasing tones were obtainable once the individual idiosyncrasies were noted. Mr. Mackie showed several samples of gelatino-chloride paper which had gone green through keeping in a box with celluloid films, the emanations from which, he thought, had caused the change. He also showed a bromide print which had been toned brown with sulphur, one half had then been again toned in a sulphocyanide and gold bath and turned red. The chairman then presented the bronze plaque to Mr. Hodges, which he had won in the Affiliation of Photographic Societies' Second Lantern-Slide Competition. On October 6, Mr. A. L. Henderson will give a lantern lecture on Constantinople.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION—EDINBURGH BRANCH.

A meeting of the above was held at 38, Castle Street, Edinburgh, on Friday, September 16.

Present Messrs. Balmain, Bibbs, Young, Pursey, Salmon, and Moffat, hon. sec. Mr. Salmon occupied the chair.

An interesting discussion took place on "Studio Lighting." The general opinion was in favour of a slightly slanted high-side lighted studio, glazed with ground glass, with blinds from the top and bottom. Any effect could be got by placing the subject at various distances from the light; also by using a concentrated light, or, otherwise as the case required.

One member suggested that buttermilk dabbed on to plain glass was a good substitute for ground glass.

Mr. Snowden Ward's proposition to reorganise a new benevolent fund was next discussed. The members agreed to support a benevolent society, if started by the P.P.A., or the R.P.S., in London.

Certificates to qualified assistants.—This was thought to be a move in the right direction, if it could be arranged. It would be necessary to grant certificates for the various branches of photography; such as operator, retoucher, printer, etc. This, of course, would not prevent anyone from having a certificate for each branch.

With regard to operator, it was thought there might be some difficulty, as so much depended upon manner and the gift of putting the subject at their ease. An employer's testimonial would be more valuable than even a certificate in this case. It was agreed that it would be a decided boon to have certified assistants, would save trouble and weed out incompetent men.

A vote of thanks to the chairman terminated the proceedings.

Commercial & Legal Intelligence

METATYPE Company, Limited.—The above-named company has been registered with a capital of £4,000 in £1 shares. Object to acquire, exploit, and work the patented process of metatype plaques, papers, and plates for photographic or other purposes, to take over the business hitherto carried on by H. Ahrlé, and to carry on the business of photographers, artists, etc. No initial public issue. Registered without articles of association.

EXCELSIOR Photographic Company, Limited.—The above-named company has been registered with a capital of £1,000 in £5 shares. Object: To adopt an agreement between F. E. Jones and G. A. Jones of the one part, and C. Sutcliffe of the other part, for the acquisition of the business carried on by the said F. E. Jones and G. A. Jones, and to carry on at 17, King Street, Carmarthen, and elsewhere in the United Kingdom, the business of photographers, photographic and fine art publishers, picture frame makers, etc. Minimum cash subscription, £250. Registered without articles of association.

BASSANO, Limited.—This company has been registered with a capital of £5,000 in £1 shares. The objects of the company are to acquire the business of photographers and photographic miniature painters carried on at 25, Old Bond Street, W., as Bassano Studios, Limited, and to carry on same, together with the business of dealers in photographic sundries, publishers, and printers, etc. There will

be no initial public issue. The first directors (to number not less than two or more than five) are to be appointed by the signatories. No qualification required. Remuneration as fixed by the shareholders.

CHISLEHURST Caves: Expensive Advertising.—Blyfield v. Ryan. At the Bromley County Court last week, plaintiff, a photographer, Chislehurst, sought to recover of the defendants, who are the proprietors of the Bickley Hotel, the sum of £57 13s., balance of account for the supply of three show-cases for advertising the Chislehurst Caves. Mr. H. M. Givens was counsel for the plaintiff, and Mr. Profumo, barrister, appeared for the defendants. Mr. Givens, opening, said this, a remitted action, was to recover the balance of an account for show-cases supplied to defendants' order. There were but three items in dispute, and the question was as to the amount that ought to be charged for the cases. Plaintiff carried his business as a photographer artist, and her husband managed the business. Defendants were the proprietors of the Bickley Hotel, and he believed they also owned the Chislehurst Caves, from which they made considerable profit. In the autumn of last year the defendant, Herbert Ryan, came and ordered some show-cases. The show-cases were to contain photographs of the caves, and plaintiff was to supply them. The cases were for the purpose of advertising the caves, and plaintiff was told that they were to be good and large. No price was fixed. Plaintiff, in accordance with this, went and took photographs of the caves, which occupied him some very considerable time. The show-cases he had to buy elsewhere. The photographs, of course, were photographs which had to be taken underground, which resulted in the spoiling of a lot of negatives. In the end, plaintiff supplied three different show-cases, and thirteen original photographs. They were finished in the spring of this year, and some payments were made on account. £28 was paid before the action was commenced £17 13s. had been paid into Court, and the amount now in dispute was £40. Application for payment had been made from time to time, but without success. Plaintiff's husband, in bearing out counsel's opening statement, said the show-cases were ordered for the purpose of advertising the Chislehurst Caves at different railway stations. He considered that he was entitled to £2 2s. for each of the original negatives. He also had to go to the different places to arrange about the fixing up of the case. After supplying one case, the defendants ordered two more. He had made a charge for taking the photographs, for the printing that had to be done, as well as what he bought for the show-cases. He charged 3s. 6d. for duplicate copies of the original negatives. In the course of the work he saw the defendant several times, but they never complained about the price. He paid over £30 for the show-cases, and another £3 for smaller items. This did not include anything for the labour of taking the photographs and putting them up. Corroborative evidence was given by Mrs. Blyfield. The photographs were taken entirely for show-cases, and not for letter-cards or postcards. Herbert Ryan, the proprietor of the Bickley Hotel, said in the autumn of last year he had thought, in conjunction with Professor Nicholls, that it would be advisable to have some photographs taken of the caves. Postcards and letter-cards were ordered of the plaintiff, and for these he paid £45. When he gave the order for these photographs, he never dreamed of having show-cases. He had the photographs for the purpose of distributing them amongst the members of different archaeological and geological societies, and to sell. He paid £28 on account before he received any account for the show-cases, and he now thought he had already paid enough for the work. It was not till recently that he found out that he was being robbed. His Honor said he could not give more than an additional £10. He was giving the plaintiff the benefit of a good deal that he ought not to give him, perhaps, but he held that the photographs were taken by him for the show-cases. Judgment would be given for an additional £10 and counsel's fee.

BALLOON Photographs of Alps.—Captain Spelterini for several hours during his recent balloon ascent over the Alps had splendid weather and was able to photograph the Jungfrau group, the Blumlisalp, the Breithorn, and the Wildstrubel. A thick fog afterwards prevented him from taking his bearings. The maximum height reached was 20,000ft., the temperature being then 9 degs. (Fahr.) below freezing point.

News and Notes.

Mr. Thornton-Pickard Manufacturing Company's £100 cash prize competition closes to-morrow (Saturday), October 1. Those of our readers who intend competing and have not yet sent in their prints will do so to-day.

Is Radium Taxable?—Customs officials in the United States have decided whether radium is taxable. Hitherto they have imposed 5 per cent. ad valorem duty, but the principal importing firm now contends that radium is a crude mineral, and must be admitted free.

Borough Polytechnic Photographic Society.—This society opens its winter session on October 7. The practical instruction and lecture evenings will be held each week as usual. The society has four dark rooms and an enlarging room. Particulars of membership can be obtained from the Hon. Sec., 103, Borough Road, S.E.

Owing to the increased business of the photographic paper department of the Rotary Photographic Company, Limited, they have found it necessary to appoint Mr. Charles J. Miller to relieve Mr. W. A. Sims of the business management, Mr. Sims continuing the technical (including demonstrating) of the above company.

Entry forms for the Braintree and Bocking Camera Club's Second Annual Exhibition are now ready. Entries close on October 31. There are five open classes, and silver and bronze medals are offered for each. The Rev. F. C. Lambert, M.A., is the judge. Full particulars are obtainable from the Assistant Hon. Sec., W. H. Hon, 81, High Street, Braintree, Essex.

L.P.S. EXHIBITION.—The following lantern lectures will be given at the New Gallery, Regent Street, to-morrow and next week:—Monday, October 1, "Photographic Studies of Marine Life," by Martin Duncan; Monday, October 3, "Submarine Boats, Past and Present," by Alan H. Burgoyne, F.R.G.S.; Thursday, October 6, "The Sculptures of Chartres Cathedral," by Ernest Marriage, L.P.S.

Every lover of breezy sea pictures will hear with regret of the death of Mr. Colin Hunter, A.R.A., who contrived to get into his work so much of the real dignity of the ocean. He was born in Glasgow in 1841, and was brought up within sight of the picturesque ruins of the Firth of Clyde, for his father was postmaster of Helensburgh. When he left school he was made a clerk, but his native talent enabled him in a few years to break out of this distasteful career, and in time he became the most faithful and characteristic painter of Scottish sea-scenery. He was elected an Associate of the Royal Academy in 1884.

Picture Postcard Problems.—The postal administrations of the world are at loggerheads on the subject of picture postcards. Adding written or printed matter on the same side of the card as the pictures is the great bone of contention which apparently nothing less than an international postal congress can settle. England began the movement by insisting upon the address and the written matter appearing on opposite sides, but for internal cards only accepting cards of the contrary arrangement from foreign countries. Belgium, however, surtaxes as letters postcards having the written matter and the pictures on the same side. Now France, owing to the simply enormous growth of the picture postcard traffic, has brought the subject before foreign Governments, and it will form one of the most important items of next year's international congress.

HEFFIELD Photographic Society.—A meeting of this society was held at the Builders' Exchange, Cross Burgess Street, on Tuesday evening last. A lecture was delivered by Mr. James R. Wigfull, I.B.A., on "The Norman Churches of Workop and district." The lecturer, in his opening remarks, described and compared Norman architecture with the Saxon work which preceded it, his illustrations of the latter work being drawn from the churches of Deerhurst, Ford-on-Avon, and Laughton-en-le-Morthen. By means of plans and views the history and characteristic features of the churches of Workop, Steadly, Thorpe Salvin, Edlington, and Laughton-en-le-Morthen were dealt with, the original Norman work and the alterations and additions thereto at later periods being described in

detail. The value of the lecture was enhanced by a series of upwards of 100 lantern slides prepared by Mr. Wigfull.

WE have recently had the opportunity of inspecting a series of portraits and other studies by the well-known photographer Mr. Will Parsons, of 147, North End, Croydon. Mr. Parsons comes of a photographic family long located at St. John's, Newfoundland, the oldest British Colony. His photographic career commenced in New York, and he has since worked in portraiture and photographic engraving in London, Leeds, and Manchester. But his chief direct photographic experiences were gained with the renowned firm of Elliott and Fry (London). Besides studio portraiture of a distinctly original and artistic kind, Mr. Parsons particularly devotes himself to a class of work which we have so long advocated in these columns, viz., at horse-portraiture. In this branch of work Mr. Parsons is distinctly successful. He has located himself in a typical English centre, where work of the kind which he undertakes will be sure of every appreciation, and we are confident that he has the ability to succeed, and assured that he deserves to.

DEATH of Professor Finsen.—The death is announced of Professor Niels Finsen, the inventor of the light treatment for lupus which bears his name. Professor Finsen was in his forty-fourth year, and his great invention in therapeutic science first became known in this country mainly through the instrumentality of Queen Alexandra, who presented a set of the Finsen apparatus to the London Hospital. There is now a large instalment of the light in that institution, and medical men bear testimony that many patients suffering from a distressing and disfiguring disease have derived incalculable benefit from the treatment. Dr. Finsen used the violet and ultra-violet rays, employing a very ingenious device for absorbing the red light. His idea was to expose the bacilli in the skin to the destroying effect of the light, thus removing the cause of disease. For small-pox he excluded the chemical rays of light by the use of red curtains and red blinds. This avoided the fever caused by the rays acting on the diseased and irritated skin, as well as the disfiguring marks, without the necessity of keeping the patient in a totally dark room. Small-pox rarely occurs in Denmark, but the professor always insisted upon the great boon which a general introduction of the red light would confer upon the numerous sufferers in this country.

RECONSTRUCTING History with the Aid of the Cinematograph.—By some occult influence a firm of biograph or cinematograph manufacturers managed to secure permission to operate in the grounds of the famous Palace of Versailles, writes the Paris correspondent of the "Express." At nine o'clock on Friday morning the party arrived, with a hundred supernumeraries dressed in costumes of the time of Louis XV. The omnibuses containing these people were rapidly driven into the park and the gates closed, so that the public should not know what was going on. Some of the ancient Louis XV. carriages had been brought from the Trianon for the purpose of the masquerade, and, with the Palace as a background, a scene representing Louis XV. and his courtiers watching a ballet or divertissement was cinematographed. To add to the effect, the magnificent fountains, which are only allowed to play on special occasions, were set to work. The party then proceeded to the famous Colonnade Grove. In the beautiful marble bath with its fountain a number of women in the scantiest costume were cinematographed as a group representing Proserpine being carried off by Pluto, the women representing water nymphs. Next they proceeded to the spot known as Apollo's Bath, and here a scene of a scandalous character, supposed to have taken place in the presence of Louis XV., consisting of the duels fought between women, was cinematographed. The entire proceedings lasted from 9 a.m. until 4 p.m., during which time the public were excluded from the Palace. At four o'clock the motley company of costumed people returned to Paris. The affair has caused considerable commotion at Versailles, but the curator of the museum and the architect of the Palace were powerless to interfere, having received orders from a high State official. Inquiry was made at the office of the Ministry of Public Education, and it was stated that the firm of cinematograph manufacturers were given the necessary authorisation on their representation that they desired to reconstitute scenes of historical interest for the benefit of public school children. It is hardly likely, however, that the scenes taken in the Colonnade and Apollo's Bath are intended for the education of children.

INVITATION SITTINGS.

To the Editors.

Gentlemen,—On reading Mr. T. C. Turner's letter, which you print in to-day's issue, I turned at once to my letter published on the 16th to see if anything I had said could possibly be construed into advocacy of the "invitation sitting" system. I find nothing. I recognised that there were a large number of invitation sittings; who could fail to do so? My whole point was that any support the B. J. had given and would give to the professional in the matter of copyright might be diminished in value by an apparent complaint when it had had to pay.

Mr. Turner's expressions are very strong, and, as they are in the nature of a reply to my letter, become almost a personal attack. May I then claim the right to say that, though working in a neighbourhood where the practice of inviting sittings very indiscriminately has been carried on by several men or firms (two of whom I am glad to say have recently had to close), I have not invited any sittings, except in the case of one or two friends of whom I have wished to make portraits for other than commercial purposes, and have always opposed the suggestion when it has been made to me by those who thought they knew my business better than myself.

I think, however, the second paragraph in my previous letter is sufficient to show that I am not one of "the fellows who are damning the future of professional photography." My experience is that the practice of inviting sittings causes as much "irritation and distrust" amongst the public as it does amongst professionals and the press. One continually hears the comments of clients on the matter—Yours truly,

C. H. HEWITT.

The Rembrandt Studio, Gateshead-on-Tyne
September 23, 1904.

[The last sentence in the first paragraph of Mr. Hewitt's letter reiterates a former misapprehension of his. We made no "complaint" at "having to pay," as our correspondent can inform himself by carefully and intelligently reading our original append. What we did was to point out, and illustrate from our own experience, a flaw in the invitation sitting system for the benefit of those who follow that method of business. This correspondence here terminates.—Eds.]

THE INCOME TAX RECLAMATION ASSOCIATION.

To the Editors.

Gentlemen.—The annual report of the Commissioners of Inland Revenue has lately been published, and press and public have generally assumed that the contents thereof reveal national prosperity. This assumption appears to me to be erroneous.

I hold this view because the figures of the Commissioners of Inland Revenue showing gross or net income are not a just basis for measuring national prosperity.

The following reasons will amply demonstrate this fact although additions might easily be made:—

The statistics do not take into account losses of income.—The profits of ten firms making £1,000 per annum would give an income of £10,000; the loss of £1,000 per annum by each of ten other firms would counterbalance this total property, but the national income would still be called £10,000 by the Revenue authorities.

The statistics do not take into account losses of capital, e.g., a coal or other mining concern may spend a quarter of a million and reap no benefit owing to failure to develop mineral in payable quantity. Again, another firm may make a similar total expenditure and develop a rich mine and in the course of years recoup its capital expenditure in the profit of working. All such profit, however, is assessable to income tax without any deduction for redemption of capital. The same principle is involved in the case of annuities purchased, every pound of so-called income proceeding from which includes a repayment of the sunken capital.

The incidence of the income tax likewise embraces items which

cannot be deemed profit from a commercial point of view, preliminary expenses, various depreciations, etc., which in all soundly managed concerns are treated as deductions from gross revenue.

There are but five schedules under which income tax is collected, and of these, schedule A assessments embrace unproductive lands, parks, and woodlands, together with public buildings from which actual income is derived.

Under schedule B profits are estimated by an artificial rule, one-third of the annual value under schedule A without reference to the actual profit or loss (usually the latter) resulting from agricultural operations.

Schedule C:—The aggregate of incomes derived by residents of the United Kingdom and assessed here under this schedule assumes a very large total. Hence an increase may be a sign of decadence of national prosperity.

Schedule D:—Under this schedule there are also large assessments upon concerns carried on abroad but assumed, for revenue purposes, to be managed from this country. Moreover, although the gross income under schedule D—the commercial schedule—increased by 8 per cent., the average increase of population is over 1 per cent. per annum. This fact alone negatives the view of prosperity—assumption.

I have made inquiry of many house and estate agents whose observations are naturally of great variety; from them I learn that the almost universal tendency is towards retrenchment, which would suggest forcibly that the increase of personal incomes is of the stuff of which dreams are made of.

If, in fact, the "increase is non-existent" it might be advantageously remembered that a repayment of tax should be insisted upon in addition to which repayment the sufferer by an actual loss should reclaim the tax thereupon as well as an abatement if his total income has been reduced to or below £700 per annum.—Yours faithfully,

T. HALLETT FRY,

Manager, The Income Tax Reclamation Association,
14, Queen Victoria Street, London, E.C.
September 23, 1904.

MODERN COMPETITION AND THE FUTURE OF PHOTOGRAPHY.

To the Editors.

Gentlemen,—Since writing letter published in your April 22 issue on "Modern Competition," in which I affirmed that "the times years ago were better than these for the photographer," several letters have appeared in your valuable paper (which it has been my privilege to read from its commencement) concerning the practical conditions, present and future, of photography. I have read these with great interest, and, without wishing to make any invidious distinction, cannot but feel that Mr. Arnett, in your issue of September 2, puts the case all round in the clearest light as regards both employers and employees. There is one phase, however, which tends to the production of mediocre work and the consequent satisfaction of mediocre workers, viz., the tendency to buy in the cheapest rather than the best market. The cause for this, as far as photography is concerned, may be illustrated by a little incident in my own experience about five years ago. A certain tradesman, wishing to introduce the sale of photographic views, and knowing something of my work, asked me to call upon him. I did so, when he inquired my prices for the different sizes. In reply to my quotations, he said, "But I can buy them much cheaper." "Probably you can," I remarked, "but of the same quality." "Unfortunately," said he, "there are many buyers than judges of good work." So, not being disposed to cut prices to obtain his custom, I wished him "Good morning."

To this day my prices remain the same, but I hope the standard of the work is still higher. I believe my would-be customer bit his fingers by buying some cheap stuff. I should say serve him right. Though it may cost us something, it should be our aim to educate the public to the appreciation of what is good and artistic, and get them to realise that the best, though dearest, is, after all, the cheapest. As an old wet-plate worker, I agree with Mr. Arnett in thinking "that the simplified methods should have resulted in rising the quality of the work to a higher standard, both technically and artistically. But, technically, I am still inclined to think the wet plate has the best of it. I have handled these in all sizes, and am bound to say that the operator can work to a greater nicety with all kinds

atives when he has all in working order. This reference to the just reminds me of one whose death you have so recently recorded, from whom in early days we used to buy photographic glass at the I expect the present generation would think they should get plates for. I refer to Mr. Forrest. But I have digressed a little. at about the future? Can assistants' wages be raised amid all cutting of prices and competition with dealers not really in the e, for one branch of the business should keep another, and the ng part is of great importance, or should be? By that I mean ographers in provincial towns at least should have a selling depart- of some kind as an adjunct to the working. My observation has me to the conclusion that those who have to depend entirely on own work never make the headway financially that those do are able also to sell the work of others; but this means, of course, capital, and when a photographer thinks of extending in this tion he is at present met with some hindrances that did not exist years ago. This, with your kind permission, I may more fully in later on.

st one word on another topic. I noted you asked for comments e question of buying stale plates of a local dealer, and its con- chases, etc. My experience has taught me never to risk it for ing special—Yours, etc., OLD PROFESSIONAL.

ptember 27, 1904.

New Book.

rbuch für Photographie und Reproduktionstechnik." 1904. Dr. Josef Maria Eder. Published by Wilhelm Knapp, Halle a/S. Dr. Eder had no other claim upon photographers for their in- dness in promoting the welfare of their art, the Jahrbuch would ore than sufficient as a lasting memorial of his services. The uch is looked forward to by many persons as a record of the ace made in all branches of photography during the year, and olume now before us is not less interesting and important than f its predecessors. It is only possible in the space at our com- to indicate the contents of this volume of about 650 pages, but alue of it may be estimated by the names of the authors of the al contributions:—Baron von Hübl, Dr. Hartmann, Dr. o-Cramer, Professor K. Kruijs, Messrs. Lumière and Seyerwitz, R. Neuhauss, Dr. R. Abegg, Professor E. Valenta, Dr. M. esen, Professor Namias, J. Gaedicke, and many others. The and improved apparatus of the year is also brought under review, ere will be found the description of some new forms of lenses. r the heading of Messrs. J. H. Dallmeyer's Stigmatic Portrait e notice an obvious mistake. Our notice concerning the more e series for hand-camera use, given in this year's "British al Photographic Almanac," page 943, has been misinterpreted. e made to say that Messrs. Dallmeyer have increased the aper- of the stigmatic portrait lens to f/4.5. It should be generally n that standard aperture of this lens is f/4, and we believe it has been reduced, not increased, to f/4.5 in these hand-camera lenses e sake of portability, to which end the mount is also made of alium.

e specimens of photographic illustration at the end of the volume eerve more than passing attention. We find among them another e Miesche's three-colour pictures, which have aroused such wide- d interest.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject e approval of the Publishers, and advertisements are inserted ely without condition, expressed or implied, as to what appears in at portion of the paper.

G. AND SON.—We know nothing of the firm referred to.

J. C. W.—Better address Messrs. Thorne and Hoddle, Westminster, S.W.

J. PALMER CLARKE.—A list of all forthcoming photographic exhibitions is published every week in the Journal.

F. G. STEGGLES.—The address of the secretary of the Royal Photographic Society is 66, Russell Square, London, W.C.

"S. E."—The paper you mention is made by The Paget Prize Plate Company, Watford. It is a "gaslight" gelatine paper, and is known as "Gravura." The Kodak Company's Egg-Shell matte "Dekko" paper is a similar production.

SPOTTING COLOURS.—"ANXIOUS" asks: "Is there any colour used for spotting P.O.P. prints that will retain the prints still glossy? If so, where can it be obtained?" In reply: Spotting colours, specially prepared for the purpose, are supplied by all the large dealers.

ADDRESSES WANTED.—H. WEST writes that he would be glad of a few names and addresses of houses supplying mouldings and ready-made frames, also cut mounts. In reply: If you will take the trouble of consulting our advertisement pages you will see the addresses of several houses supplying what you require.

COLLOTYPE PRINTING.—SYDNEY BARTON asks: "Will you be good enough to give the names of one or two good German colotype printers for postcard work?" In reply: We only know the addresses of English colotype printers. We should advise you to ask some of the German journals for the addresses of German ones.

DIRECTORY OF PHOTOGRAPHERS.—"A. B. S." writes: "Will you kindly inform me if a Directory of Photographers, or Directory of Photographers in London, exists, in which photographers are classified into, for example, portrait photographers, architectural photographers, press photographers, and so forth." In reply: No such directory is published.

DEVELOPER.—J. BROWN says: "I shall be glad if you would kindly publish a good cheap bromide developer; one that will give a nice rich grey tone. I have tried several but get a greenish tint from them." In reply: We should advise you to employ the developer recommended by the makers of the paper you use. A developer that may be the best for one paper may not be so for another. We suspect the greenish tints you get are due to under exposure, or the use of too much bromide.

RETOUCHING CELLULOID.—"W. T." says: "(1) Enclosed you will find two prints for inspection. Please state if my retouching is satisfactory for the short time it is done in—thirty minutes. (2) Could you advise me how to celluloid some small P.O.P.

prints after tinting?" In reply: (1) We can give no opinion on the work as prints from the untouched negatives were not sent for comparison. (2) The celluloid is attached by soaking the prints in methylated spirit and then rolling them in contact with the celluloid with a heated heavy roller. Appliances for the work are supplied by Fallowfield.

FINISHING ENLARGEMENTS.—B. CLOTHIER says: "I have been working up enlargements with ordinary black stumping chalk bought at pictures and artists' materials shop, but find the chalk turns brown with rubbing on paper. Could you tell me of anything better that I could use? They are cheap enlargements, and I have to do a quantity, and I want a good blue black, as the brown looks rather bad, and will you tell me if chalk is the quickest method of working them up?" In reply: We should advise you to get another and blacker chalk. Such are supplied by artists' colourmen. The air-brush is probably a quicker method of working.

STAINED ENLARGEMENTS.—"TRADE" says: "I should be greatly obliged if you would give me your opinion on the result of the enclosed print as to the tone, making special note on the colour of the paper. The enlargement is made from an amateur film (Kodak) on Morgan and Kidd white bromide paper; developed with metol-kinone, and toned exactly as recommended in your issue of the 9th September. Should not the paper be much whiter? The washing was very thorough after the bleaching." In reply: The stain is clearly due to incomplete washing between the operations. If you read the article again you will see that great stress is laid on the copper being thoroughly removed, or stains, such as you have got, will result.

PANORAMA.—H. JACKSON says: "I am going to photograph an expansive valley, for which I shall require three or perhaps four negatives. I should like to combine them all into one picture. Could you give me the best method of doing this neatly? Could it be done by joining prints up, and, if so, how, or is there any other way of getting all on to one piece of paper? I should be pleased for full particulars through your journal." In reply: The space available in this column is much too limited to give full particulars of the different methods of joining a series of pictures to obtain a panorama. However, if you take the negatives one after the other without moving the camera from its position, simply rotating it on the stand, and giving the same exposure for each, you will have little difficulty in neatly joining the different sections.

BROWN STAIN ON NEGATIVE.—R. NIMMO says: "In order to obtain a hasty print from a 1-1 'Sovereign' plate, I just rinsed the latter after fixing, and placed in printing frame in contact with a piece of Ilford P.O.P. After printing in direct sun's rays paper was removed, and where it had touched surface of negative it has produced a brown stain. The developer was pyro-soda. Have tried to remove stain by immersing the plate successively in the following solutions, washing well before and after each trial: (1) Weak solution of citric acid. (2) Weak solution of ammonia. (3) Weak solution of hydrochloric acid. Neither of these affected the stain. I shall be glad if you will kindly suggest a remedy." In reply: By printing from the plate in the way you have done nothing but a spoilt negative could be expected. We do not think you will be successful in removing the stain. You might try a long soaking in a fresh solution of hypo. The best thing, however, to do is to take a new negative.

VARIOUS QUERIES.—"G. A. W." writes: "During the last few weeks there has appeared in your columns a reference to some booklet, which is illustrated by good photos or something of the kind which I wish to procure, and which you advised readers who were at all interested to get one, and said that one could be had for the asking. I am now unable to find the reference. Can you help me by either giving me the name of the booklet and the address from which it is obtainable, or refer me to the date of the issue of 'The Journal' and page of same? 2. Can you offer any suggestions as to what is the best method of photographing silver goods, and all highly-polished surfaces?" In reply: 1. We must, in the most courteous manner, decline the task of guessing the puzzle our correspondent has set us. If he does not know which is the "something of the kind" he has in mind, how should we? 2. Proceed as for any other branch of photo-

graphy, but back your plates; use a small stop; and the surface of the objects with mutton fat or putty.

REFLECTED IMAGE.—"A. F. P." sends us the following letter, it is amusing we print it in its entirety: "I am taking liberty of sending you prints from a negative which has left with me by a gentleman who would like your opinion to the cause of the strange markings in the picture which is hanging on the wall. You will notice that the things have a resemblance to a pair of skeleton hands playing piano, and if you closely examine the enlargement which I made, you will also see the appearance of a shadowy figure on the back. There had been considerable friction with the occupants of the house next door owing to the continual coming of their piano, which was just through the thin wall, and which was being well thumped during the evening of the plate. The young lady who took the photograph therefore considerably startled when she discovered the picture image she had developed, and the closest investigation had to account for the strange effect. The picture itself is an ordinary half-length portrait." In reply: There is no mystery in the matter. The markings are caused by reflections of things in the room on the glass. You see there are reflections on the other pictures.

SPOTTY PRINTS.—E. WOODCOCK writes: "I shall feel greatly obliged if you will kindly let me have your opinion of the cause of the spots on enclosed prints. I have been troubled for some months with this kind of thing, and half the orders have to be printed on ordinary commercial C.C. of, I believe, the best manufacture, although purchased in London. The instructions have been most carefully carried out, and every precaution taken to guard against a repetition of this nuisance, and prints have been well washed by hand in forty char water for two hours. Is it possible the quality of hypo might be at fault? but, if so, that does account for the trouble with C.C. only. My bromide enlargements, Velox prints, and other kinds of paper being perfect. I have, however, experienced the trouble with five different makes of C.C. reprints. They are fixed in hypo 1-20 for twelve minutes. I may as well say I am a professional photographer of twenty years' experience, and a chemist. Your valuable opinion will be esteemed." In reply: As our correspondent says he is a photographer of twenty years' standing, and a chemist, and he doing the work cannot detect the cause of the trouble, we are afraid we must do so by simply looking at a couple of prints. As he has five different brands of paper it is clear that the paper is not at fault. Some of the spots are obviously due to air bells as to the paper while in the fixing bath. The others are probably due to particles of pernicious matter, as dust, coming in with the prints while they are wet.

RIGHT TO PUBLISH.—"INGLE NOOK" writes: "Some three years ago a customer photographed an old fashioned fireplace at a house tenanted by a woman. She gave every facility for the picture, providing accessories, etc., and two farm boys volunteered to pose beside the hearth. The picture, entitled 'The Ingle Nook,' and it has been published in various papers, besides having a moderate sale as a print, and during the past season as a post-card. Now the tenant of the place has written the following note:—'Dear Sir,—I write to say that I have more photographs or post-cards sold of my kitchen fire and I also wish the negative destroyed.' No reason is given for this demand, and my customer can only conjecture that the request is inspired by some other photographer who has also taken the view and wishes the monopoly of it. The question arises: Can the woman recall the gift of copies given over three years ago, namely, the privilege of taking the picture of the fireplace? No 'valuable consideration' was given for the permission except copies of the photograph, which she has complimented. Nobody is caricatured in the picture, and it is nothing offensive. There was no written right given for the picture, but this was presumptive. My customer does not intend either to cease selling the view or destroying the negative except on a legal ruling to the contrary. In the event of a latter contingency it would be disastrous to the public many interesting views, as thousands have been taken in similar circumstances." In reply: If the photographer has paid for taking the picture he is at liberty to continue to use it. We do not see how he can be stopped.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

The forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued are two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose continuing the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, the year's advances in theory and practice will be recorded.

The frontispiece of the ALMANAC will consist of a portrait study specially taken by Mr. Furley Lewis

(medallist of the Royal Photographic Society's Exhibition, 1903).

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc.

The publishers ask us to remind advertisers that a large proportion of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion, order and copy should reach them without delay.

**** IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that this year the entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1st next—a fortnight earlier than usual, so as to be well in advance of the Christmas publication season.

EX CATHEDRA.

The Dublin Convention.

A preliminary Committee meeting was held at the Hotel Metropole, Dublin, on Tuesday evening, the 27th ult., under the chairmanship of Dr. John Joly, F.R.S., the President Elect. Among those present were Mr. J. A. C. Ruthven, Mr. E. Webb Smith, Mr. H. C. Draper, Mr. Alfred Werner, Mr. H. Goodwillie, Mr. F. A. Bridge, and Mr. R. Benson (Hon. Local Sec.); considerable time being spent discussing the proposed arrangements. Those who were at the last Convention in Ireland in 1894 will not need to be reminded of the great success of the meeting and the hearty welcome accorded to the members, and when we state that the "powers that be" have made up their minds to go one better next time, we are sure our readers will await with some interest the announcement of the programme of good things in store for those who decide to go to Dublin in July next.

* * *

Science

Examinations.

We often hear of the better education given in Germany, more particularly in connection with scientific training in the different crafts, and there is little question that that country in this respect is in advance of our own. But we are advancing, for we are pleased to see that the Board of Education list of successful candidates for Royal Exhibitions, national scholarships, and free studentships (science), 1904, shows that out of the seven Royal Exhibitions five of them were gained by engine and shipwright's apprentices, the other two going to "students." Of the national scholarships for mechanics, out of the five, four of them were secured by engineers' and smiths' apprentices, and the other by an

engineering student. These high honours—and the scholarships—show that the present generation of apprentices have the interests of their craft at heart. We may fairly assume that these young fellows have not had the same opportunities of learning the theoretical portion of their craft as had those who are described as students—one of Cambridge. So much more to their credit, as they have had to get their theoretical knowledge out of their working hours.

* * *

A New Metal.

The makers of photographic apparatus, in common with other manufacturers using metals, will be attracted by reports of a new metal, or, to describe it more correctly, a new alloy, about which wonderful things are being published. This new alloy has been discovered, or fabricated, by two Tuscan engineers, and it has been patented. Possibly with a view to attract public attention, these gentlemen have christened their bantling Radium Argentiferum, and, as the name implies, it includes in its composition the common metal iron, with a certain proportion of silver and radium. We may assume that of the latter metal the quantity is infinitesimal, and probably only occurs as an impurity which cannot be got rid of. Then there is also contained in the alloy copper and phosphorus, the latter being a most important ingredient. As for the properties of the alloy, the patentees claim that it is stronger than steel, that it does not oxidise, that it conducts electricity better than copper, and can be manufactured in large quantities at one-tenth the cost of bronze. There is nothing outside the bounds of possibility in all this, and very possibly a valuable discovery has been made. But one is always suspicious when a triumph of this kind is heralded by the papers with a sensational flourish. The flourish in this case consists in the statement that during the early experiments one of the patentees, exasperated by the delay of the metal in fusing, "after hours of boiling"—we do not quite see how the stuff could boil without fusing first—threw his last two-franc piece into the crucible. "The result was a revelation." But what it revealed, whether the crucible boiled over, or left off boiling, or began to fry, or to stew, or to roast, or to bake, we are left in complete ignorance. The attempt to explain technical processes in sensational paragraphs is a feature of the modern newspaper, which generally fails in its object.

* * *

Certificates to Assistants.

Apropos of the note *re* "Science Examinations," the Professional Photographers' Association is considering the question of the granting of certificates to qualified assistants, and a somewhat knotty one, we imagine, they find it. But it is being duly considered both by the headquarters in London and by the provincial branches. The question was brought forward at the last meeting of the Edinburgh branch, and duly discussed, as it has been at other branches, but no definite conclusion was arrived at. Here are one or two points which, it seems to us, will have to be taken into consideration. For example, operators, printers, etc., may be capable of turning out, in practice, excellent work, but yet know nothing theoretically of the subject. Some, on the other hand (and they are the fewer) have a thorough theoretical knowledge of it and its chemistry, but are of very little value in actual practice. It is pretty well known that some of the best photographers, both employers and employees, have little or no theoretical knowledge of the processes they employ; yet they produce excellent work. Therefore, on what basis are the certificates to be granted,

so that employers are to be ensured that they are engaged proficient hands? There can be no two opinions, in case of a printer, that if he has a complete knowledge of the chemistry of the different printing processes, and at the same time a good practical worker, he is, or should be, a more valuable hand than one who does not possess that knowledge. Will that be taken into consideration granting the certificates, or will it be compulsory that an assistant possesses such knowledge? Then there is the question of operators—raised at the Edinburgh meeting in which some difficulty is anticipated, because, as we know, so much depends upon manner and the gift of putting sitters at their ease. How will the P.P.A. be able to form an opinion on this point in the granting of certificates of proficiency in studio work? However, we hope that the Association will be able to formulate such a scheme, will, to an extent at least, protect employers from engaged assistants who, while professing to be accomplished, know little or nothing of their business.

* * *

A Colour Anæsthetic.

The influence of coloured light upon the human animal organism has often formed a subject of inquiry. Certain insects, we know, are attracted by particular colours, and seem to have an aversion to others so much so that it has been found that protection from some of the biting scourges common to tropical climes has been secured by the adoption of suitably-tinted clothing. Many experiments have also been carried out in order to ascertain the effect, if any, of coloured light upon the human subject. It has been asserted that in cases of mental aberration the patient is calmed by being kept in a room in which the daylight is filtered through coloured glass. But these alleged results do not seem to have received authoritative corroboration. On the other hand, photographic workers may plead that many of them spend half their lives under the influence of ruby light without experiencing any particular harmful benefit from it. And certainly the civilised part of mankind passed much of their time, before the advent of gas and electricity as illuminants, under the feeble yellow light of lamp and candle without experiencing any unusual symptoms. Perhaps the only well-authenticated instances of a human organism being distinctly benefited by the action of coloured light are those cases of small-pox treated by the late lamented Professor Finsen, who proved most decisively that under red light patients suffering from that dreadful malady escaped the horrible scars which were at one time regarded as the necessary sequence of the disease. Now, however, a new claim is made for the benefits derived from the use of coloured light in surgery. An official report from the American Consulate at Freiburg, Germany, credited blue light with having all the virtues of chloroform without its inconveniences and danger. To quote the words of the telegram announcing this discovery, published by the "Daily Telegraph":—"The patient is shut in a dark room with his eyes exposed to the blue light. Three minutes after the exposure his teeth are extracted without pain. Despite the anæsthetic, which apparently only numbs the nerves, the patient sees and hears all the time." This circumstantial account of the discovery, coming as it does from an apparently reliable source, is certainly startling, say the least, and we shall look forward to further information with great interest. We should like to know the source of the blue light employed and to have details of the arrangements adopted by the operator. As the story stands it seems quite incredible; but we must remember that a few years ago the claims of the hypnotist to perform operations without pain would have been utterly discredited. He does not do in these days of scientific wonders to laugh readily at what seems to be impossible.

Disfigurement of Beautiful Scenery. It seems pretty evident that enterprising firms will, if they are allowed, cause a great disfigurement to our Thames.

Some time ago it was proposed to convert one of the islands facing Kew Gardens into a barge-builders' works, and unless a vigorous opposition on the part of the public had been instituted there is little doubt the project would have been carried out. Another disfigurement of the Thames is now projected. It is proposed to build a timber yard and wharf on the beautiful reach opposite Canbury Gardens. But there is, naturally, an objection to the thing, and one day last week a crowded meeting was held at Kingston-on-Thames to protest against the proposal. At the meeting a letter was read from Sir F. Dixon-Hartland, M.P., Chairman of the Thames Conservancy, stating in effect that as yet no application in the matter had been received by the Conservators, and adding that, if made, nothing would induce them to do anything to destroy the amenities of the river if it could be prevented. The Conservators are evidently bent on protecting the upper Thames and keeping it in its pristine state, and as a general pleasure resort. This is evidenced by the recent prosecutions for rowdism on the river, which in some cases has proved of inconvenience and annoyance to those with cameras. While on this topic it may be mentioned that our French neighbours are interesting themselves in the preservation of their scenery, for we read that the French Minister of Public Works has sent a circular to the State engineers which shows that, while he is naturally anxious to provide means for the development of the country, he nevertheless sympathises with the Society for the Picturesque Sites and Beautiful Landscapes. He tells the Chief Engineers that in preparing plans for bridges, etc., they should bear in mind that edifices of that sort, if judiciously placed and properly surrounded, often enhance the beauty of the spot, and that a misplaced detail frequently mars its beauty. He also requests the Chief Engineers to instruct their subordinates that, in the construction of roads, railways, and tramways, and the planting and felling of trees, etc., they should not lose sight of a proper respect for natural beauties, and should try if possible to enhance their æsthetic value. It would be well if English engineers would act on this suggestion when they are constructing a railway here, and not disfigure the scenery, as they frequently do, with hideous bridges and the like, much to painters' and photographers' disgust.

* * *

An Ice-making Machine.

The ordinary photographer does not often require the help of ice to reduce his solutions to working order, unless, that is, he is resident in India or some other very warm climate. But it is different with the plate-maker, who is during the warmer months of the year dependent upon ice to quicken the setting of the gelatine emulsion during its short passage through the coating machine. In London and other large towns and their suburbs ice can be easily and cheaply obtained, but it is different in outlying districts; and we can imagine cases in which it might be highly important for the photographic worker to be self-dependent for his ice supply. For this reason interest is attached to the description of a new ice-maker which appears in a recent consular report from Nice, to the performance of which the highest praise is accorded. Unfortunately, the report does not give the vaguest idea as to the principle upon which the machine depends for its action, and we can only assume from its description that cold is produced by the expansion of compressed air, as in the case of the large refrigerating machines employed on shipboard. We are told that the apparatus is constructed entirely of metal, and that it consists of two parts, one containing the mechanism and the

other constituting the ice-producer. The apparatus can be made in any size, the smallest now constructed occupying little more than a cubic foot of space, and producing about $4\frac{1}{2}$ lb. of ice per hour. It is worked by hand or by electric motor. The largest model made occupies four square feet of space, and with a 4-horse power motor will produce 220 lb. of ice per hour. "The ice is produced without the aid of any ingredients or preparatives of any kind. Once the machine is delivered it produces ice indefinitely, and as long as the metal-work used in its construction holds out, and this is of such a character as to last for many years." It is clear from this description that the machine does not depend for its action, like so many previous contrivances for making ice, upon the action of ether, ammonia, or sulphuric acid, chemicals which mean expense in addition to other drawbacks. Hence we assume that its action is strictly mechanical. The Consul who reports upon the machine is evidently highly impressed with its value, and he invites further inquiries from those interested in it. Any of our readers are therefore at liberty to communicate with him on the subject, addressing their letters to Mr. J. B. Cognet, banker, and U.S. Consular Agent, Cannes, France. One more quotation from the report in question we cannot refrain from making, for, unless the Consul has been very much deceived, it gives evidence of a very valuable invention: "I may add that all systems known up to the present time, and all machines existing for the manufacture of ice in a rapid and economical manner, have been compared with the one forming the subject of this report, and experts have unanimously declared this to have insuperable advantages over any of the systems and machines in question."

* * *

The N Rays. Blondlot's remarkable discovery of rays emitted by the human body, and capable of exerting an influence akin, but of much inferior power, to the Röntgen rays, has been, so far, admitted by eminent scientific men. A number of investigators on the Continent have experimented with the N-rays; the results of their investigations have been brought before the Paris Academy of Sciences, even down to the description of a spectrum of marvellous properties. But, strange to say, English scientific men, no doubt because of their traditional—on the Continent—phlegmatic temperament have utterly failed to see the rays, or to admit their belief in certain phenomenon being justly attributed to any but ordinary and well-known causes. But, still, these papers get sent to the "Academy" and printed in their *comptes rendus*. This force called "od" was discovered a century ago, and many were the effects attributed to that human radiation "odic force;" but now it is never mentioned as a serious scientific phenomenon; and, notwithstanding the photographs exhibited showing, it is stated, the undoubted effects of the N-rays, we opine that this later discovery will follow the odic force into the realms of oblivion. What would appear to be a *coup de grace* is administered in last week's "Nature" in a letter over the signature of R. W. Wood. He describes a series of experiments exhibiting, it is alleged, the N-ray effects. First an electric spark was brightened by concentrating N-rays on it through an aluminium lens. Mr. Wood could not see it, but the others could. But when they were not made cognisant of the moment when his hand was interposed in the path of the rays they utterly failed to discover whether the hand was there or not. A number of photographs, showing the brightening of the image, were brought forward, but Mr. Wood points out sources of error rendering them worthless as evidence. Next came the experiment of deviation of the rays by an aluminium prism. This was put in front of a slit in a piece of wet cardboard, and the experimenters could clearly

distinguish the spectrum spread out, and also the positions of maximum and minimum luminosity. Mr. Wood could not see all this at all, and, more than this, the room was dark, and when Mr. Wood slyly removed the prism unknown to the experimenters, they saw all the results the prism brought about just the same! When a prism is placed with its edge to the right or the left the spectrum should change accordingly. This was done by Mr. Wood, but the others could not say "which was which," "fatigue," they explained. Again: a number of circles in luminous paint were placed on the table in the dark. The approach of a file was to make them more luminous. The file was made to approach. Mr. Wood could see nothing different, but the experimenters could; and, strange to say, when Mr. Wood put the file behind his back, unknown, of course, to the rest, and moved his arm to and fro, they could see a most marked effect! Then a clock-face was to be visible when a file was held near the eyes. Mr. Wood found no difference, yet his colleague could see the face distinctly with a file, but not without, a piece of evidence not of much use, seeing that when Mr. Wood, who evidently came prepared, held a piece of wood in same shape as the file in front of the experimenters' faces it acted in the same way! All this made Mr. Wood rather sad, and he propounds a series of test experiments which would prove the question of the existence or non-existence of the rays in a perfectly satisfactory manner.

AUTUMNAL COLOUR AND HAZE.

WITH each recurring autumn it strikes one with renewed and strengthened regret that the golden yellow of the changing leaf cannot be photographically expressed in colour. Suitable sifting screens may give proper tone value, but this, although the best practicable substitute for the desired colour, is yet a very poor one. The mass of colour in the face of the wood upon the gentle slope of the hill, in the rich glow of autumnal afternoon sunlight, is quite another thing to its photographic representation. Colour and tone are very different things, and we cannot gain the best suggestion of "autumn," because our mental impress of the season is so dependent upon its characteristic colouring. But there is one marked, although, admittedly, a less stimulating feature than that of colour, in autumn, that lends itself more readily to photographic expression, and that is its mists, or, more correctly perhaps, its haze. It seems rather a reversion of function to call in the aid of photography, so eminently a clear-cut, perfectly detailed and accurately focussed an art, to express haziness. But if it can be so utilised, so much the better for the art. To the interested observer—or even, indeed, to the one who does not voluntarily observe, but who is sufficiently sympathetic in a vague way with nature to take a saunter along a country road—there is something extremely soothing, after the brilliancy of summer, in the softening effects of morning and afternoon haze in the later autumn. The world is at the same time contracted and enlarged. Contracted to the physical vision, but enlarged to the imagination in the suggestion of what may be hidden behind the indefinite veiling of the mist. In all ages human nature has accepted veiled, as infinitely more acceptable and tantalising than unveiled, beauty.

The same consideration applies when Nature veils herself in autumnal haze. Nor is there any necessity to

regard Nature in the narrower country or rural sense. The town dweller is quite as happily placed and blessed. For instance, would not a Londoner prefer his beloved river with the added suggestiveness of haze than without it? Or the dome of St. Paul's dimly seen through a haze of air than with every architectural detail showing in a clear light? Does it not look larger, more uplifted into the sky, and more of a piece with its historical and emotional place under the former than the latter conditions? There is no need to elaborate further in support of the contentions for the pleasing effects of haze, and there is no village town, or scrap of country road in which they cannot be noted and enjoyed. Their photographing is also recommended to the worker with anything of an artistic disposition, and its attendant complement of sentiment and touch of imagination. The best effects are to be gained when the sun is fairly but not too low on the horizon in morning or evening, and when the haze is not too thick. It should be at that texture at which it suggests rather than blots out. As the distant effects of haze are better than the nearer, a telephoto lens gives good results, especially when focussed upon a salient object, such as a church tower, showing above the sky line. (It is always necessary, by the way, to include some strong, prominent object to give the necessary solidity to such pictures, or otherwise they look too much like over-exposed or foggy work.) The difficulty of focussing with a telephoto lens is less a bar in this type of work, as extreme sharpness is not desirable, from its tendency to detract from the spirit of the conception. An ordinary long focus lens will also do well at nearer distances. The aperture should not be too small, as all the suggestion of space possible should be aimed for. The exposure should be fairly long, and the developer weak and restrained. But the latter is probably more a question for individual preference and temperament, for experience proves that equally good results have been got by working in opposite ways.

In all cases far better results are got in the print than one would imagine possible in looking at the negative. Probably this is due to an unconscious mental depression of the negative because it presents features directly opposite to those one is accustomed to regard as essential, normally, in a good negative. The reversal of tone, puts the all-important imagination out of court with negative, whereas with the positive it has regained field and power. The experiment of picturing the world in its garment of autumnal mist is at least well worth trying. No new appliance is needed, and if successful—and there is no reason why it should be otherwise—it will lengthen pleasure by carrying photography beyond the orthodox period of summer, and, finally, will aid in forming a high opinion of photographic possibilities, that, once gained and fixed in the mind, may lead by its indirect pressure to successful exploitation of those fields hitherto held, not from lack of experiment than anything else, as sacred to the artist.

WE have received a charming souvenir of the recent £1,000 competition organised by Messrs. Kodak, in which some of the successful photographs are beautifully reproduced.

THE SILVER "GRAIN" IN PHOTOGRAPHY.

[From the "Astrophysical Journal," by courtesy of the Author.]

II.

INFLUENCE OF DILUTION OR CONCENTRATION OF DEVELOPER, AND TIME OF DEVELOPMENT AS AFFECTING SIZE AND CHARACTER OF "GRAIN."

For this purpose a number of exactly similar exposures were made upon Seed "27" plates in the sensitometer and developed separately at the same temperature by different developing agents as follows:—

1. Rodinal. Development begun at 1:12' and continued for 15^m; successive additions of rodinal in single minims were made until the developing solution represented a strength of 1:40, taking 35 minutes more time. The 1:40 solution was then allowed to act for 10^m. Total time of development, 1^h.

2. Hydrochinone and caustic potash. Total time of development, 6^m.

3. Hydrochinone + metol + adurol + caustic soda. Total time of development, 1^m 20^s.

These negatives were then dried in a current of air, and an equal opacity square selected from which photomicrographs were made.

A comparison of the results (Nos. 8—10) shows that in the case of the slow development by rodinal the character of the grain is vastly different from that of the remaining two plates, being decidedly more "ragged" in appearance, and showing an actual and definite increase in size, principally by reason of the running together of the several particles to form a new group-particle. In the case of the plate developed with hydrochinone, the "grain" is better, with less running together, while in that developed rapidly in the hydro-meto-adurol mixture the grains of silver are seen to be deposited in a much more definite and regular form than in either of the two preceding.

These results, in the opinion of the writer, accord well with the theory of increase by accretion, in the length of development; for, according to Abney, when the silver bromide (2Ag.Br.) is acted upon by light, there is first a chemical change to Ag₂Br. (sub-bromide), followed by a physical change of the 2Ag.Br. molecules, and the blackening consists, first, of a slight reduction of Ag₂ and continues by an interaction of the molecules in which the Ag₂ seizes upon the bromine of the adjoining molecule of 2Ag.Br., and reduces that to a state permitting of reduction by the developer, while it in turn attracts the bromine of its neighbouring molecule, and so on. Second, according to Luppo Cramer, the Ag₂ ions give up their positive charge (caused by the impact of light) to the negative ions in the developer (which arise from the soluble salts in the developer), and the resulting super-saturated solution of metallic silver is deposited upon the nuclei of the Ag₂ in the film; therefore, whatever theory be preferred, it naturally follows that the longer the action of development is continued, the greater will be the size of the particle, either by interaction or deposition.

The increase in the size of the individual grains was also readily seen by developing a stained plate under the microscope. A drop of developer was applied while the 2Ag.Br. grains were under observation, and an almost immediate reduction was observed. By repeating the experiment a number of times it was seen that the grains of silver bromide, when first tested upon by the developer, were reduced as individual grains of very small dimensions,⁵ only a portion of the 2Ag.Br. particle appearing to be acted upon at first, but increasing in

size individually and then coalescing into group-particles, which become larger as development is continued.

REDUCTION OF THE SILVER BROMIDE WITHOUT PREVIOUS EXPOSURE.

That there is a definite reduction of the 2Ag.Br. particles in the film even when there has been no light impact, is well known, although not generally understood. The appearance of "chemical fog" upon the film is used by many workers as an indication of the point of maximum development.

That this "chemical fog" begins to be deposited almost from the instant of contact with the developing agent, was shown by a series of experiments as follows: Strips were cut (in darkness) from a number of plates, including Cramer "Crown," Seed "27," Seed "23," and Carbutt "Lantern Slide," and were then partially immersed in fresh hydrochinone developer for

Fig. 3.—Photomicrographs of Silver "Grain."

8. Seed 27. Rodinal, Slow Dev. (3.0 to 8 μ). 9. Seed 27. Hydrochinon, Medium Dev. (1.3 to 2.4 μ). 10. Seed 27. Hydro-Meto-Adurol, Rapid Dev. (1.4 to 1.8 μ). 11. Seed 23. Reduction without exposure. Dev. for 45 secs. 12. Seed 23. Reduction without exposure. Dev. for 10 min. 13. Seed 23. Reduction without exposure. Dev. for 20 min.

different lengths of time, from five seconds to twenty minutes, and passed immediately into the fixing bath. When dry, examination showed that reduction had taken place on all plates in amount varying according to the time of development. This reduction was relatively stronger on the "Crown" plate and weakest on the "lantern slide," the Seed "27" and "23" occupying places intermediate. The gain (by accretion) in the size of the grain particles is also very well shown in this series of plates. Nos. 11—13 (Fig. 3) give the record of the Seed "23" plate at forty-five seconds, ten minutes, and twenty minutes development, respectively. The exceeding fineness of the grain-particles in these plates will be noted, the size varying from 0.0017 to 0.002 mm. mean diameter.

This reduction of the unexposed silver bromide was found to take place with all the developing agents tested, which include hydrochinone, hydro-eikonogen, metol, rodinal, adurol, and elinol. It would therefore appear that there is present in the film a certain amount of that allotropic form of 2Ag.Br. which

⁵ This is in agreement with Liesegang ("Archiv. für Wissensch. Photo." 1, 229), who says, "Since the advance of the reduction on to the unaltered silver bromide proceeds comparatively slowly, we must conclude that it is not always necessary for the groups of particles of silver bromide to be completely reduced. In this way diminution in the size of the grain may therefore be possible."

is capable of reduction without previous light-action, and which amount increases with the sensitiveness of the plate.

The idea generally accepted by a great number of workers that the size of the silver "grain" in a negative is dependent upon the size of the grains of silver bromide originally in the film; or, by still another class, that the slow or dilute development of the plate would give a negative whose "grain" would be distinguished by a particular degree of fineness, is not borne out by the results obtained and herein specified. On the contrary, we are led to deduce from these experiments:—

1. That the original grain-particles of the silver bromide are by prolonged development considerably enlarged, by reason of the formation of group-particles, which are relatively enormously increased in size, so that a method of rapid development (provided the developer is compounded to give not too great a contrast) is the means of obtaining a more definitely uniform deposit of particles, which most nearly approach the size of those in the original 2 Ag. Br.

2. That of high-speed American plates the Seed "27 Gilt edge" is, of the four makes tested, that having the finest grain-particles, of most definite uniformity; of equal speed with the "Crown," but with less tendency to "chemical fog."

3. That the intensification of the original negative should not be attempted where enlargement is to follow.

In conclusion the writer takes pleasure in acknowledging the kind assistance of Messrs. E. B. Frost and J. A. Parkhurst in much of the foregoing work, and also takes this opportunity to sincerely thank those who so courteously replied to his communication of the spring of 1903.

ROBERT JAMES WALLACE.

Yerkes Observatory, July 4, 1904.

NOTE.

The foregoing work was begun about the beginning of 1903, at which time the author sent out a circular letter to the departments of physics and of astronomy at a number of the leading universities and observatories throughout the United States, requesting data relative to the plates and developers in general use by them. The pressure of other duties prevented the completion of the work until July of the present year.

Upon completion of the paper, and after arrangements for publication, there came to the notice of the writer an article published by Messrs. A. and L. Lumière and A. Seyewetz entitled "The Influence of the Character of Developers on the Size of Grain of Reduced Silver" (THE BRITISH JOURNAL OF PHOTOGRAPHY, No. 2,306, July 15, 1904). The method pursued and therein outlined by these eminent investigators, was as follows:—Exactly similar exposures were made upon Lumière "blue label" plates of same emulsion, which were then developed by all the principal known developers (prepared normally and also with modifications) "until the images had reached a comparable density." The portion showing the greatest opacity was then selected from each negative and by the aid of hot water the gelatine was dissolved off. "This gelatine solution, well shaken, and containing the reduced silver, was used for the preparation of material for microscopic examination." Photomicrographs were then made of the same magnification, and prints therefrom compared.

Among other conclusions thus derived, the investigators state:—

"No apparent influence is shown in the size of the grain of reduced silver by temperature, concentration, or duration of development."

An evident discordance between this conclusion and that of the present writer calls for a word of explanation. This apparent discordance would perhaps be easiest resolved if it were decided what is to be regarded as the "grain" of the negative. In the opinion of the writer the general description "grain" is taken to mean the particles of silver reduced in the negative

and in situ. It has been shown that the grain-particles of the 2 Ag. Br. are more or less modified in character, both by the method and duration of development, and the tendency of the grains to coalesce and form group-particles. A group-particle is undoubtedly formed of individual grains, but, inasmuch as their units are now to be taken collectively as a new whole, they must be so considered. Granted even that the size of individual grains remains unaltered by variation in development; yet, if a number of these particles be so welded together (as it were) by chemical or electrolytic action, their character would be altered, and hence necessitate a new consideration of their gross size.

A PROCESS OF PHOTOGRAPHIC DEVELOPMENT FOR THE PRODUCTION OF IMAGES OF FINE GRAIN.

In a previous communication¹ we indicated two developing substances—paraphenylene diamine and orthoamidophenol—which used in aqueous solutions with soda sulphite, enabled us to obtain images of fine grain and of an appearance similar to that shown in the collodion process.

In the present study we have examined, firstly, the possibility of obtaining fine grain images with developers other than paraphenylene diamine and orthoamidophenol; and secondly, have endeavoured to determine the precise conditions for the production of this special state of the silver.

Our experiments with the various commercial developers show that simultaneous realisation of two conditions is apparently indispensable to the formation of images of fine grain—viz.:—

1. Slow development, either by adding restrainers or by dilution of the developer.

2. Introduction of a solvent of silver bromide into the developer. In order to avoid solution of the silver bromide before development of the image, this solvent should not be in too large a quantity.

Chloride of ammonia appears to us to be the most suitable product to produce these conditions, using from 15 to 30 grammes to 100 cc_g of developer.

Chloride of ammonia slightly dissolves the silver bromide of the sensitive coating, and thus the developer contains a mixture of soluble silver salt and developer. Under these conditions the developer tends to reduce the dissolved silver which it contains, and we are brought back to the case of wet collodion: simultaneously with the ordinary chemical development a true physical development is produced. The images have the appearance of collodion images. In this case, therefore, it will be understood that the phenomenon arises under precise conditions. It is unquestionably necessary that there be an exact determined relation between the rapidity of the direct chemical development and that of the formation of reduced silver, the liquid in which the plates are immersed. Moreover, the effect is not produced by all solvents of silver bromide.

Paraphenylene diamine and orthoamidophenol developers, we have shown, give images of fine grain without the addition of special substances which restrain development or dissolve silver bromide, and also yield better images than those obtained by various other developers. We find that with these developers the conditions necessary for the formation of images of fine grain are supplied from the substances composing them. They have, in fact, a weak developing energy, and dissolve appreciable quantities of silver bromide. (We find that paraphenylene diamine developer dissolves 0.140 gramme of silver bromide in 100 c.c., and orthoamidophenol 0.134 gramme.)²

If paramidophenol be employed with soda sulphite under the same conditions as its isomer ortho, fine grain does not result.

¹ "Bulletin de la Société Française de Photographie," June 1900.

² A solution of soda sulphite of similar strength to that of the developers (6 cent) but containing no reducing substance, dissolving only 0.112 gramme of silver bromide.

but it must be noted that the energy of paramidophenol developer is much greater than that of its isomer ortho. If in the first the reducing power be lessened by the addition of ammonium chloride, the resulting silver grain is as fine as that obtained with orthoamidophenol.

PRACTICAL CONCLUSIONS.

The best developing formula for rapid emulsions, which gives images of normal intensity and free from fog, provided always that the plate be sufficiently exposed, is the following:—

Water	1,000 c.c.
Paraphenylene diamine	10 grammes.
Anhydrous soda sulphite	60 „

This method should be found of great interest for the development of negatives which are to be used for the purposes of enlargement. The grain forming the silver of the image being much finer than that of ordinary negatives, it should be possible to produce enlargements of greater size and with a continuous gradation of the half-tones.

With slow emulsions this new method of development should prove equally interesting, especially in the case of lantern-slides, for by its means beautiful brownish-violet tones are produced which vary according to the composition of the developer. Independently of paraphenylene diamine, in which the relative proportions of the reagents may be altered according to the tone desired, a normal hydroquinone developer may be used, to which has been added from 5 to 30 grammes of ammonium chloride per 100 c.c. of developer, according to the desired tone.

A. AND L. LUMIERE AND A. SEYEWETZ.

SOME PECULIARITIES OF DYES WHICH PRODUCE TOTAL SPECTRUM SENSITIVENESS.

Total spectrum sensitiveness is a term I have chosen for a sensitiveness that can be imparted to photographic plates which is distributed more or less throughout the whole spectrum. To produce even sensitiveness throughout to the spectrum of normal "daylight" has so far been found impossible, but it is a comparatively easy matter to extend the colour sensitiveness of the ordinary plate, in a less degree, to the red end of the spectrum without any gap at all.

The action of most dyes is quite incomprehensible, but it seems within the limits of possibility that fluorescent dyes sensitise a plate for colours complementary to their own, and that non-fluorescent dyes sensitise more or less for their own colours. This is undoubtedly a rule with a very large number of exceptions; but it certainly seems to hold good in a number of instances.

Some recent experiments with dark blackish-violet and kindred dyes have given remarkably interesting results, although they have shown themselves unsuitable for practical work in comparison with the more modern sensitisers, such as orthochrom T, etc. Two dyes which behave extremely similarly are Wool-black 4 B and Columbia-black, and these, in reference to their absorptions and sensitising actions, furnish striking examples of one peculiarity to which we would draw attention. The absorption spectra of both Wool-black and Columbia-black show that the yellowish-green rays are partially extinguished, and the sensitising action of both dyes also leads to a marked deficiency in yellowish-green sensitiveness, which is, however, only readily apparent when employing the plates bathed with them in three-colour work.

Further experiments with other non-fluorescent dyes, some of which have not—to my knowledge—been tested before for three-colour work, give rather similar results. One dye, new patent blue (Bayer's), is remarkably satisfactory from a theoretical point of view, and gives a total spectrum sensitiveness which is better than that obtainable with either Wool-black or

Columbia-black. The fogging action of these dyes is pronounced, and thus makes it difficult to recognise minima when reading the densities of the bands; it also renders plates sensitised with them very unfit for half-tone work, as it is more difficult to obtain the best differentiation in the dots.

But now, before summing up any general notes, we must consider the special case of Titan-scarlet, which, although a red dye, as its name indicates, confers upon plates bathed with it a total spectrum sensitiveness equal to any of the above-named dyes, very similar in character notwithstanding. Here, then, are a set of non-fluorescent dyes, blackish-violet in colour and red in colour, yet both produce such similar results that it is difficult to correctly ascertain the differences in their sensitising actions.

If we consider this as an exception for the moment, I certainly think it can be claimed that *all* non-fluorescent dyes produce sensitiveness to a more or less degree, and in proportion to their colour transmission powers; also that those fluorescent dyes which excite colour sensitiveness in emulsions do so in a reciprocal proportion; that is, they sensitise for the rays which they absorb, whilst non-fluorescent dyes sensitise for the rays they pass.

As regards interpreting the curves shown in Fig. 1, it must be borne in mind that they are to be compared with the sensibility curve of an ordinary undyed plate. Thus the plate is in the first instance sensitive to violet, blue, and bluish-green;

Fig. 1.

the action of the dyes is to extend this sensitiveness into the yellow and red regions of the spectrum, and very frequently to reduce the blue and violet sensitiveness originally possessed. The action of Titan-scarlet, new patent blue, Wool-black, and Columbia-black, is almost identical in each case. Titan-scarlet perhaps gives greater red sensitiveness, and this is comprehensible if the above-suggested law be true.

An examination of Fig. 2 will show that the absorption spectra of Wool-black and Columbia-black are so similar that it is difficult to detect much difference with the eye. The readings were made by means of the spectro-photometer, 1:100,000 solutions being used in a cell of 10-mm. width. The noticeable yellowish-green absorption is fully represented in the sensitising action of these dyes, as in many others tested; plates with either Wool-black or Columbia-black are remarkably deficient in yellowish-green sensitiveness. They are consequently quite useless for three-colour work, as in order to adapt a green filter to them it would be necessary to give with it an enormous exposure for the pink printing negative.

I will ask the reader to refer again to Fig. 1, where it will be observed that the ratio of yellow-sensitiveness to blue-violet sensitiveness is 1:2.19 in the case of Columbia-black, 1:2.14 in the case of Wool-black; that is to say, the ratio is almost the same, and it is so because the absorption spectra are almost identical.

A little thought devoted to the above-mentioned facts leads us to a conclusion which has doubtless been suggested before, but I leave it to the photographic historian to provide details.

This is that non-fluorescent dyes exert a screening action on the sensitive particles in the film, and that fluorescent dyes impart to the particles a screening effect which is reciprocal, i.e., the fluorescent colour is transmitted. New patent blue for example provides a "screen" through which all rays but yellowish-green pass, hence these are the rays to which the plate is least sensitive; erythrosine, on the other hand, permits the passage of greenish-yellow rays through its "screen," and thus the plate sensitised with it is chiefly susceptible to greenish-yellow. The original blue-violet sensibility is of course discounted in this consideration. When plates bathed with Wool black or Columbia-black are exposed behind the three filters used in colour photography, it is found that the ratios for the blue-violet and red exposures agree fairly well with those usually required when working with commercial plates. An exposure given for the green filter, will, with normal time give a good record of the bluish-greens, but a very feeble record of the greenish-yellows. This is only compatible with the results one would expect from the curves in Fig. 1 when one bears in mind the discount for the original blue and bluish-green sensitiveness in the unbathed plates. In commercial work, this would mean considerable re-etching of the pink "printer" or an inevitable over-redness of the resulting picture.

The method of employing an auxiliary dye is not a new one, and cannot be said to be of much value with the dyes under

ABSORPTION SPECTRA CURVES.

Fig. 2.

discussion. Cyanino blue sensitises very powerfully for red rays, when compared with Columbia black, etc., and the addition to it of erythrosine, glycine red, or chinoline red not only makes the results more brilliant and cleaner but it also makes the band of sensitiveness to the spectrum very much more even. This is not the case, however, with Wool or Columbia black, nor any of the dyes of which they are typical. A bathing solution containing erythrosine, for example, in conjunction with Columbia black gives a spectrograph which is vigorous in density as far as D 4 E, and then tapers down very abruptly to the insignificant red sensitiveness the black dye alone confers; it does, however, render the image more brilliant.

A plate bathed with a dye of this type requires specially adapted filters; the blue-violet filter must be darker than can be employed with other panchromatic plates; the green requires to be very luminous in the greenish-yellow region; the red filter must permit much the same light to pass as usual, but I have found a filter which works satisfactorily with all commercial makes will record some bluish-green rays, owing to the great proportional bluish-green sensitiveness.

A perfect panchromatic plate, when three successive exposures are made on it through the blue, green, and red filters, should reproduce the spectrum as an absolutely even band. With the standard filters used for these experiments, most commercial makes gave this result readily, but a plate dyed with colours of the above type entirely failed.

An interesting dye to colour workers is chlorophyll, unless properly isolated it varies very greatly in its sensitising properties. A solution is easily made by raising to boiling point a little alcohol in which some blades of grass are placed. This method saves the preliminary ether treatment, though it probably gives a very impure and inconstant solution. It behaves to some extent in accordance with the suggested theory but is of little value except in conjunction with collodion emulsion.

It might be mentioned that most of the above "data" confirmed by experiments with collodion emulsion. When variations have been experienced has been in the application of silver nitrate. Thus the addition of silver nitrate solution to Pluto black intensifies the red sensitising action, though it does not appear to materially influence Wool black; this can perhaps be accounted for by different chemical constitution.

A continued study of these and other dyes, which is, of course, carried out by spectroscopic means and camera exposures through the filters, may lead to some more definite conclusions, which I shall hope to communicate to the British Journal in due course. Meantime, every additional experiment points to the superiority of dyes of the cyanine type, the derivation of which can certainly claim precedence so far.

T THORNE BAKER, F.C.S.

THE QUESTION OF ART IN PHOTOGRAPHY.

[Translated from the "Photogramme".]

THE question of art in photography is not a new one. It dates back almost to the time of its discovery, but now it is recognised that photography is artistic, or at least capable of being so.

The reason of my returning to this question is that various articles published in important reviews are again bringing it to the front. It is the topic of the day, and as I always endeavour to keep the readers of this magazine in touch with what is taking place, I would like to say a few words about it.

First of all I must refer to an article by our distinguished confrère M. L. Gastine, which is the beginning of a study of art and professional photography. M. Gastine acknowledges with much truth the influence the exhibitions by amateurs have had upon the change which has taken place in professional photography, and he owns "that notwithstanding the great importance of the art movement in photography," there are still so few professional artists, that they could be easily counted on the fingers of one hand. They are not, however, altogether responsible for this want of progress. They have not the time to spend on a single work like the amateur, and they also have to take their customers into account. But let us leave the professionals alone, many of whom have yet to travel far on the road to art, and let us without ceremony turn to the great fight of which our review gives us the echo.

The cause this time is an article by Dr. Reiss,* published in the January number of the "Revue Suisse de Photographie," which, on account of the high reputation of the author is of vital importance. He says, in running through recent publications, and on visiting the exhibitions we have been stupefied by what one has actually dared to submit to the public. Although the attack is rather rough (our readers may form their own opinion of it, if they read the entire article), it contains much that is true. We have all seen, especially amongst the contributions of certain English and American exhibitors, pictures in which fuzziness oversteps the limits of the permissible and the vagueness of the drawing is such, that it is difficult to trace it in the grey indistinctness of fog.

According to Dr. Reiss the great evil is the abuse of the bichromate, which, nevertheless, "in the hands of a clever, conscientious worker may be very serviceable." We will return to this subject presently. But there is a closing criticism in

* See "BRITISH JOURNAL OF PHOTOGRAPHY" July 8, 1904, p. 600.

ard to which we are not in complete agreement with our eminent Swiss friend—it is concerning the selection of juries for our artistic exhibitions, or rather their composition. Dr. Reiss would like once more to see the majority composed of photographers—he might even permit the inclusion of a few painters and sculptors.

Our artistic exhibitions have quite a special character. M. Castigne's article shows what influence they have had and the progress they have brought about. It is not too venturesome to affirm that this fine result is largely due to the enlightenment of these juries, so happily brought into being by the Paris Photo-Club, and which the provincial societies have also found it worth while to adopt.

The reproaches which have been flung at gum bichromate have been met by a most competent opponent, M. René Le Begue. We find, in an article in "Home" of March 15, the situation described thus by our eminent colleague:—"From the day photography was divided into documentary and artistic—a division which is now admitted by all—two different paths have been clearly defined. Documentary photography renders such invaluable services that it would be puerile to discuss its indispensability and the immense interest attached to every branch of this new discovery. But as soon as we direct our attention to some other end than the document; as soon as we use technique only as a means; as soon as our ideal and our dream are not the production of an image fastidiously correct, scrupulously true to nature, but possessed of charm and beauty impressing itself upon the imagination; what does it matter about the purity of the negative and the perfection of the lens, the complete, scrupulous exactitude, so admirable, so precious in a document, but often so objectionable in art?" M. Le Begue continues by indicating the end the artistic photographer has in view and the means he employs. He answers the criticisms of Dr. Reiss concerning gum bichromate, and after pointing out its merits concludes very justly in the following terms:—"These qualities, which are so precious to the man of taste and the artist, become a stumbling-block to the expert operator. But it is not the process that should be criticised, but those who do not know how to use it." Our distinguished colleague could not speak with greater truth, and it seems to me that he has answered the criticisms of his learned opponent triumphantly.

Like all enlightened people M. Le Begue does justice to the photographic document and praises its value in highest terms. In this case the purity of the image cannot be dispensed with. It would be puerile to deny it. But if photography wishes to proceed, along the road to art, its freedom of action must be complete. If fuzziness, more or less pronounced, is necessary to produce the impression he desires, his work should not be rejected on that account.

The truth will always be found in those words of M. Le Begue which we have quoted above:—"It is not the process that should be criticised, but those who do not know how to use it." If fuzziness gives artistic qualities to a picture, it does not follow that fuzziness is artistic. If such works are shown at exhibitions (and we agree with Dr. Reiss that such unfortunately exist), we have the right to criticise them severely.

Artistic exhibitions have had a great influence upon photographic art, and even upon professionals, as we have seen. They should not be turned from the path, so happily traced for them, and sacrificed for regrettable snobbism. The eminent artists who form the juries at the present day extend to us their entire confidence, and their enlightened taste will certainly save us from such a fall.

A. LIEGARD.

The Kodak Competition Pictures are on view at the Kodak Gallery, 10, Strand, until December 17. Admission free.

CONTINUITY OF THE PHENOMENA OF SOLARISATION OF GELATINO-BROMIDE PLATES.

[Translated from the "Photographische Correspondenz."]

If a gelatino-bromide plate receives prolonged exposure, the well-known phenomena of solarisation make their appearance, since the normally exposed negative image, which has been developed, is covered by the solarisation image,¹ which gives a positive image on development. These phenomena until recently were looked upon as a process which acted continuously, but when Dr. Englisch published his studies entitled "The Periodicity of Solarisation,"² the use of magnesium light, with progressive exposures, disclosed the fact that there were light and dark intervals in the image, which appeared to give the solarisation phenomena a periodic character. For this reason I have investigated the question if it is a rule that solarisation is continuous or discontinuous in its nature, as it is of importance to the theory of photochemical processes with gelatino-bromide plates. In arranging my experiments I adhered to the working method adopted by Englisch, only, instead of magnesium light, I used an incandescent burner,³ because magnesium is not a sufficiently constant source of light, and also because it is questionable if the same amount of light is always emitted for a given unit of time. The incandescent gas burner was tested⁴ for its intensity with a Scheiner sensitometer by means of gelatino-bromide plates, and it was found to be 159 Hefner candles. I used various kinds of gelatino-bromide plates⁵ to obtain the phenomena of solarisation. They were exposed at one metre from the source of light by drawing successively the shutter of the dark slide at periods ranging from two seconds to one hour thirty-nine minutes, thus producing exposures ranging from 318 to 944,450 C.M.S.

The plates used were Schleussner's, Schatter's, Westendorp-Wehner's, and Lomberg's. The developers: ferrous oxalate, pyro-soda, metol-soda, and the time of development ranged from thirty seconds to five minutes.

In all these experiments, without any exception, the phenomena of solarisation were continuously progressive.

The addition of 10 per cent. of bromide of potassium to the pyro-soda developer,⁶ and 10 per cent. of ammonium bromide to the ferrous oxalate, set back considerably the appearance of solarisation, which agrees with the results given by Dr. J. M. Eder.⁷

Treatment of the solarised plate with chromic acid⁸ destroyed the solarised image to a degree representing an exposure of 255,000 C.M.S., and a normally exposed negative was obtained.

In all these reactions the phenomena of solarisation were continuous. In none of the experimental plates, which numbered about 100, could I detect the occurrence of any "periodicity of solarisation," which Englisch observed with intermittent magnesium light. Periodicity also appears to occur in exceptional cases only when using magnesium light, as I could not discover it when I rigidly complied with the conditions of experiment laid down by Dr. Englisch (repeated exposures of the gelatino-bromide plate with small pieces of magnesium ribbon burnt in succession).

In any case, my experiments prove that gelatino-bromide of silver solarises continuously, with great regularity, when exposed to the continuous action of light.

Vienna.

⁸ 1 gramme of bichromate of potash, 3 grammes of sulphuric acid and 100 c.c. of water.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

TRADE EXHIBITS.

In our previous notices of this Exhibition now open at the New Gallery, Regent Street, we have dealt only with the Competitive and Invitation Pictorial Sections. Turning now to the exhibits in the Trade Section, tastefully displayed in the Fountain Court, we find most of the leading manufacturers of apparatus and material represented. One or two well-known makers have elected to be represented only in the North Room—in the section more particularly devoted to professional photography. We will deal with these firms when reviewing this section.

In the Fountain Court, at the now familiar stall of Messrs. WELLINGTON AND WARD a series of big enlargements on "Wellington" platino-matt bromide paper from negatives on "Wellington" anti-curling celluloid films are again on view. The majority of these negatives are shown with others in an illuminated stand, and may be compared with the enlarged prints referred to. This enterprising firm, whose factories at Elstree are increasing in number with surprising regularity and rapidly, have also on exhibition tastefully mounted prints on rough, smooth, extra rough, and toned bromide papers, "enammo" glossy, thick and thin, S.C.P. glossy and matt, including their latest production, porcelain gaslight paper, which is an absolutely white paper with egg-shell finish, giving absolutely pure blacks with a full range of gradations.

MESSRS. J. H. DALLMEYER, LTD., show a small selection of their high-class cameras and lenses for all purposes, including the Adon telephoto lens, with comparative examples of its work with that of an ordinary lens. The stigmatic lens, series 2, continues a favourite with the public, and a new descriptive pamphlet setting forth its characteristics has been prepared. "The Service" prismatic binoculars, which have attained a great popularity, may be seen, and visitors may test for themselves the firm's camera back and shutter for facilitating studio work. The shutter is of the double flap variety, actuated pneumatically. The operator focusses the carriage, pushes the dark slide into position, the shutter being automatically withdrawn, and presses the bulb. The device is simplicity itself and should save much valuable time.

There is much to interest the visitor on Messrs. SANGER SHEPHERD AND CO.'S stall in the shape of apparatus and material for orthochromatic and natural colour photography. An item that will at once attract attention is a new one-exposure camera for colour photography. The three negatives are taken simultaneously on one plate by one lens. The camera is compact, especially when one considers what it has to contain; and the arrangements for splitting up the light rays into their three primary components are little likely to become disordered. The adjustment for the varying degrees of sensitiveness pertaining to different batches of plates is accomplished by a novel form of diaphragm so devised that the setting of the camera to ratio is merely a question of adjustment of diaphragm, a compensating screen being unnecessary. Two or three finished transparency pictures taken with this camera may be seen on the stall, and very good they are. The camera is made in three sizes. The smallest takes a $6\frac{1}{2} \times 2\frac{3}{4}$ in. plate (half of a $\frac{1}{2}$ -plate); the second, $8 \times 3\frac{1}{4}$ in.; and the third, a stereoscopic pattern, takes a plate 8×5 in. The Chapman-Jones sensitometer is on view, and it may be pointed out that this is now supplemented by a new instrument for ascertaining the relative red, green, and blue sensitiveness of colour sensitive plates. The device consists of a graduated plate, $4\frac{1}{2} \times 3\frac{1}{4}$ in., covered by three strips of coloured filtering medium, each furnished with a numbered scale. The relative sensitiveness to the several colours is at once obtained by exposing a plate to daylight behind this screen, developing, and consulting the facts thus recorded. The well-known spectroscopic camera of this firm is now made in a cheaper form, with slight modifications, one of which is the enclosing of the train of prisms to protect it from injury. New models of apparatus for speed determination, after Hurter and Driffield's method, may be seen as well as one of a half-plate camera for survey work. Another exhibit that will attract attention and be useful in photographic work in many ways is the small automatic arc lamp, giving a light equal to about 125 c.p., with a consumption of $1\frac{1}{2}$ amps. on a 100 volt direct current circuit. The consumption is so small that the lamps may be safely attached to the ordinary installation for incandescent lamps. We were also shown a pneumatic shutter and repeating back for use in colour photography,

devised to facilitate the successive exposures of the three plates. With this it is possible to take an open landscape on the three plates or after another in as little time as three seconds.

For direct portrait work in colour and many aspects of medical work to which three-colour photography is extensively applied, such a means of rapidly exposing and changing the three plates is very necessary.

There are some excellent lantern slides in colour made by the firm's method, and a very fine large portrait on paper by the same method. The colours are delicate and free from any crudeness. We understand that a special camera for portrait work will probably be on the market very soon.

We were shown one or two interesting examples of the employment of three-colour photography in medical work. Several of the hospitals make use of the process, a stereoscopic camera having been employed for recording the colour of the affected parts and the form of the eruption in skin diseases. Bacteriologists likewise find colour photography by this method invaluable in their researches, and many of the Universities and teaching bodies now use colour slides in place of the older, slower, and less satisfactorily methods of class demonstration.

Finally, we must draw attention to the frame of accurate colour filters or screens, which are now supplied for any brand of plate on the market.

The enterprising house of HOUGHTONS, LTD., has put up an attractive stall for the display of an interesting collection of cameras and accessories. The following models of the popular "Sanderson" hand camera may be seen—Regular, Tourist, Junior, Roll Film, and Deluxe—and the "A," popular, and Junior popular types of the "Sanderson" field camera are also on view. The "Holborn" and "Klito" hand cameras also find a place, and we must not omit to mention the "Ensign" roll films, for the "Ensign" and all roll film cameras. The firm is also demonstrating the "Standa" tank for the stand development in daylight of glass plates and flat films. The tank consists of an upright metal vessel and a removable inner chamber grooved for twelve plates. The developing solution is poured into the outer vessel up to an indicated level, and the inner chamber containing the plates, securely capped, is slowly introduced. The developer enters the inner case through a light-tight aperture at the bottom, provision being made for the escape of air at the top. The tank is made in $\frac{1}{4}$, 5×4 , and $\frac{1}{2}$ -plate sizes. The "Dalo" developing chamber for one plate can also be seen. The firm show numerous other pieces of apparatus, amongst which may be mentioned a compact daylight enlarger with which from $\frac{1}{4}$ to $\frac{1}{2}$ plates can be enlarged to any size not exceeding 15×12 in. The apparatus can be employed without difficulty as a 15×12 camera. With the approach of the winter, their lantern list, which describes much that is interesting to the lanternist, may be perused with profit.

C. P. GOERZ, of 1 to 6, Holborn Circus, E.C., has again the centre stall this year. Various articles of the firm's manufacture will be found here. Their new model focal plane shutter is now made to give short exposures of $\frac{1}{2}$, $\frac{3}{4}$, 1, 2, 3, 4, and 5 seconds as well as prolonged time, bulb and snapshot exposures. On giving the setting screw a half turn—against four or five in the older form—instead of the adjustable slit appearing, the whole aperture is exposed; this, with another slight turn, is ready for use with the bulb for the short time exposures which are regulated by means of an air escape. A further half turn winds up the slit, and the shutter is then ready for the ordinary flash work. To again obtain the full aperture it is only necessary to press the trigger on the right-hand side of the shutter, holding down in the meantime the small metal knob on the top left-hand side.

MESSRS. W. WATSON AND SONS, of 313, High Holborn, W.C., show several forms of the "Antinous" release for shutters, replacing the rubber ball and tube. The latest form is provided at the end with a loop to engage with the trigger of shutters of the Bausch and Lomb type. An instrument we were rather pleased with is the new model "Vril" for half-plate and stereoscopic work. This camera is of the familiar Goerz-Anschütz form, being held out at the full extension by means of springs. The front panel takes the two lenses, the centre being adjustable from $2\frac{1}{2}$ to $3\frac{1}{4}$ inches, and in this form is used for stereo work. For half plates the panel holding the two lenses is removed, and in its place is put what is really a second similar camera thus obtaining the necessary extra extension. The focal plane

utter (Messrs. Watson's own pattern) serves for both forms. The well-known "Acme" camera by the same makers has been brought to date by the addition of triple extension and an extreme rise of front. On this stand will also be found the "Argus," a reflex camera with focal plane shutter. The machine is small, of light weight, and fitted with front extension by rack and pinion. Several of the firm's stigmat lenses are exhibited, as also are examples of work done therewith. The two combinations are corrected for use singly as long as lenses.

The Watson-Conrady system for photomicrography, which is also known, consists of (1) the condenser, fitted with an Iris diaphragm; (2) a glass tank—easily taken apart for cleaning—to contain heat-absorbing or coloured media; (3) an Iris diaphragm, with or without an auxiliary concentrating lens; (4) the illuminant. A very neat and effective stereoscopic camera in the shape of a book is also worthy attention.

The ROTARY PHOTOGRAPHIC CO., LTD., have a tastefully enclosed case in which are shown prints upon Rotograph bromide paper, matt and glossy, in seven grades; Rotox gaslight paper, matt and glossy, in three grades; Rotary carbon tissue in twenty colours; Rotograph bromide and Rotox gaslight postcards in three sizes; Roto roll film; and, finally, specimens of their three-colour pigment stripping film for colour photography. On the outer wall of the stall will be found a smaller print, though still of good proportions, of the large photograph of the Bay of Naples, which was sent to the St. Louis Exhibition.

The small stall of Messrs. SANDERS AND CROWHURST, who this year have opened a branch at Hove, contains much that is worthy of examination, including the Birdland camera, a focal plane reflex of triple extension, in its latest form, with reversing frame, and the very small and serviceable "Bloknote" camera. The Southport enlarging stand, 15 x 12 may be seen, and it may interest our readers to know that this is now made in special form to suit the purchaser's particular requirements.

Messrs. BURROUGHS, WELLCOME, AND CO., of Snow Hill Buildings, London, C., have a very tastefully decorated stand, and show a number of the well-known "Tabloid" brand compressed chemicals for use in all branches of photography. Let into the two towers flanking the stand are a number of lantern slides, some of them being toned to various colours by means of copper ferrocyanide and other reagents in "Tabloid" form.

The PLATINOTYPE Co. occupy their usual position. They show a number of American photographs, the major part being on the company's sepia paper. Various examples on the different grades of paper are on view, and frequent demonstrations of the development of the papers are given. The firm also exhibit their tissue storage box for carbon and platinum. This is in form of a metal cylinder cased in wood, provided at the bottom with a tray with perforated top for holding the calcium. The top of the cylinder has a domed copper top with a thick band of rubber round the edge, and when the lid is in position the knob is pressed, forcing out the rubber and thus ensuring an airtight joint. The Platinotype Portrait Lamp is also to be seen.

KODAK, LTD., who reoccupy the space for some years associated with their name, have a very comprehensive display. There is a complete range of Kodak and Premo cameras, whose features are too well known to call for detailed description. The daylight developing machine may be seen in use and specimen prints on the firm's papers, negatives on kodoid and seed plates and roll film will be found. The latest model of the Brownie is also exhibited.

Altogether we are glad to note that this section maintains its popularity and interest. The firms who are represented are to be congratulated on a very attractive display.

Mr. R. R. BEARD, the well-known lantern expert, of 10, Trafalgar Road, Peckham, London, S.E., sends us his latest catalogue of scientific instruments, optical lanterns, cinematographs, oxy-hydrogen jets, governors, and carriers, and general apparatus. It is a freely-illustrated publication, of about fifty pages, which should be in the hands of all those interested in optical projection work, on which subject Mr. Beard is one of our highest practical authorities, whose advice and experience may quite be relied upon by both the expert and the novice.

THE MANIPULATION OF PLATINUM PAPER.

In an article which appeared in these pages recently, the successful treatment and working of old platinum paper and the saving of over and under-exposed platinum prints was so thoroughly treated that nothing further in that direction seems requisite. It is my purpose in the present paper to set forth the possibilities of the platinum process, treating the subject from a different standpoint. Upon the regular or "black" papers, colours may be obtained ranging from a very cold to a very warm black. A most beautiful red or green may be secured by simply toning the print; a sepia colour can be obtained by the introduction of bichloride of mercury into the developer. Moreover, prints of a greater or less contrast may be made from the same negative by altering the developer, by manipulation in printing, and by other means. It is to this side of platinum printing that I shall give my attention, writes Mr. W. E. DASSONVILLE in an American contemporary.

When it is desired to give to the print that sense of warmth felt in late afternoon and twilight landscapes the sepia colour obtained by the hot developer or the use of mercury is best suited. These varying shades of sepia will also be found pleasing for many portraits. The red colour is particularly adapted to sketchy effects both in portraiture and in landscapes, suggesting as it does red crayon. The green is not so suitable for landscapes as might be supposed but for marines it probably answers better than any other colour.

These formulæ have stood the test of my every-day practice for several years. They have in my hands been found the simplest and most suitable of a great number of published formulæ which I have given careful trial. Since it is impossible without illustrations to show the exact colours and gradations obtained it would be advisable for the worker wishing to fully avail himself of the processes outlined, to make up a set of prints, showing the different results obtainable from the same negative. Such a set of prints will permit him to make an intelligent selection of the process most desirable in any given case.

RED OR GREEN PRINTS.

To make a red platinotype, proceed as follows, making up three solutions:

No. 1.	Uranium nitrate	48 grs.
	Glacial acetic acid	48 min.
	Water	1 oz.
No. 2.	Potassium ferricyanide	48 grs.
	Water	1 oz.
No. 3.	Ammonium sulphocyanide	½ oz.
	Water	1 oz.

When ready to use take one part of each solution and add 100 parts of water. In this final solution place a finished print; one developed, cleared, and washed. It will immediately commence to tone to a colour termed Bartolozzi red; the longer the print is immersed the darker the colour will become. When the desired depth of colour has been obtained remove the print, washing it in several changes of water made slightly acid by acetic acid, and then dry.

These acid baths are important since the slightest trace of alkalinity will entirely remove all of the red colour, leaving the print as it was before being toned. It may be seen by this that should the print be toned too dark it can be cleared of its colour by being rinsed in water to which has been added a small amount of any alkali. After this the print may be well washed and again toned to the colour desired. When mounting prints which have been toned with nitrate of uranium it is advisable to add a few drops of acetic acid to the paste used.

To produce a green platinotype, tone the print red as just describe 1; rinse in an acid bath and then immerse for a few minutes in a bath of bichloride of mercury; 18 grains to the ounce of water. From this bath the print is transferred, without washing, to a solution of trichloride of iron, 10 grains to the ounce of water. In a few minutes the desired colour is obtained. The print is then well washed in several acid baths and dried. It is generally supposed that prints treated in this manner are not permanent, but some prints made about four years ago show no signs of deteriorating.

INTENSIFYING PLATINUM PRINTS.

It often happens that prints when finished are too weak, and, ordinarily, are thrown away. Such prints are easily saved by intensification. Make a solution of:

Hydroquinone	2 grs.
Citric acid	60 grs.
Water	3 ozs.

When the chemicals are entirely dissolved add 10 grains of nitrate of silver. The platinum print is placed in this solution and allowed to remain until sufficiently intensified, when it is removed, given a slight washing, and fixed in a weak solution of hypo, after which it is well washed and dried.

SEPIA PRINTS BY THE USE OF MERCURY.

The introduction of bichloride of mercury into the developer changes the resultant colour from a black to a sort of sepia. The amount of mercury required depends upon the effect desired and also upon the paper which is used. As a general rule, with the American platinum, from one-quarter to one-tenth of a grain to the ounce of developer will be sufficient. With the Willis and Clements' paper, from one to one and a-quarter grains to the ounce will usually be found necessary. Using greater quantities than these produces a rather disagreeable colour, and it will also be found that the greater the amount of mercury used the less the half-tones are preserved. Prints treated in this manner have one great drawback; they are permanent only when the iron contained in the paper is entirely removed by the acid baths, but washing the prints in these baths has a very strong tendency to remove all traces of the sepia colour, owing to the action of the hydrochloric acid upon the mercury. A print developed in a mercury developer will have lost all its colour by the time the iron is entirely removed if an average strength of acid clearing bath be used.

The only way which I have found to overcome this difficulty is to leave the prints in the developer for at least four minutes, thus giving the mercury plenty of time in which to act, and then clear the prints in three weak acid baths of: Muriatic acid, 1 ounce; water, 200 ounces. By following this course the loss of colour will be very slight and the iron will be entirely eliminated.

EXTREME CONTRASTS, COLD AND WARM BLACKS.

It often happens that for some reason a print very strong in contrast and cold in colour is desired. To secure this, the following developer answers admirably:

Neutral oxalate of potash	16 ozs.
Phosphate of potash	4 ozs.
Sulphate of potash	$\frac{1}{2}$ oz.
Water	100 ozs.

The solution should be used cold and the print immersed as usual. The length of time required to develop is at least five minutes, the image appearing and developing very slowly. After development the prints should be rinsed in the three customary acid baths of: Muriatic acid, 1 ounce; water 50 ounces. In mixing up formulae containing neutral oxalate of potash, the oxalate should be first entirely dissolved and the solution then tested with litmus paper. Should it prove acid, neutralise with carbonate of potash; if alkaline, slowly add oxalic acid until neutral.

Another method of securing greater contrast without at the same time producing cold blacks is to place a piece of blue glass over the negative while printing. As it is difficult to procure such glass entirely free from spear points and bubbles it is advisable to paste over one side of the glass a piece of French tissue-paper. With the papered side toward the negative place the glass over the printing frame, never in contact with the negative. By this means the shadows from the bubbles are prevented, and the print will show no mark from them. Using the developers which are supplied by the various manufacturers of platinum paper one generally obtains a medium gray print when they are used at a normal temperature, say 70 degrees Fahrenheit. By heating the developer, even to the boiling point, the colour becomes warmer, varying according to the temperature of the solution. The increased temperature of the developer plays another important part by materially reducing the contrast of the print. By holding the print over the steaming solution before developing, and until the surface has had an opportunity of becoming slightly moist, a still further decrease in contrast will result. Another method of producing a print with lessened contrast is to remove the paper from the tin the evening before printing and allow it to remain over-night, without the package of preservative, in a closed drawer. The paper will become slightly dampened and give, when used judiciously, beautiful soft effects without the warm black colour produced by the use of a hot developer.

SPOTS ON C.C. PRINTS.

Of the more frequently recurring questions of the many ever pressed ones asked and answered in the correspondence columns of this Journal that regarding the cause of yellow spots on C.C. prints appears to be among the more pressing. As—judging from the answers given—it appears to be some slight haziness on this subject, I hope the following note may be of use, especially as I wish to draw attention to one or two usually unsuspected causes of what has been not inaptly termed "the yellow peril." Yellow spots may appear at any time during and after the manipulation of the prints, but usually are noticed after the prints have been mounted and dried, either at once or at varying intervals, according to the particular cause of the evil.

It is noteworthy that prints toned in the gold bath alone seldom show the blemishes, these latter nearly always appearing on prints toned in both gold and platinum. As this is the process usually worked by the professional, let it be understood that the double bath method is particularly referred to in the following. Washing gold toning and platinum toning are in themselves not liable to lead to trouble if pure chemicals are used; the first likely cause is the necessity of washing after toning in platinum. This washing must be thorough, acid from the platinum bath will be carried into the hypo, causing sulphur toning, and in course of time yellow spots. Washing prints to discharge the acid must be done by hand, as running water is quite useless. Six changes in fifteen minutes will be right for a medium batch, but increase this if prints number more than about a hundred cabinets. To make absolutely certain that prints shall be neutralised in fourth washing water, put a few drops of carbonate of soda solution. Then give three farther changes in clear water, also placing a little of the alkali in the hypo.

Insufficient fixing is another frequent invitation to the enemy. The makers of many papers recommend for the bath: Hypo, 1 ounce; water, 20 ounces. I have always thought this ridiculously inadequate, and always use, not only without detriment, but probably with great gain, hypo, 3 ounces; water, 20 ounces, for from fifteen to twenty minutes.

The best way to wash these prints is to give several hand washes immediately after fixing, then wash in running water for two or three hours, and again hand wash. Say, running water two hours, hand washing twenty minutes. Hand washing is best done by transferring prints from one bowl into another containing clean water. If prints are to be dried for cutting out, blot between pure paper and then spread on clean sheet or fresh blotter.

Mounting should be done with pure starch, made same day, certainly not more than twenty-four hours old. The reader will probably think that the prints, having got so far, are now quite safe. Such is not the case, for one of the most insinuating, and, in England, at least, the most unsuspected dangers is yet to come.

After mounting the prints must be dried as quickly as possible, and not placed on top of one another until quite dry. Why slow drying should cause spots I am quite unable to understand, but such is undoubtedly the case, not only from bitter experience, but also from the experience of others. Moreover it will be noted that I say unsuspected in England, but in America the fact is well known, the Aristotype Company laying great stress on this point. They recommend that each print be put through very hot rollers, with card over face. This is doubtless a safeguard, but I think that if the danger is recognised very few precautions will guard against it. The precaution of drying prints in rooms with fire during damp weather will, of course, be obvious, and at the same time do not place too near fire or dust therefrom is likely to be another cause of the everlasting yellow spot. It will doubtless have been noticed by some at least of my readers that these complaints of yellow spots on C.C. are more frequent at damp periods of the year. How important the above is to all members of the profession can only be judged by the professionals themselves, for blemishes of the startling description of the yellow spot cannot but in the long run ruin, not only the work and reputation, but the photographer also. The C.C. process is, however, very beautiful, and, we think, well worth the extra

able to guard against faults, for a well made print is well nigh permanent when once made. To ensure perfect results, do not forget that requires the greatest attention and personal supervision at each stage. Also do not do too large batches; you will find it quickest to make two batches of one hundred and fifty cabinets than one batch of two hundred and fifty at a time.

W. FOSTER BRIGHAM.

THE "BRITISH JOURNAL OF PHOTOGRAPHY" IN AUSTRALIA AND NEW ZEALAND.

THE August number of the "Australian Photographic Journal," published in Sydney, contains the following: "So far back as the year 1864, Lord Salisbury (then Lord Robert Cecil), in a lengthy article upon photography, wrote; 'Of all the marvellous discoveries which have marked the last hundred years, photography is entitled in many respects to take its rank among the most remarkable.' The Marquis did not venture a prediction of what might happen in the future. The BRITISH JOURNAL OF PHOTOGRAPHY, under the title of the 'Liverpool Photographic Journal,' had come into existence just ten years before the above quotation was penned, and in the present year is celebrating its jubilee. Sitting back in our chair, here in far away Australia, to permit ourselves for the moment to wonder what the Right Hon. Marquis would say could he join in the Journal's celebration and review its fifty years' records of facts? We may safely suggest that, with us, he would voice the opinion—'a faithful report of splendid achievements!' It is impossible for us to find space to satisfactorily hint at the work done by the 'B.J.P.' in its life of fifty years, as to the diamond lines of some old tome, the remembrances, the recollections, the reminiscences of men who have been actively engaged in photography, and contributors to the B.J. columns, for the whole of the fifty years. Mr. H. N. King, one of the oldest and most experienced professional photographers, and Mr. G. Watnough Webster, F.R.C., F.C.S., and others write from this standpoint, while to name the interesting and instructive article on special subjects, such as 'The Present Position of Pictorial Photography,' by Dr. P. H. Emerson; 'Half a Century of Camera Evolution,' by E. J. Wall; 'Handling the Adult Sitter,' by H. Snowden Ward, F.R.P.S., would mean practically to name them all. In a word, the number is excellent, and the Editor may be proud that he is entirely justified in holding it forward for criticism, not only on its own merits, but on the contingent merits of the past weekly issues. The 'B.J.P.' holds an unique position. Of the weekly journals it is the hub. From it ray forth to photographers the lights which guide them, and in it may be found the records of scientific photography, of professional photography, of amateur photography, and of all pertaining thereto. Advice and news from its columns are to be relied upon for correctness, and they are thoroughly up to the hour. Our dependence upon it we readily and with pleasure admit, for at this distance from the world's headquarters the 'B.J.P.' tells us in the quickest possible time exactly what is going on. It may well be proud of its past."

"Sharland's New Zealand Photographer" says:—"The Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY has just come to hand. It is a very bulky number, of about a hundred pages, issued at the usual rate—the modest twopence. It contains a history of photography during the half-century, and a series of most interesting papers on subjects which to-day are engaging the attention of experts in their various departments, illustrated with portraits of the leaders in the literature, art, science, and technique of photography. A list of the contents would nearly fill one of our columns, and the Editor has secured the assistance of many names well known to readers of photographic journals, so that this Jubilee Number presents a rich treat to all its readers. We wish the publishers had sent us a few hundred copies; they would have been very quickly disposed of. Such value was certainly never previously offered."

Exhibitions.

NEWBURY.

THE members of the Newbury Guildhall Camera Club are to be congratulated upon the success, from an artistic point of view, which attended their second exhibition of pictures, the product of the camera and its devotees, both professional and amateur. Encouraged by the success achieved on a former occasion with a modest project, the Club this year were much more ambitious in their aims, and the collection of some 1,300 or 1,400 pictures that were on view in the Town Hall, which for the nonce was turned into a photographic salon, was undoubtedly the best that has been seen in Berkshire and the adjoining counties, and would prove a strong rival to some of the more famous collections in some of the big cities and towns of the country. The hall itself would not accommodate the whole of the exhibits, and the gallery and staircase had to be requisitioned for the purpose. Not only were the number and quality of the photographs shown of a large and high character, but the manner in which they were displayed and the whole arrangement of the exhibition reflect the greatest credit on the members of the Club who formed the various committees who were responsible for the same. The Club has as its president the Rev. J. M. Bacon, M.A., F.R.A.S., while Miss Gertrude Bacon, his daughter, who is scarcely less famous, is the president of the exhibition.

The exhibition was formally opened on Tuesday in last week by Lady Wantage in the presence of a distinguished company.

Space will not permit of our describing the exhibits singly, and we cannot do more than give a list of the prize winners. The judges were:—Harold Baker, A. Horsley Hinton, Reginald Craigie.

Portraiture and figure study (open to amateurs or professionals).—First prize, £5 5s., A. M. Walters, Forthampton Vicarage, Tewkesbury, "A Dutch Cap"; second, £2 2s., Andrew Paterson, 15, Academy Street, Inverness, N.B., "The plotter"; highly commended, Miss Agnes B. Warburg, 8, Porchester Terrace, London, W., "The Noah's Ark."

Architecture, exterior or interior (amateur or professional).—First, £3 3s., Rev. H. R. Campion, West Fen Road, Ely, "Quomodo dilexi"; second, £1 1s., S. G. Kimber, Southampton, "From transept to nave, Winchester."

Landscape, river scenery and marine (amateur or professional).—First, £4 4s., A. Marshall, Nottingham, "Shadows"; second, £1 11s. 6d., D. Murray, Wolverhampton, "On Cannock Chase"; highly commended, F. J. Phillips, Brighton, "A sandy track."

Instantaneous, showing evidence of motion (amateur or professional).—First, £3 3s., A. S. Orlebar, Tetworth Hall, Sandy, Beds., "Start of the Redwings"; second, £1 1s., G. Cleland, Edinburgh, "Lowest"; highly commended, B. H. Bentley, M.A., F.L.S., University College, Sheffield, "Queen of the Air."

Flowers, fruit, still life, or any subject not otherwise classified (amateur or professional).—First, £3 3s., E. Seymour, Watford, "Flower Study"; second, £1 1s., Miss M. C. Eames, Wedford-on-Avon, Stratford-on-Avon, "Poppies"; highly commended, A. W. Walburn, West Hartlepool, "Ivy Geranium."

Local portraiture and figure studies.—First, £2 2s., Miss C. E. Power, Watership, Newbury, "Portrait of Robert Etheridge, Esq., F.R.S."; second, £1 1s., A. R. Pym Sutton, Bucklebury Place, Reading, "Dragoman, Syria"; third, 10s. 6d., Mrs. Yates Bainbrigge, Donnington Villas, Newbury, "Greek Figure."

Architecture (local).—First, £1 11s. 6d., A. R. Pye Sutton, "Milan Cathedral"; second, T. C. Beynor, "Cheriton," Newbury, "Five Arches, Tenby"; third, 10s. 6d., T. M. Morris, Newbury, "Old House, Strasburg."

Landscape, river scenery and marine (local).—First, £2 2s., C. Rupert Dolton, Newbury, "The Avenue, Highclere"; second, T. C. Beynor, Newbury, "Cheriton Church"; third, 10s. 6d., P. F. Davis, Craven Road, Newbury, "On the Lambourn."

Instantaneous photographs (local).—First, £1 1s., Rev. H. A. Sealey, The Vicarage, Hungerford, "Wave Study"; second, 7s. 6d., Miss C. J. Bacon, Earlstone, Newbury, "Off to Glasgow."

Flowers, fruit, still life, animals.—First, £1 1s., P. F. Davis, New-

bury, "In summer shade"; second, T. C. Beynon, Newbury, "Craven Hounds."

Novice class.—First, camera, value £4 4s. (presented by Miss G. Bacon), Mrs. A. S. Batson, Hop Benham, Newbury, "Views near Boxford"; second, £2 2s. (presented by Miss G. Bacon), Miss Osmond.

Old Newbury class, prizes given by the Mayor of Newbury.—First, £2 2s., T. M. Morris, Newbury, six views of historical Newbury (the same exhibitor was second prize, but was debarred); second, £1 1s., J. Steptoe, "Donnington Castle"; third, 10s. 6d., W. N. Whaley, Newbury, six views of Newbury.

Photographic postcards (amateur or professional).—First, £1 1s., W. H. Foxall, Trinstall, "Toilers of the harvest"; second, 10s. 6d., H. S. Talbot, Cold Ash, Newbury, "In the Jama, Musgid, Delhi, India"; third, 5s., F. B. Richardson, Scarborough, "Sleep."

Junior Class (local).—First, £1 1s., W. Freemantle, Northbrook Street, Newbury, three views of Ilfracombe Harbour, Capstone Rock, and Newbury Bridge; second, 10s. 6d., A. H. Davis, Northbrook Street, Newbury.

Lantern slides (any subject), sets of four.—First £3 3s., S. G. Kimber, Southampton; second, G. A. Booth, Preston; highly commended, G. Cleland, Edinburgh.

Lantern slides (any subject), sets of four (local).—First, £1 1s., J. Steptoe, Newbury; second, 10s. 6d., T. M. Morris; highly commended, Miss G. Bacon.

Stereoscopic (any subject), sets of four (open).—First, £2 2s., H. Wormleighton, Leicester (who was also second but debarred from taking the prize); second, £1 1s., H. E. Lewis, Colville Road, Essex; highly commended, A. W. Westropp, Bridgnorth.

There was a remarkably fine loan collection. Amongst the exhibitors were H.R.H. Princess Christian, H.H. Princess Louise Auguste, Lord Stanmore, Rev. J. M. Bacon, the Kodak Company, whose Russo-Japanese war pictures attracted general attention. Walton Adams, of Reading, had some attractive portrait studies. The Autotype Company exhibited a selection of their most attractive work. Victor White, of Reading, had a number of landscapes, Mr. G. W. Palmer sent views taken of his recent travels in Japan. A series of pictures were lent by the Royal Photographic Society and the Camera Club. Mr. Frank Thoyts' photos were those of the funeral of the late Queen. Mr. Righton showed interiors of many of the mansions in the neighbourhood and specimens of portraiture. Other work was sent by the Platinotype Company, the Langflier Company, J. H. Dallmeyer, Ltd., a series of children's studies by Messrs. Speaight. Sir Benjamin Stone had on view a selection of his famous Parliamentary and historical pictures. Miss Acland lent several of her examples of colour photography. Dr. E. S. Grün was showing the three-colour process and work done by the Grün liquid lens. Messrs. Hawker, Messrs. Wellington and Ward, Mr. Pym Sutton, Mr. W. Whaley, Messrs. W. and D. Downey, Mrs. G. A. Barton, Miss King, "Focus," Mr. E. H. Carpenter, Mrs. J. E. Nelson, Mr. C. F. W. Peirson, Mr. Horsley Hinton, and others also showed pictures, which helped to make up a splendid collection of loan exhibits.

Mr. Richard Kerr, F.G.S., F.R.A.S., was engaged to give a series of scientific expositions on Wireless Telegraphy, Tesla's High Voltage, Microscopic Wonders of Marine Life, Radium, the Harmonograph, the Gyroscope, Colour Photography, during the exhibition. Miss Gertrude Bacon lectured on "In odd corners with a camera." The Guildhall Dramatic Society gave performances of Jerome's comedy "Barbara," and Hurst's "True Colours." The musical arrangements were in the hands of Mr. A. H. Drury, A.R.C.O., and concerts of high-class music by leading local amateurs were given twice daily. Cinematograph displays were frequently given, also exhibitions of prize lantern slides. There were demonstrations of various photographic processes, and a cabinet of stereoscopic transparencies lent by Messrs. Lumière afforded much pleasure.

The committee are to be congratulated upon the artistic catalogue which they issued, containing some excellent reproductions of famous photographs.

FORTHCOMING EXHIBITIONS.

October 15-29.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Clappole, 112, Hawthorn Road, Kettering.

October 19-20.—Isle of Wight Photographic Society. Hon. Sec., J. Howard Burgess, 53, Pyle Street, Newport, I.W.

October 19-22.—Rotherham Photographic Society. Hon. Sec., C. Hemmingway, Tooker Road, Rotherham.

October 26-28.—Watford Camera Club. Hon. Sec., H. G. Telford, 3, The Parade, Watford.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretaries, L. C. B. Appleby, Barnbygate House, Newark.

November 2-23.—Plymouth. Hon. Sec. Photographic Society, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selve, 70, Paragon Road, Hackney, London, N.E.

November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Cox, 52, Frederick Street, Sunderland.

November 17-18.—Braintree and Bocking Camera Club. Hon. Sec. W. H. Tilston, 81, Iligh Street, Braintree, Essex.

November 17-19.—Darwen Photographic Association. Hon. Sec., J. G. Thomas.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmar Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexander Parade, Dennistoun, Glasgow.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-1 West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubery, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 12-14, 1905. Boston Camera Club. Hon. Sec., H. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseille. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Strath Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Sol, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve lectures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 or lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

THE SAME OLD STORY.

The following is taken from the Berlin correspondence of a recent issue of the "Daily Express":—

"The German scientist Dr. Koenig, of Hoechst, announced this afternoon to a congress of scientists assembled at Breslau that he had succeeded completely in solving the problem of coloured photography, which has hitherto baffled the most expert photographers. Dr. Koenig said he had discovered a perfectly simple process whereby every shade of colour in the photographed object was reproduced to perfection in the photograph. The process was so easy that any amateur would be able to carry it out with the same facility that he now takes snapshots. Further, it is only a fraction more expensive than ordinary photography. The process reveals whether a man wears a black or dark blue coat, whether a gold or silver watch-chain, whether he has ruddy or pale complexion, and other details to perfection. After the negative is taken the coloured photograph can be copied in forty seconds, and retains all the shades of colour in the copy. Dr. Koenig is to explain the technical details to the congress. Experts who have investigated his claims declare that the discovery is amazing."

Patent News.

The following applications for patents were made between September 12 and September 17, 1904:—

Plates and Films.—No. 19,940. "Improvements in and relating to photographic plates and films." (Date applied for under Patents Act, 1901, September 17, 1905, being date of application in Germany.) Complete specification. John Henry Smith.

The Scottish Salon.—The second annual Scottish National Salon of the Scottish National Federation, will be held in the galleries of the Royal Glasgow Institute of Fine Arts, 270, Sauchiehall Street, Glasgow, from January 14 to January 28, 1905. Entry forms and all further particulars may be obtained from the hon. secretary of the salon committee, Mr. W. A. Frome, 28, Bank Street, Hillhead, Glasgow. The prospectus states that the exhibition will be open to the works of all photographers (professional or amateur) resident in Scotland; also to the works of Scotsmen not resident in Scotland and that independent of their being associated to the Scottish Photographic Federation.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
8	Royal Photographic Society ...	{ Slides by Members of the North Middlesex Photographic Society.
10	Royal Photographic Society ...	{ A Popular Talk on Colour Photography. Mr. T. K. Grant.
10	South London Photo. Society...	{ Cameras and Apparatus. Mr. H. Creighton Beckett.
11	Architectural Asso. Cam. Club	{ Westminster Abbey. Messrs. S. B. Bolas, F.R.P.S., and D. M. Mackenzie.
11	Hackney Photographic Society	{ A Talk to Beginners about Improving the Negative. Rev. F. C. Lambert, M.A.
11	Birmingham Photo. Society.....	{ Annual Meeting.
11	Glasgow Southern Photo. Asso.	{ Hat Night.
12	G.E.R. Mechanics' Institution	{ Affiliation Lecture.
12	Boro. Poly. Photo. Society	{ Some Practical Hints. Mr. R. R. Rawkins.
12	Royal Photographic Society ...	{ Marine Photography. Mr. F. J. Henderson.
13	London and Prov. Photo. Asso.	{ Henderson Award Meeting.
13	Hull Photographic Society	{ Gas-Light Papers. Demonstrated. Mr. W. J. Williams.
14	Bowes Pk. and Dis. Ph. Soc. ...	{ R.P.S. Exhibition.
14	Boro. Poly. Photo. Society	{ Instruction Evening.
14	G.E.R. Mechanics' Institution	{ Visit to the R.P.S. Exhibition at the New Gallery, 121, Regent Street.
14	Wakefield Photo. Society	{ Retouching. Demonstrated. Mr. John Way.

MOTHERWELL YOUNG MEN'S INSTITUTE CAMERA CLUB.

The annual general meeting was held on Monday evening, September 19. The secretary, in reading his report, gave an excellent account of the club's work during the past year. At the last annual general meeting the membership roll was 38; during the year 19 new members have been enrolled, making a total of 57, thus showing that the club is in a flourishing condition. The treasurer, Mr. Dugald Taylor, presented his report and accounts for the past year, showing a very satisfactory balance on the right side. The election of office-bearers for session 1904-5 resulted as follows:—Hon. president, Alex. Findlay, Esq., M.P.; president, Mr. Robert Kilpatrick; vice-president, Mr. J. S. Taylor; treasurer, Mr. Dugald Taylor; secretary, Mr. James Dunlop; auditors, Mr. John Whillas and Mr. D. Martin; council, Mr. William Millar, Mr. Dan Dunlop, Mr. Arch Bishop, Mr. Alex. McDonald, Mr. Robert Frew. The council are at present busy arranging a fine syllabus of lectures and demonstrations for the winter evenings; non-members are invited to these meetings. The third annual photographic exhibition of the club takes place on November 3rd, 4th, and 5th next, and promises to eclipse any former exhibition held in the town. The secretary, Mr. James Dunlop, "Myrtle Bank," Wilson Street, will be pleased to forward full particulars to anyone interested, on receipt of post-card.

BELFAST Y.M.C.A. CAMERA CLUB.

The annual meeting of this club was held at Wellington Place on the evening of the 20th ult., the President, Mr. Moffett, occupying the chair. The secretary read the annual report and statement of the club's finances, showing a very satisfactory balance at credit. Both statements being adopted, the members next proceeded to elect the officers for the season. Mr. R. J. Moffett, who had filled the presidential chair during the past two years, was unanimously re-elected. The following were elected vice-presidents: William Downing, J. J. Macauley, A. K. Hogg, Richard Hamilton, Dr. Allworthy, T. F. Bell, W. McLean, T. H. McMurray, and D. W. Elliott. A committee, consisting of eight members, as follows:—D. J. Hogg, H. Hill, H. Rew, H. Crawford, J. M. Busby, P. Kilgour, J. B. Anderson, and S. McNiece McLaughlin. Mr. Cochrane continues in the dual office of honorary secretary and treasurer. Mr. John Maccomson was appointed honorary assistant secretary, and Mr. A. George honorary lanternist. The next business was the presentation of the championship cup and medals won during the past season. Mr. Hill secured the cup and gold medal for the highest average marks for prints and lantern slides, and the same gentleman also received the silver medal in the lantern slide competition. In the enlargement competition, Mr. J. B. Doran was the successful competitor, and was awarded the silver medal. Mr. H. Cochrane, jun., obtained the club's bronze

medal for enlargements. In the juniors' class for prints, Mr. H. Crawford obtained first and bronze medal. In the juniors' class for lantern slides, the bronze medal was presented to Mr. D. W. Elliott. The prints for the recent enlargement competition were on view for the inspection of members. Mr. A. R. Hogg then proceeded to give a demonstration on the "Making of Lantern Slides" by contact and reduction, thereafter showing some slides on the screen, which were obtained by various processes, including the three-colour process.

WOODFORD PHOTOGRAPHIC SOCIETY.

WEDNESDAY last saw the first meeting of the Winter Session of this Society. The proceedings were not so formal or so scientific as usual, and consisted of lantern lectures of ten minutes duration interspersed with instrumental and vocal music. Mr. Ernest Marriage, F.R.P.S. showed a short, all too short, series of his inimitable renderings of architecture, which included many fine specimens of telephotographic work, and which were much admired. Mr. W. L. F. Wastell put in a very strong plea for greater and more general use of that much abused instrument, the hand-camera. He showed a series of "snap-shots" taken on Saturday afternoons during the present summer, including waves at Hastings, scenes from rural Surrey, Epping Forest, and barges on the Thames. Mr. Wastell made his hearers laugh by holding up to obloquy a certain camera he had borrowed on one occasion, which he described as making a noise like a machine gun in winding up, thereby causing a hitherto unconscious model to look round and spoil the picture, but as this and the others taken with the same camera on the same day were amongst those that evoked the heartiest applause, we think he had little to complain of judging by results. An old campaigner like Mr Wastell should remember to wind up his shutter on another occasion before going into action. The musical portion of the evening was most enjoyable. Some fine slides by Messrs. R. and H. T. Malby were also shown.

News and Notes.

THE annual exhibition of members' work in connection with the Wearside Camera Club was opened last week. There were 150 exhibits, and the display showed a marked general improvement.

THE members of the Southampton Camera Club opened their winter programme on the 3rd inst., when Mr. W. A. Sims, of London, gave demonstrations on Rotary stripping films for three-colour photography, and with Rotary bromide printing papers.

At the South-Western Polytechnic, Manresa Road, Chelsea, S.W., a course of about twenty-five lectures, fully illustrated by demonstrations and examples of processes, on photography was commenced on Monday, October 3, by Mr. E. Senior.

THE classes in the photography and printing crafts' department of the School of Technology, Manchester, have opened for the session, 1904-5. The full syllabus may be obtained of the principal of the school, Sackville Street, Manchester.

THE winter syllabus of the photographic section of the G.E.R. Mechanics' Institute is to hand. Practically every Wednesday evening from October 5 to May 3, 1905, is filled with an interesting lecture or demonstration.

MUIRKIRK Photographic Association.—On Tuesday evening last, Mr. J. W. Eadie (Airdrie Federation lecturer) delivered an instructive lecture on "Mounts and Mounting," to the members of the association, in the Baird Institute. The lecture was illustrated with lime-light views.

HUDDESFIELD Naturalist and Photographic Society.—The opening meeting of the new sessions of the natural history section took place at the Technical College, on Saturday evening last. Mr. Wm. G. Smith, Ph.D., B.Sc., gave an excellent lecture on the "Distribution of Coniferous Trees."

THE hon. secretary of the Sheffield Photographic Society has sent us the programme of fixtures for the winter session. The items that will occupy the attention of the members from the beginning of this month to June next, promise to be exceedingly interesting and instructive.

'MR. R. J. STRUTT finds that a radio-active gas or emanation be obtained by drawing air over hot copper or bubbling it through hot or cold mercury. By repeated circulation through mercury considerable activity can be obtained of quite a different order to that of metals as ordinarily observed.

MESSRS. KODAK, LIMITED, have been favoured with the loan of a series of photographs of Macedonia, which were taken by Prof. P. N. Milnkoff during a recent tour in that country. From the negatives a collection of enlargements has been made and are on view at the Kodak Gallery, 115, Oxford Street, W.

THE Brooks-Watson Daylight Camera Co., Limited, of 119, 121, Holborn, London, W.C., informs us that owing to the success of the new "Rajar" and "Claron" specialities, they have been obliged to considerably extend their film and paper works at Moberly, Cheshire. In order to enable them to cope with the sudden increased demand they will be glad if customers will be good enough to place their orders as far in advance as possible.

MESSRS. J. EPSTEIN AND Co., of 33, Broad Street, Bristol, write as follows:—(1) Owing to great increase in our business we have taken and fitted up in the most modern style very large works at Rutland Street, Hot Street, which are fitted with electric lifts and machinery. (2) We make our frames with electric machinery and therefore, give prompt execution of orders. (3) Greatly increased stock of mouldings, which comprises hundreds of patterns all up to date. (4) New enlarged price lists will be ready the middle of October in which we are introducing several new lines.

THE announcements of the Northampton Institute, Clerkenwell, E.C., for 1904-5, include the following new developments:—Technical optics: Day courses appear for the first time, and are believed to be the first complete day courses in technical optics attempted in this or any other country. The evening classes are separated from the applied physics department and have been remodelled under Mr. S. D. Crompton, who now devotes his whole time to this work as head of the department. Artistic crafts: Day courses for these crafts also appear for the first time. The subjects taken, besides drawing and design, are goldsmiths' and jewellers' work, silversmiths' work of various kinds, engraving and decorative metal work.

"PEOPLE bother me," said Judge Addison, K.C., at the Southwark County Court on Tuesday, "to take my photograph—I suppose because I am a Judge, I can think of no other reason—and say they charge nothing; but I pay no attention to such applications." His Honor made this remark in advising a litigant not to believe that people would give something for nothing, even though they advertised to do so. When, in a subsequent case, a barrister stated that his client, although an Englishwoman, had been so mixed up with foreigners that she had either never acquired or had forgotten her native tongue, the Judge remarked that he was reminded of people he had read of in the newspapers. "They are found in the streets," he said, "having forgotten who they are, where they come from, or what language to speak."

THE Plymouth Exhibition.—The photographic section of this exhibition bids fair to exceed in popularity that of last year, when it proved to be the best thing of its kind up to then held in the West. On the present occasion the arrangements made for housing the photographic section have been amplified and increased, so that it will be presented in a better manner than before. Some of the best work will probably be represented by their finest efforts. Three classes have been added which may appeal strongly to those who may have been spending a holiday in Devon and Cornwall, those for "Devon and Cornwall Scenery," "Postcards," and the class for boys and girls in which the subject may be anything the photographer may choose. Of course, other classes have attractions also, but they have all been drawn liberally and with wide scope, so as to afford everybody an opportunity. Entries close on the 15th inst. Particulars may be found in our advertising pages.

SOUTHEND Photographic Society. — "Very ingenious" was the unanimous opinion of the members in regard to the "home-made apparatus," which formed the subject of a lecture by Mr. Fairclough on Thursday last. This gentleman must have taken an immense amount of trouble to get up the lecture and bring his bulky apparatus all the way from Leigh. His contrivances for enlarging, reducing,

and all the thousand-and-one operations of a busy photographer were explained, and proved him to be a man of many parts. On the previous Saturday, the society were booked for Hadleigh, but, owing to wet weather, did not get beyond Leigh. However, there is plenty of material there, and numerous plates were exposed on mudscapes and skylines, etc. The clouds were a great feature on this occasion, and were made the most of. The outing on Wednesday brought the season to a close for 1904, as far as outdoor work by the society is concerned.

At the Leeds Institute Technical School, classes in the principles and practice of photography will be held during the session 1904-5. Mr. S. E. Bottomley. The elementary class will meet on Wednesdays; the advanced class will meet on Fridays, commencing on September 23. On each evening an hour's lecture, with practical demonstrations, will be given at 7 p.m. It will be followed by individual practical work in the photographic laboratory (rooms D 6 and 7), from 8 to 9.30. Students who cannot afford the time for this will take the lecture course only, but no one will be allowed to take practical work alone. Fee for the lecture course only, 5s. for the session; fee for the lecture and practical work together, 12s. 6d. for the session. The course is specially arranged to meet the requirements of both amateur and professional photographers, and is intended to give them a thorough knowledge of the principles underlying the theory and practice of pure photography.

Otley Camera and Art Society.—This society, which begins its winter session this week, has an excellent programme, and there is plenty to occupy the attention of the members week by week. Out of the twenty-four lectures and demonstrations arranged, no less than fifteen are in connection with the Yorkshire Photographic Union, who send out lecturers free to the affiliated societies. Amongst the gentlemen who will speak under the auspices of the Union are Messrs. Alex. Keighley, R. Stockdale, F. W. Plews, J. Way, Percy Lund, E. Eliff, C. B. Howdill, Godfrey Bingley, F. Seaman, R. Fortune, and W. H. Atkinson, the majority of whom will deal with photographic topics. There are three trade lectures—Messrs. Wellington and Ward, Kodak, and Thornton Pickard—and lantern slides will be shown on October 13 (members), and January 19 (Y.P.U.). Interesting lectures will doubtless be those by Mr. W. Kaye on the history of printing machines, and Mr. G. R. Warnes on "Drawing and Caricature." Prizes are offered in the photographic and art sections of the society, and a circulating portfolio goes the round of the members. The meetings are held on Thursday evenings, in the Mechanics' Institute, Otley.

LECTURE ON Radium at Southampton.—"Radium" was the subject of an inaugural lecture delivered at the Hartley University College, Southampton, by the Principal (Professor Richardson, D.Sc.), on Friday last. There was a large attendance, comprising students of the college, and many others interested in scientific phenomena. Dr. Richardson, in the course of his lecture, observed that the study of matter during the last eight years had been full of surprises. The discovery of X Rays particularly marked a great advance. There was evidence to show, said Dr. Richardson, referring to radium, that that substance changed in time to helium, one of the rare gases investigated by Sir William Ramsey. Upon the first discovery of radium it was thought that it was similar to the X Rays, but examination showed that they differed in a most remarkable degree. Radioactivity was first discovered in 1896, when it was observed that rays from uranium would pass through thin sheets of metal, and that it was analogous to X Rays as regards its photographic and electrical effects. Radium, which was discovered by M. and Madame Curie, was a million times more active than uranium. It was produced from pitchblende, and the cost of one milligram (about the size of a pin's head) was £3 10s., which worked out at £99,000 per oz. the most expensive subject known. The lecturer explained the spinthariscopes. The instrument invented by Sir William Crookes, to show the effect of radium, and gave exhibitions upon a screen of the action of the instrument, by means of a model. The dream of the alchemist had, Dr. Richardson remarked, in conclusion, to a certain extent, become true. They had believed that it was possible to transform the baser metals into gold, and while this had not been brought about, it had been proved that one element, radium, changed in the course of time to another, helium. The lecture was illustrated by experiments.

WORKING UP PLATONA PRINTS.

BESIDES affording one of the most beautiful and artistic methods of photographic printing, platinum paper possesses the additional advantage of a grained surface that is easily worked up. With Platona prints, says Mr. J. I. Pigg, in "Photographic Scraps" for October, defects in the negatives due to careless or faulty manipulation can often be partially or entirely remedied by a judicious handling of the prints; clouds can be added when there is a bare expanse of sky, and obnoxious portions of a view toned down or altogether removed. If a negative prints slightly through the sky portion, leaving a tone or veil over that part of the print, clouds to suit the picture can be easily and effectively added, by gently rubbing away the deposit from portions of the sky with the finger, while the print is still wet. The platinum film will be found to come away in a granular form, instead of lifting in patches as would be the case with a carbon or silver print under this treatment. A little practice will soon make the amateur an adept at producing cirro-cumulus. If the negative is too dense to print a tone in the sky, the tint must be supplied before the print is developed. Take the printed picture out of the frame and tear a piece of brown paper so that the skyline of the picture is approximately followed; it is not necessary to be very exact in this operation. The paper is then held over the printed portion of the picture, leaving the bare sky exposed to the action of diffused light for a minute or so. The paper must be kept moving while the secondary exposure is being made, or an unsightly mark will appear on the picture where the paper was placed. The paper should be held well over the landscape and project partly into the sky, or the horizon line will be darkened. The print is developed and fixed and the clouds are added as previously mentioned, by rubbing away so much of the tinted portion as may be necessary to produce the desired effect. Lights may be added to water or any portion of the foreground, in the same manner, if the negative lacks vigour. Any black portions of the picture, such as dark corners caused by an extravagant use of the rising front, may be reduced or altogether removed by this method and if carefully carried out no trace of the working up will be visible. Only the removal of the film has so far been considered, but when portions of the picture itself require darkening the foregoing methods are obviously useless. A platinum print has almost exactly the appearance of a picture drawn with a B pencil, consequently a lead pencil of this type can be used for adding the necessary shades. The pencil must not be pressed heavily on the paper or a metallic sheen will be given to the shading. This effect can be easily seen by sharpening a pencil over a sheet of white paper; the graphite falls as dead black specks, but if the pencil is drawn firmly across the loose dust, the metallic lustre immediately appears. When comparatively large portions of the print require darkening, the pencil point must be at least a quarter of an inch in length, and cut slightly curved. The rounded edge of the curved point is laid lightly on the paper and moved gently to and fro. No lines will be visible on the print, as the extreme point of the pencil is above the paper, and a "matt surface" shading is produced without difficulty. If the pencilling is properly done the retouching is practically indistinguishable from the rest of the print even when the picture is viewed obliquely, but if pressure is exerted on the pencil the added work does not harmonize with the platinum deposit. The retouching can be fixed in the way usual with pencil drawings by dipping the picture in milk, but unless the print is likely to be roughly handled this will not be necessary. When heavy shadows require lightening, a good method is to dip the tip of the finger in French chalk and dab this on the dark parts of the picture, afterwards rubbing the chalk in with the fingers. By this means the dust is fixed in the grain of the image and a considerable improvement is effected.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION AND THE PROPOSED BENEVOLENT FUND.

To the Editors.

Gentlemen,—On Friday, October 21, the fourth annual general meeting of the above association will be held, and one item of vital importance will be brought up for consideration, viz., the proposal of Mr. H. Snowden Ward to institute a benevolent fund. Now this is a matter that no professional photographer can ignore, and there is one thing I should like to see, that every member of the P.P.A. sends in his approval of the scheme, and gives these gentlemen who are nobly doing their best for the future of professional photography the encouragement they deserve. Let them know that the association is behind them, and ready to back them up to a man. I believe the membership roll is well over 500, and I should like every one of that 500 to subscribe 5s. as a beginning. This would create a fund of about £125. Then let them subscribe 6d. per week, to be paid quarterly or half-yearly. I believe this works out at about \$650 yearly, not bad for a beginning, and it would not hurt a single one of us. Many a working-man pays as much, and more, to a sick club. I think our leaders have done splendidly with that little subscription of 5s. per year, and feel confident if photographers could see the benefit they would get by binding themselves together in one strong society, the good ship P.P.A. would weather all storms. It would be a powerful means of drawing every professional to our ranks, as he must see the advantages of belonging to such a society. I feel it would do more to curtail the system of "price cutting" than any other means, as it would create a mutual respect and brotherly feeling, now unhappily absent. And in time the Great British Public would get to know that, in dealing with a man who carried the letters M.P.P.A. behind his name, they were doing the best for themselves in every way, those letters meaning he was a member of an honourable society of gentlemen, a society instituted for the upholding of photography as a business and an art. Now, photographers, "altogether, please."

FRANK WATSON.

Brighton,

October 3, 1904.

[A very practical and encouraging letter—one of a kind of which we should like to see more from our professional readers who are, or should be, interested in the proposed benevolent fund. With regard to the suggestion that the P.P.A. should take the matter in hand, we may be pardoned for pointing out that the idea is by no means new. At the inaugural meeting of the association on March 23, 1901 (see this Journal, Vol. XLVIII., p. 215), the chairman, Mr. Thomas Bedding, F.R.P.S., observed, inter alia, "Such a body as your proposed association, it seems to me, forms the best agency for tackling a question like this." As we have over and over again remarked let photographers themselves once stir in the matter and the benevolent fund will not long lack the support of the photographic world.—Ed. B.J.P.]

NOTHING LIKE BUTTONS.

To the Editors.

Gentlemen,—We think the enclosed letter so replete with unconscious humour as to be deserving of having extracts from it published in your journal. We appeal to you, can nothing be done to avert the horrible doom that awaits us, or must we, indeed, succumb to our fate, and relinquishing all our ideals, henceforth consolidate our interests in the "button business," and become "button manufacturers"? Taken seriously, are we to regard this as one of the numerous ominous signs of professional decadence, and as an additional proof of the low level to which photography as a profession is sinking? Here we have the high-art photographers, who are yet not above "touting," and who write continually to the best people (one lady assured us she had received about a dozen letters) begging the favour of a sitting, free, and proof submitted; while in the principal

streets there are numerous "three retouched cabinets for half a crown," artists, and gentlemen who supply twelve promenades for 7s. 6d. 10s. 6d. Our "Evening Echo" produces a permanent enlargement 5s. 6d., and a large general store is advertising twelve postcards any photograph, 2s., sittings 1s. extra. No wonder that clients little value on photographic portraiture and constantly tell us it is "all profit" in photography. It can hardly be a matter for surprise that assistants find their salaries decreasing, that "sweating" is prevalent, or that your advertising columns contain so many notices "businesses for sale."—We are, yours truly,

29, Bold Street, Liverpool.

MEDRINGTON'S, L.

October 4, 1904.

The following is extracted from the letter referred to:—

"Your name and address were given us by our consular office, your city, and at his suggestion we mailed you our catalogue, list, and samples. We also wrote you extensively and tried to draw your interest in the button business. Inquiring the reason why you have failed to hear from you is the main object of this letter. As a photographer, one of not several branches of our industry shall appeal to you, as it is one of the most ingenious applications of photography ever made.

"Several chemical ingredients have been looked for to lengthen the life of a picture. Many expensive solutions were prepared to preserve the products of photographic art. Our formula is the easiest, cheapest, and most effective we know of. Celluloid is the name. Celluloid is the base of our industry. We copy pictures, mount them under celluloid by means of heat, mount them into any button or medallion, illustrated in the catalogue. We also insert into brooches, charms, bracelets, lockets, in different sizes, qualities, and designs. A plain or tinted picture united to the celluloid and in a frame, charm, etc., makes a neat and up-to-date jewel, universally by people of different ranks. We sell celluloid, by parts, jewellery, and all the material required. Also the machinery which will wonderfully transform all this material into beautiful buttons, medallions, etc., by simply following the instructions furnished every manufacturer that we start. It is our desire that become a button manufacturer; sooner or later you will have become one in order to hold your trade and keep your rank as one of the photographers who have already created the demand for our goods.

PHOTO JEWELRY MFG. CO.

Chicago, September 22, 1904."

[Our correspondents take, we think, an unwarrantably pessimistic view of the present condition of professional photography, although there is no doubt that, as the phrase goes, it is very much "cut" just now, and suffers from its full share of the prevalent commercial depression. But there is, in our observation, a rapidly growing appreciation of the work of such men as Crooke, Hollyer, Barrow, William Gill, J. Craig Arran, Furley Lewis, Histed, T. C. Turner, and many others whom we could name, which augurs well for the future of the art, if we may so designate it. In photography, as in everything else, it is the fittest that survives. On our table as we write are many crude specimens of portraiture, sent to us for our criticism and opinion. They possess every possible fault of which photography is capable and none of its excellencies. Vast quantities of such are supplied to the public day by day all over the land. Is it to be wondered at that in these times of high mental and artistic development such abominations should provoke disgust and contempt? There is no room to-day for the incompetent and illiterate dabbler who establishes himself in a frowzy tenement in a mean street; the educational influences of the sumptuously illustrated publications that have come from the press have been at work, and his doom is sealed. We honestly believe that if the present magnificent exhibition of photography at the New Gallery, Regent Street, were visited, not by the paltry or eleven thousand persons it at present attracts, but by the workers of the educated classes, there would be such a demand for the kind of work there shown that a new era of prosperity would set in. The public knows a good thing when it sees it; but, as we hinted a few weeks back in reply to a complaining correspondent, it will have mediocrity at any price. And it is the mediocre photographer who is going, and must go, to the wall.—Eds. B.J.P.]

WANTED! A GOOD PHOTOGRAPHIC PAPER.

To the Editors.

Gentlemen,—Probably many will say on reading this heading, "there are too many already." After forty years' experience

photographer, and during that time having experimented with almost every kind of material and paper for photographic printing, I still regard the ideal paper for simplicity in working, the correct rendering of detail of a good negative and permanence is yet to be produced. I would combine the simplicity and permanence of platinum with the rich detail of collodio chloride, the speed of bromide, the colours of carbon, and the cheapness of albumenised, we should be near the mark. The subject is a very exhaustive one, but it is my intention simply to mention a few photographic papers and their characteristics. Albumenised paper must be freshly sensitised day by day, as it will not keep well. Is slow to print, blisters badly, requires toning, shadows bronzing, stretches and distorts, is not permanent under all conditions, fairly hard surface standing rough usage, is easily dried and mounted, and is cheap.

The commercial article is often made with decomposed albumen, which accentuates its bad qualities.

Gelatine chloride can be obtained ready for use, prints fairly quick, is so easy to handle, surface being tender, very uncertain in toning, heavy shadows even to bronzing, cannot be dried quickly, keeps better than albumenised, and does not stretch so much; is not permanent though popular; rather low in the scale of photographic papers.

Bromide.—Sold ready for use, prints very quickly, troublesome dark-room development, fine detail in some brands, in others heavy shadows; good keeping qualities, colour rather objectionable, surface tender and liable to abrasion, fairly permanent, much more so than either of the foregoing; useful for either thin or dense negatives; not paper for general use.

There are several children belonging to the bromide family some of whom are popular with amateurs. A good range of colours can be obtained by troublesome methods.

Collodio Chloride.—Several varieties sold ready for use. Prints well. Bright rich image, beautiful detail, making it most suitable for photographs from which to obtain half-tone process blocks. Has a hard waxy surface, is difficult to tone with gold, easy with salt. It curls and cracks dreadfully, liable to blister. It will not keep long; turns yellow. Is not permanent, or rather not uniformly so; some brands turn out well, others show yellow fading quickly. Is not easy to mount. This paper has many good points, and would become very popular if the curling, cracking, and blistering faults could be overcome and the price be lowered.

Carbon.—Difficult to print, troublesome in the after process, tissues liable to tear, detail good, best range of colours; permanent.

As at present not altogether suitable for every-day use, but in this direction I think must be looked for the paper of the future.

Platinum.—A beautiful paper, prints fairly quick, difficult to judge when done, easily developed, quickly washed, no great length of time required in its manipulation. Its colour beautiful when at its best, with rich plum-like bloom; permanent. One of its weaknesses is the tendency to attract moisture; keeps well in air-tight tins in a dry place. When sepia developed it is one of the finest papers in the hands of the photographer for artistic purposes, but not so suitable for reproduction.

All things considered platinum holds the premier place in my judgment amongst photographic papers at the present time.

It might have been better if this were headed: "Wanted, two Photographic Papers." We must retain platinum, and for the other, the same ease in working but giving all the sharp points of the negative. No doubt there are many who will defend the good name of the papers mentioned, and I do not say good results cannot be obtained with each, but still I am of opinion we want an ideal photographic paper.—I am, yours, etc.,

Cambridge, October 2, 1904.

J. C. BURROW, F.R.P.S.

[Mr. Burrow's long practical experience entitles him to be heard on this subject, but we are bound to rejoice that his ideal printing paper is not likely to be placed on the market until photographic chemistry has become something altogether different from what it is. Ideals vary with individuals; cannot Mr. Burrow conceive that each of the printing processes he criticises amply meets the needs of many workers in photography? *Chacun à son goût!*—Eds. B.J.P.]

SPOTS ON C.C. PAPER.

To the Editors.

Gentlemen.—The trouble with spots which many of your correspondents experience in working C.C. paper may be avoided by drying the prints quickly after mounting, either before a fire or in a proper

drying cupboard; it is better to let them stand half an hour before drying them, and not to use too much heat, else they will curl off at the edges. The cause of the spots is fermentation. They never appear on unmounted prints. The quick drying of the prints seems to add to their brilliancy. It is important that every trace of the strongly acid platinum toning be washed out before the hypo bath.—Yours truly,

T. FITZGIBBON-FORDE.

15, Waterloo Place, Sunderland.

September 30th, 1904.

SUNDAY WORK.

To the Editors.

Gentlemen,—Please allow space for the following, and I will be much obliged. I see that "Sunday work advertisements" are on the increase. Let us look at the matter from two points. The proprietor is greedy, he wants seven days a week for himself and cares little or nothing for his God's claims on him. Further, the proprietor is selfish, he does not consider his workers. The proprietor is also foolish. Solomon says, "He that hasteth to be rich hath an evil eye, and considereth not that poverty shall come upon him"—Proverbs xxviii., 22. It is no use arguing, for facts, as well as right, is against such a proprietor. Very early in the world's history our Creator orders one day a week rest. I have spoken to "seven day" workers, and have always found them to a more or less extent, irritable, tired, "run down" in health, and inclined to be slovenly, etc., in business, etc., etc. The One who made us knew best what the human machine would stand, and that the brain needed to be rested and the nerves relaxed. He is all-wise. Seven-day workers are foolish. Even an inanimate thing, such as a razor, works better for a period of rest.

Let us look at it from the assistant's point of view. Competition and over-stocked labour market lead many with weak principles to engage themselves to "seven-day-a-week" employers. They get into a commoner class of trade and generally degenerate into "wasters." For "whatsoever a man (or woman) soweth, that shall he (or she) also reap." "Be not deceived." "God is not mocked"—Gal. vi., 7.

The difficulty is to get any remedy for the "bad place." It will be dealt with, however, at the "judgment"—Revelation xx., 11. In the meantime, let me ask those employers mentioned to be wise, merciful, and less greedy; and that assistants may, for their own sakes, give "seven-day-a-week" ads. a wide berth.

S. H. WRIGHTSON.

Sunnyside, Kirkley Park Road, Lowestoft.

September 30th, 1904.

[The question of Sunday work can, we think, be discussed without reference to religious considerations, which probably weigh little with the majority of people nowadays. To be logical, our correspondent should stop locomotion, close all shops, and forbid every kind of amusement and entertainment on Sundays. We do not seek to defend the practice of photography on the first day of the week, but it is perhaps permissible to speculate that "the day that comes between a Saturday and Monday" affords the only opportunity for many persons to indulge in the harmless occupation of being photographed. And after all, if an assistant has conscientious scruples in the matter, he need not engage himself to an employer of Sunday labour. We do not invite further letters on this subject, which was fully discussed a few years ago in the Journal.—Eds. B.J.P.]

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

- P. Charleton & Son, Garrison Studio, Newbridge, County Kildare, Ireland. Three Photographs of Drum Horse, 11th Hussars.
- G. A. Seaman, Pelham Street, Ilkeston, Derbyshire. Photograph of Shipley Hall, near Derby.
- H. Lowthian, 144 and 146, Freeman Street, Glimshy. Photograph of St. Andrew's Church, Glimshy.
- J. E. Reeves, 18 and 50, Hermit Road, Canning Town, London. T. Alison, F. Piercey, W. McCartney, D. Gardner, J. Flynn, C. Sammons, J. Fletcher, W. Bridgman, T. Bartlett and M. Kingsley, all of the West Ham United Football Club.
- H. L. Fry, The Rectory, Ballyvaunlon, County Kerry, Ireland. Photograph of Ballyvaunlon R.C. Church.

F. H. P.—The specimen of retouching sent is very good of its kind.

ADDRESS WANTED.—"HYDER" says: "In 'Ex Cathedra,' September 2, you give an account of railway station lighted with acetylene, can you tell me where I can get further information re dry generation of acetylene gas from calcium carbide?" In reply: See answer to "J. C. W." in last week's issue.

W. SYDNEY TAYLOR writes: "I should be greatly obliged if you could kindly inform me how to become a member of the Royal Photographic Society?" In reply: If you write to the secretary, Mr. A. W. W. Bartlett, 66, Russell Square, London, W.C., full particulars will be supplied you.

OLD NEGATIVES.—"E. S." says: "I have a great many old waste 12 by 10, 10 by 8, 1-1, $\frac{1}{2}$, and $\frac{1}{4}$ negatives. Could you inform me if there are any firms who buy waste glass of this sort, and whether it is worth the carriage?" In reply: No. The glass is not worth the trouble of cleaning for recoating. Did you read the article on the sale of negatives in our last issue?

BURNISHER.—J. HIPGRAVE says: "I am sending you two rough prints of a burnisher I bought at a sale a few days ago. Will you kindly explain how it is used, where I could get the bar polished, what A is for, and if it is any use at all?" In reply: It seems to be an ordinary bar burnisher. Any of the dealer's will, no doubt, get the bar re-polished for you.

PRINTS ON CELLULOID.—H. MOORE writes: "I am informed that 'celluloid positives' can be obtained for the basis of miniatures. Can you tell me anything of the process, or where I could get some done? I have a demand for cheap miniatures and the carbon transfer on ivory is too expensive." In reply: Carbon prints can be produced on celluloid in the same way as they are on ivory, and the celluloid would be much cheaper.

GAS HEATING.—"GAS STOVE" asks: "Will you kindly say if you know of any small gas stove on the market suitable for heating a small dark room, one that gives out no light; perhaps you know of something better?" In reply: Messrs. Fletcher and Co., 134, Queen Victoria Street, and Warrington, have a great variety of gas-heating stoves, some of which give little or no light. Write to them for a prospectus.

MATT PAPER.—F. ESSOM asks: "Will you kindly give me a good formula for matt surface P.O.P., or tell me in what way it differs from the glossy P.O.P.?" In reply: The difference is that the one has a glossy and the other a matt surface. We must confess we are not in the secrets of the matt-surface paper-makers. Even if we were, we fancy they would not like us to publish them for the benefit of other makers.

STAINED PRINTS.—T. RIDOUT asks: "Will you kindly inform me the cause of stain on the enclosed print? I have had whole

batches like it, although the dishes are well cleaned. It occurs with various makes of P.O.P. These stains appear to be affected by light, and some of them only appear when dried. In reply: The cause of the stains, we should have thought, would have been obvious to any photographer. The prints are only fixed round the edges. They have been allowed to dry together in the fixing bath so that the hypo has not had an action.

VARIOUS QUERIES.—"DAMP" writes (and we reproduce his queries verbatim et literatim): "(1) I have a 1-1 plate lens and looking at the glasses of it you can see it full of a kind of spots or damp and some by looking through it. Will they do any harm, or can they be cleaned off? (2) What is the best way to hold a ball of the shutter of a camera, to not bust it when releasing it?" In reply: (1) If the spots are superficial they can be cleaned off with a slightly moist piece of chamois leather; if they are not superficial better have the lens recombed by a working optician. (2) Dear man, do not try the effect of holding it not too firmly in your right hand?

STUDIO QUERY.—"OPERATOR" says: "I should esteem it a favor if you would enlighten me on the following:—I wish to build a studio in the garden as shown in plan. Is it possible to do good work under such circumstances? What would be the best form of studio to build, the light on the left is unobstructed, but would be troubled with the sun, on the right the church cuts off the north?" In reply: A very useful studio could be erected on the ground as shown in the sketch. Of course, the sun would be on it towards the after-part of the day, but blinds will remedy that. We should recommend you to get Bolas' book, "The Photographic Studio"—a guide to its construction. That will give you much useful information.

DISPUTED QUALITY.—"A. J. L." says: "I bought a camera complete with lens, and paid £13 5s. cash for same. The lens did not answer my purpose, so I asked the firm to exchange it (the lens for a better one, which they agreed to do. They had not the lens I required in stock, but recommended me one which they said would suit me, and would let me have the same on trial for two weeks if I paid the price of lens, viz., £8 16s., as security. This I did, and found the lens was no use to me, so I returned it in one week. They now refuse to refund the cash, say they only agreed to exchange it. Your advice on the subject will be greatly esteemed." In reply: We take it that if you can prove the lens to be qualitatively bad your remedy would lie in the County Court. But your complaint is very vague.

ARC LIGHT IN LANTERN.—"PHOTOPHIL" says: "(1) I should be much obliged for some hints about the management of hand-fed arc lamps, I find it difficult to maintain uniform position of the carbons, and do not quite find out what is the best position for projection working at about 20 amperes; with 20 amperes I get a five-metre picture by transparency not too well illuminated in well-lighted street. Shall be grateful for advice." (2) What is the best way to avoid fracture of condenser tubes frequent?" In reply: (1) If you have a good arc lamp, such as is now supplied with the best lanterns, there will be no difficulty in the adjustment of the light. Every provision that is made. We should advise you to get such a lamp. The best way is to have a good current of air through the lantern so as to carry off the excessive heat; also not to expose the condenser suddenly to cold air.

RIGHT TO EXHIBIT PORTRAITS.—"PUZZLED" writes as follows: "I shall be glad if you can give me your opinion on the following case: A gentleman brought his children to my studio to be photographed. I took eight negatives of them, two of each in four positions, group of two. I submitted rough proofs of seven, which were good, at his request, and he selected four and then asked me to sell him those four, which I did. I afterwards made an enlargement from one of the negatives left in my hands, and made certain introductions into the picture and exhibited this in my window. Now this gentleman is writing and asking me to give him this picture as he states it is not my property, and I had no right to do this, as his objection in buying the negatives was to prevent my showing them all." In reply: You have no right to do what you have done. You have rendered yourself liable to law proceedings by exhibiting the picture against the father's wish. Better withdraw it at once.

NEW BOOK	900

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

Forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,604 pages, the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose continuing the volume for 1905. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to readers as susceptible of improvement.

The ALMANAC for 1905 will appeal to photographers all over the world as a daily reference guide in practical work. Standard matter and formulae will be revised and added to where necessary; the year's advances in theory and practice will be recorded.

The frontispiece of the ALMANAC will consist of a portrait study specially taken by Mr. Furley Lewis of the Royal Photographic Society's Exhibition, 1904.

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies. We shall also be

glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc.

The publishers ask us to remind advertisers that a large proportion of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion, order and copy should reach them not later than Tuesday next, October 18.

*. IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that this year the entire edition of the ALMANAC (25,000 copies) will be placed in the hands of dealers and the trade on December 1st next—a fortnight earlier than usual, so as to be well in advance of the Christmas publication season.

EX CATHEDRA.

Lithium in Photography. According to a report of the United States Geological Survey, the production of lithium salts in the present year will considerably exceed that of any of the last year or two, and with a larger demand for lithium compounds they may be marketed at prices which place them more nearly in the category of common chemicals than in that of laboratory compounds. Caustic lithia, or lithium hydroxide, to give it its chemical name, has been recommended more than once as a substitute for the common and infinitely cheaper alkalis, soda and potash in developers. But the advantages have not been convincing, questions of price even separated from the comparison. In one particular only can lithia boast of superiority over the well-known alkalis, and that is in the preparation of a highly-concentrated single-solution developer. The atomic weight of lithium is the smallest of any of the ordinary metals, viz., 7, and so 24 parts of lithia will do the chemical work of 40 parts of caustic soda or 56 parts of caustic potash. To balance this advantage, lithia is not quite as soluble as these alkalis, but the difference is not enough to bring down the energy-giving properties of the substance to the level of these others. Sarbe, in the "Almanac" a few years ago, put it down as doing the work of twice its weight of soda and of three times its weight of potash, figures which are not a great way out from those given on purely chemical grounds.

* * *

The Advent of Cold Weather.

The spell of cold weather we have had the past week has been sufficient to remind us that winter is fast approaching. Already the depressed temperature has a marked effect on the development of plates where the solutions have been allowed to remain in cold, dark rooms, and may lead many workers with limited experience to imagine that their plates have been under-exposed, while, as a matter of fact,

such may not be the case. A sudden depression of temperature would, of course, not mislead an experienced hand, but it may novices, many of whom may now be setting about developing the plates exposed during the autumn holiday. With them, in many instances, the dark room is not artificially heated, and if the room is in an exposed situation, as is frequently the case, and the solutions are kept there, they get very cold. The consequence is the image is very tardy in making its first appearance, and thus often leads the novice to imagine that the plates are under-exposed (and are dealt with as such), while they are nothing of the kind, the exposure having been ample. A word to those who have plates yet to be developed is to keep the solutions where they will be at a temperature of not less than 60 Fahr., and to employ water in their dilution of not less than that. In this way they will not be misled in their work by the long time the image takes in making its appearance and in gaining the requisite density.

German Dry Plates.

It really seems as if our German friends were many years behind us in most points connected with the dry plate. In a recent number of the "Photographische Industrie" is a leading article headed "Thinner Glass for Dry Plates for the Hand Camera." How long is it since English manufacturers satisfied this demand of the English amateur photographer? We are now so accustomed to the thin quarter-plate, and so fully appreciate its lighter weight, that the manufacturer who returned to the thicker glass of former times would find a sensible diminution in his returns. Yet, according to the article we have mentioned, photographers in Germany have to use imported plates if they want them of light weight. It appears that the average thickness in Germany of a dozen 9 by 12c plates is 24 m.m. This is the size used abroad instead of the quarter-plate. We have just taken hap-hazard a dozen quarter-plate negatives, and find the total thickness is 17 m.m. It follows from this that the German has to carry in plates half as much weight again as his English colleague. But this is not the only disadvantage. The price of the German dry plate is about 50 per cent. higher, and therefore the English photographer for the same amount of money gets 50 per cent. more plates without adding to the weight he has to carry, if we compare him with his German confrère. Something might be said in regard to speed, too. In explanation of this difference it may be remarked that there is an import duty upon dry plates in Germany to protect the manufacture of glass. But although the photographers pay this duty, it does not appear to bring them any corresponding advantage.

Photography and Art.

On July 8 we published a translation of a paper by Dr. Reiss, which has attracted general attention. On October 7 we also published a reply by M. Liegard, so that our readers might have an opportunity of studying both sides of the question. M. Liegard quotes from M. René Le Begue, and thinks he has found an answer to Dr. Reiss's flagellation of the ultra school in the words: "It is not the process that should be criticised, but those who do not know how to use it." We need scarcely point out that this refers to gum-bichromates, and we desire to remark that if the question is permitted to rest here, the discussion is only a verbal one, and that M. Liegard is in actual agreement with Dr. Reiss. Dr. Reiss instanced the abuses of some of the workers in gum-bichromate, who, by adopting the medium of some expert photographers of taste, and imitating, or exaggerating, their style, regardless of its suitability, wished to

attribute the quality of art to their trickery. But the question remains, can a work, which has been developed with a brush, or some means which gives us the artistic impression, be called a photograph? Dr. Reiss wisely calls the attention of the photographer to the question whether it is expedient under such circumstances to give the preponderating power to painters and sculptors in the constitution of a jury for a photographic exhibition. If such a jury is to give a verdict concerning pictures which are supposed to be the effect of light, surely preference should be given to men who make such judgements, and who have the capacity to appreciate æsthetic qualities. The two qualifications should be separated, and it is a mistake, which Dr. Reiss justly protests against, to minimise the voice of the photographer in the estimation of his own branch of work.

Photography of Bird-Life.

All that is beautiful in this fair corner of ours we jealously guard as our national heritage, and photographers are among the first to resent any action which tends to destroy or diminish the charms which cling to the rustic scene. Of late years, the work of the naturalist has been much aided by the camera, and there are many patient students whose delight it is to spend hours in tracking rare and timid birds to their isolated nests, so that they can, unobserved, get photographs of them as they are "at home." In a lecture recently given by one of these photographic naturalists, much indignation was expressed by him at the ruthless manner in which some of these wild birds are slaughtered for the sake of gain. And it is a matter of common knowledge that if some bird of a rare kind makes any attempt to settle in the country, he does so at the risk of being shot, either by a gamekeeper or by a collector. So it comes about that for every lover of nature who does his best to defend birds from injury there are dozens of interested persons who compass their extermination. We may suppose that tender-hearted ladies would be the first to resent the suggestion that they are principally responsible for the slaughter which goes on, but it is a fact that if they do not encourage the fashion by wearing birds, and parts of birds, in their headgear the market demand for the bodies of these poor feathered bipeds would cease, and the birds would be left alone. We may be sure that in this case "evil is wrought by want of thought," rather than by want of heart, and if our photographic friends who love birds would hint to their womenfolk the cruelties which are committed in order to meet the demands of a vain and senseless fashion, much good would accrue to our native warblers, as well as to the numberless birds of foreign origin which at present fall victims to the traders' guns.

* * *

Discovery of Old Masters' Work.

More than once of late we have referred to the fact that there are, probably, at the present time a goodly number of valuable pictures by the old masters possessed by people who have no idea of their commercial value, and do not at all appreciate them as pictures. Some ignorant people in country places, for example, would even give place to them not knowing the value—to a genuine Vandyck, or other old master, for a common "chromo" with plenty of vivid colour. Hence many good works become lost—consigned to the loft, or perhaps destroyed. It was reported last week that the two ancient paintings recently discovered in the old Roman Catholic Cathedral at Leeds are by Rubens and Vandyck, and that the broker who bought them for a few shillings has been offered, by two different dealers, 2,000 gs. for them. This sum has, so it is stated, been refused, as the pictures will be put into an approach

London sale, when he expects to realise £8,000 or £9,000 for them. It is further stated that whatever sum the pictures may fetch, 25 per cent. of it will be handed over to the Roman Catholic community in connection with the Cathedral. Be all this as it may, there is little doubt that there are now in existence many very valuable pictures stowed or hidden away because their owners do not appreciate them and have no idea of what is their market value. A few years ago a friend of ours bought at the Islington Friday market an old dirty oil painting for a trifle—half-a-crown, if we remember rightly. A week or two afterwards a picture-dealer offered him five-and-thirty guineas for it in its then state. This serves as a practical illustration of how valuable works are sometimes dealt with through the ignorance of those into whose hands they may fall.

* * *

Who is to Blame?

It was a large, illustrated work of undoubted value, published by a firm of wide repute, and the photographer who invited our attention to it was an expert hand. He asked us if we had ever seen worse half-tone blocks in a book of such high pretensions, and we had to confess that we had not. This conversation naturally led us to think about blocks generally and the way in which the advent of process had completely revolutionised the methods of the printer and publisher. And we endeavoured to find out the reason why the illustrations in the volume referred to were so inferior. We knew well enough that if it had been in our power to make inquiries at headquarters the author would have blamed the block-maker, the block-maker would have blamed the printer, the printer would have abused the ink, and the ink manufacturer would have traced the fault to the paper. The scapegoats would have been many, while the probability is that no one of them was particularly at fault. Where, then, should we find the culprit? It is a question that does not affect this one firm alone, but is of grave importance to many other long-established businesses, and is therefore worthy of grave attention. The reason for the defection is summed up in three words, "antiquated printing-presses." When the half-tone, or Meisenbach block, as it was then called, was first introduced the printers regarded it as an impossible thing—an attempt to supersede wood-engraving which could never succeed. Such shallow lines and microscopic details seemed to be ridiculous, and it was no matter for wonder that the ink quickly filled up the delicate interstices of the block, and an unsightly impression was the inevitable result. But the block-makers knew that they were right and that the printers were wrong. Instead of making bolder blocks they made still finer ones, and soon proved that if ink and paper were of the right kind the half-tone blocks would do good work. Then it was that more attention was paid to the press itself. The excellent presses which had been used up to that time for type and comparatively coarse wood blocks would not respond to the needs of the half-tone block. Happily, the improvements which had been gradually evolved in mechanical contrivances generally came also to the printing-press, and modes of adjustment of pressure, distribution of ink, and so forth were adapted which were not dreamt of in the philosophy of the printers' devil up to this time. Hence the modern, up-to-date printing-press is far in advance of anything known twenty years ago, when the half-tone block first came to be seriously considered by publishers, and he who would produce the best work must give up the old and adopt the new contrivances. It is, of course, a serious undertaking for a large printing-office, founded perhaps three decades back, with the most perfect appliances then to be obtained, to throw its machines into

the scrap heap and to buy new. This, we are told, is constantly being done in America, not only in the printing trade, but in every other industry dependent upon mechanical contrivances, and this is one of the reasons why American methods and products are so successful. The printer of to-day, if he would take full advantage of all that photographic process has done for him, must set his house in order.

* * *

Fashions and Photography.

Some time ago we noted with satisfaction and interest that the drawings of the human form divine, with their eccentric anatomy, which had hitherto served as "fashion plates" were being gradually superseded by photographs from the living model. And we congratulate society upon the change, for wasp-like waists and other deformities, brought about by the abuse of the corset, are not to our liking, and are opposed to everything that savours of Art. Besides, some of these photographs are really masterpieces of their kind, and we understand that in Paris a regular system has been established by which the best dressmakers, the best photographers, and girls with the best figures work in concert, with the result that artistic pictures of the latest modes are sent broadcast over the world with the least possible delay. In this way the shopkeepers are able to place before their clients the very newest confections. These photographs have probably been the means of educating the public into a desire for better things in the way of fashion drawings than they were content with a few years ago, and we find a notable improvement all round in the representations of bedecked femininity which adorn the catalogues of the leading costumiers and the various journals which devote themselves to the service of the fair sex. For drawings are still largely used for fashion work, in spite of the rivalry of the camera, and from what we can learn from an authoritative source they are not likely to be soon displaced. The reason for this adherence to an old custom does not arise from any prejudice against the camera; indeed, our informant, a lady who has for years been a fashion artist, made no secret of her admiration for many of these photographs. She praised the pose, the lighting, and the general arrangement, and considered that in these aspects they were beyond reproach. But she pointed out that a milliner who attempted to work from these pictures would find herself sorely handicapped, for in many of them the detail in the trimming and the laces is quite lost. In other words, the photograph is too good as a picture to be serviceable as a model. It would seem, therefore, that the ideal fashion drawing is one in which the anatomy of the figure shall not be distorted, but that it must be strictly up-to-date, and that the detail must be such that both design and texture of material is adequately rendered. It must, in short, be pleasing to the educated eye, while at the same time it must have the exactitude of a working drawing. The conclusion of the whole matter is that photography can no more supplant the best fashion drawing than it can hope to replace the working drawing of a bridge, a locomotive, or any other engineering enterprise. To show the general effect of a costume it is excellent, but for actual details which the worker requires it is found wanting.

* * *

Lantern Lamps.

The societies in different parts of the kingdom are now commencing their winter session, and there is little question that the lantern will be largely in evidence with them during the coming season, notwithstanding that it has been alleged that its popularity is waning. Without the lantern it is a little difficult to see how many societies would find pabulum for their meetings. At most of the societies the lanterns are

furnished with the limelight, but the lanterns of the members, which they employ at home as a rule, are not; with them oil is the usual source of light, and it is with them we are now dealing. They were laid aside at the end of last season, and it would be a safe speculation to say that a very large proportion of them were put away just in the state in which they were last used, with the result that when next employed, unless some work is done to them, they will emit malodorous fumes that will make themselves exceedingly unpleasant throughout the house. A hint or two on the treatment of lamps in the state of those just referred to will, we know, be useful to many who neglected to take the precaution of emptying and thoroughly cleaning them at the close of last season. In the first place, the wicks should be removed and thrown away, as they will be of no further use if smell is to be avoided. Then the oil should be thoroughly drained out of the reservoir, well rinsed out once or twice with fresh paraffin or benzoline. The outside as well as the wick tubes should also be well cleaned with the same material. It is well to finish the cleansing with benzoline, because it evaporates quickly and leaves the parts dry. New wicks must now be provided. These should be selected with care that they accurately fit the burners, and before they are put in they should be baked in the kitchen oven for a time so as to drive away all trace of moisture. Wicks so treated will last much longer than those which are not. The trimming of new wicks is of some importance, as it materially influences their life and also the brilliancy of the light. When first put in they should be cut with scissors level with the tops of the burners. Then the wicks should be racked up for the sixteenth of an inch or so and lighted, and allowed to burn themselves out; this will secure a proper burning level. The reservoir may now be filled with oil, and allowed to stand until the wicks are completely saturated, and no attempt should be made to light them until they are. If the lamps are treated according to the above hints they will be found to work as well as they did when first supplied by their makers. When wicks are perfectly fitted and levelled, in the first instance they should never again require scissors treatment, simply wiping off the ash being sufficient. One frequently hears such exclamations as this, "I hate oil lamps, they stink so." With a good oil lamp, such as is now supplied with lanterns at quite moderate prices, we venture to say that in nine cases out of ten the "stink" is due to want of cleanliness on the part of the user. Stale oil is allowed to remain on the outside of the cistern and the wick holders, or the wicks are not carefully attended to. All parts of the lamp, wick holders included, should be carefully wiped with a dry cloth just before the lamp is lighted for use, and when these little matters are attended to no unpleasant emanations will be experienced.

MR. A. L. HENDERSON informs us that he would like to know of a few photographers, professional or amateur, who would join him, during this winter, for a tour in Palestine, preferably under the auspices of Cook and Sons. Address, after October 20, care of Cook and Son, Nice, South France.

DEATH FROM X-RAYS.—The "Standard's" New York correspondent, telegraphing one day last week, says:—"Mr. Dally, who was formerly Mr. Edison's assistant in his fluoroscope experiments, died yesterday, after seven years of torture resulting from exposure to X-rays. His hands developed red patches, like scalds, which were at first painless, but refused to heal. Eventually cancer appeared, necessitating frequent amputations of the fingers and hands, and finally of both arms. The stumps caused such suffering that he was only able to sleep by immersing them in troughs filled with water. Nothing that skill or money could do gave him any permanent relief. His case had been observed with interest throughout the medical world."

SUPPLEMENTARY LENSES.

It is somewhat singular that so little attention has been given to the subject of supplementary lenses for altering the working focus of an achromatic objective of possibly expensive construction. It is not necessary for us to remark that many hand-cameras have for some time past been supplied with these additions, often under the name of magnifiers, though why "magnifiers," seeing that, at any rate, their usual function as applied to a camera is to diminish instead of increasing the size of the image? Of course, it is equally possible to use a "supplementary" to increase the size; but it is not a usual form, and certainly not to a fixed-focus camera. When used with a hand-camera their function is generally to permit a fixed-focus instrument to be used satisfactorily for objects between the distance point and the camera; that is to say, for objects so near to the worker that with the fixed focus they would give an absolutely useless image, utterly blurred, and unfit even for a disciple of the fuzzy-type school. With a set of these additional lenses a range of possible distances from the camera, varying from three or four up to twenty feet, may be utilised. A possible drawback to their more general employment is the circumstance of their being generally made use of for portrait work, when no stop would be inserted, as the largest possible aperture of the lens would, for the sake of rapidity, usually be employed. Then the conditions—open aperture and a near object—would necessitate a thorough nicety of focussing or extreme accuracy of placing the object at the correct distance from the camera, as at these distances an object is so quickly put out of focus. When a stop is used, it need scarcely be said that such nicety of position is not necessary—to a greater or less extent as the stop is larger or smaller.

With regard to these magnifiers—they do act as magnifiers when an object is examined through them as an aid to vision—it should be observed that it is not, for the class of work we refer to, necessary to employ expensive lenses. We do not profess to have examined those supplied to every instrument in the market to which they have been adapted; but this we do know, that all practical purposes are subserved by an ordinary eyeglass, and if a circular form be preferred, as the usual ovals are awkward to handle, and represent but a small circle when trimmed or screened to a circle (though at an emergency they may be employed unaltered), one can be purchased at a working optician's for mere coppers. The question naturally arises, if a lens of sufficient importance to do the work we allude to does not require to be of an expensive character, why use a costly lens at all? And we must leave it at that. Our remarks are not part of a treatise on optics; they are merely for the purpose of drawing attention to neglected opportunities and our readers may rest assured that for ordinary hand-camera work these cheap additions are of practical usefulness.

But there comes also another aspect of the subject. Many photographers possessing a focussing camera can afford but one good lens, and occasions arise when its limitations are troublesome. It is wanted to take a photograph of a spot or an object so close that when it is attempted to focus, the camera is found not to rack out far enough, with the result either that the work is left undone or the scale of reproduction is disappointingly small. A new lens cannot be afforded, but if a supplementary convex lens be used the difficulty is subdued at once. Again, a particular view is wanted, but from the only available standpoint it takes up such a small space on the plate that it is felt to be not worth while to waste an exposure. A telephoto or an Adon even is beyond the pocket of the photographer. If his lens be of the double type he may unscrew back or front and take a picture double the size (more or less). But the

type of lens fitted to the camera may be an achromatic landscape, which cannot be halved, or it may be found when the lens is halved that the utmost possible extension of the camera is not sufficient for the new focus; this happens with a popular camera and lens of a well-known type. But once more a supplementary lens will find its place. If a concave of the right focus be used a view may be taken at the utmost extension the camera will give, and its size will of course be exactly in proportion to the increase of the focus. If it be made, say, from a six to a nine inch the picture will be half as large again, and so on. It will be found that the quality of the image is little interfered with.

So far we have mainly referred to outdoor work, but the usefulness of the addition need not be restricted. We have been in studios where a picture has been brought to be copied to about half the size, or other similar proportion, for such purposes as placing in a locket. We have heard the remark, "Oh, what a nuisance! Our camera won't take it; it won't rack out far enough." Well, with anything like a suitable set of lenses and a good system of adapters or of loose fronts, the difficulty ought to be easily surmountable; but if no such plan can be adopted, it will be perfectly easy to do the work satisfactorily by the aid of a convex lens placed in front of the studio lens. A little fitting is all that is required, and there need be no trouble about that. We will on a future occasion give a few working details as to the use of supplementary lenses for the studio or enlarging room.

THE MANUFACTURE OF DRY PLATES.

[A paper read before the Croydon Camera Club.]

It is now fifty-four years since the first gelatine dry plate was made by Poitevin, who must be considered as the originator of the use of gelatine as a vehicle for the silver salts. Crude as his process naturally would be, it marked the beginning of a new era in photography, destined to revolutionise all the then existing methods and aspirations, and eventually to build up new trades and completely change the policy of other trades which originally had no connection with photography. Twenty-nine years later Dr. Maddox brought forward a gelatine emulsion process, which immediately put dry-plate making on a practical working basis, inasmuch as he disassociated his method from the existing wet-plate practice, which had cramped the utility of Poitevin's invention, and boldly emulsified the sensitive salts in the gelatine with which he coated his plates.

Two years later the first commercially made gelatine dry plates were placed on the market by Burgess. So much for the historical side of my subject. I have touched on it very briefly, its history is generally considered a dry subject; but I feel certain that could I ably tell you of the strivings and struggles of the pioneers, and the manner in which they literally fought their way to a knowledge of the laws of Nature affecting their particular calling, you would feel with me that the early history of dry-plate manufacture is full of romance and interest.

At the present time the dreams of the earlier experimentalists have been more than realised, and gelatine dry plate a hundred thousand times more sensitive than the earliest make are now in general commercial use, and it is about the manufacture of the present-day dry plate that I now wish to speak, and, with your permission I will take the different stages of manufacture as they appeal to me.

The factory devoted to dry-plate manufacture consists practically of five departments—the glass cleaning, the emulsion, the coating, the drying, and the packing departments—in all of which the strictest cleanliness and freedom from dust is demanded. Until comparatively recently all glass used for dry plates was of English manufacture. For a long time after

the quality of Belgian glass had reached the standard required; incorrectness of the cutting prohibited its use. The rectification of this very small but important matter was due primarily to an English manufacturer, who, feeling that he could set a superior glass, if once the correctness of cutting could be assured, went to Belgium and personally instructed the glass-maker how to overcome this trouble, and in the special requirements of dry-plate makers. To-day the glass of from twenty-five to thirty plates to the inch comes from France; the greatest portion of imported glass, that running from twelve to twenty-five to the inch, comes from Belgium; and it is only in glass of a heavier nature that the home market maintains its supremacy.

Of the agents used for cleaning the glass, which is now nearly entirely done by machinery, sod. carb. stands pre-eminent. The character of the matter to be removed sometimes varies, and to meet these variations, caustic soda, iodine and alcohol, whiting, tripoli, and alum are used, and if the substance is still obstinate, soaking for twenty-four hours in weak muriatic acid is resorted to. After being thoroughly cleansed the plate is dipped or flooded with a substratum bath, which is generally a mixture of chrome alum and gelatine, very weak, but sufficient when dry to give a better adhesive surface for the emulsion coating. The cleansed plates, having been thoroughly dried, are next taken to the coating room, wherein and henceforth all operations must be conducted in a properly screened light. The emulsion with which the plates will be now coated is a mixture of gelatine, iodide, and bromide of potass, silver nitrate, and ammonia. These components are all mixed together, care being taken that the brom. pot. is always in excess to prevent fog, and are digested for some hours at a temperature varying from 160 deg. to 190 deg. F., according to the season of the year and the kind of emulsion. When the digestion is finished—i.e., when by transmitted light it exhibits the correct colour which ranges from red to green, fresh gelatine is added and dissolved, after which the whole is frozen ready for the shredding which precedes the washing-out of the soluble salts formed during emulsifying.

The discovery of the necessity and advantages of this removal of the potassium nitrate salts was due to the researches of King in 1873. The emulsion, after washing, is again digested, and gains greatly increased sensitiveness thereby, and after an addition of spirit is ready for the coating machine. This machine consists chiefly of a train of bands which carry the glass plate under the coating weir, clean the backs, set the emulsion, and finally deliver the coated plates ready for stacking in the drying room, from whence, after a stay of about seven hours in a constant current of warm filtered air, they are removed to the packing department. The regulation of the amount to be delivered upon the surface of each plate is effected either by pumps, variations being obtained by altering either their number or their length of stroke; by scrapers, which scrape adhering emulsion from a glass roller revolving in a trough of emulsion, the regulation being effected by the width of the scraper; or by the simplest of all methods, the adaptation of the Marriott's bottle. There is still much room for improvement in the feeding and delivering apparatus at present employed, but this is only true if regarded from the economic side of the manufactory. Judging from the finished product no further improvement is necessary; the evenness of the coating exceeding the evenness of the surface of the glass. Before proceeding to the packing department the question of dark-room illumination may well claim our attention. With plates sufficiently sensitive to give well-exposed negatives with the exposure of one-thousandth part of a second in daylight, and with panchromatic plates sensitive to all but the deepest red, the coating, examining, and packing must be conducted practically in darkness. The method adopted to obtain the maximum luminosity with the minimum risk is known as the

"slit" method; this is simply an aperture about $1\frac{1}{2}$ in. by 6 in., so arranged with walls as to stand away from the lamp screen about 2 in. It may be imagined as a reversal of a focal-plane shutter, inasmuch as instead of the slit moving over the surface of the plate, the latter moves over the slit, and the brief exposure for examination does no harm.

The packing of plates is not interesting, being, after examination, simply a matter of careful handling and method; but the cutting machinery which reduces the size of the coated plates to quarters, halves, etc., is well worthy of attention as a triumph of ingenuity and finish. This machine, which is driven by a small motor, can be readily adjusted by the simple insertion of pegs to divide any required size, cuts easily thirty dozen whole plates to quarters per hour, entering each plate one thirty-second of an inch in, and leaving with the same margin, thus avoiding all chipping and consequent dust. The testing of the coated plate is conducted preliminary to packing. The tests are always made by the chief, the manager, or an assistant especially trained for the task. The faults looked for may be divided into three classes: Those due to the emulsion, the more prevalent coating defect, and those resulting from faulty drying. Those due to causes directly connected with the emulsion are most to be feared, inasmuch as they generally result in a day's work to be washed off.

Tests as to sensitiveness, density-giving power, and gradation are made with standards of light and exposure which vary together with their method of application in each works. Naturally, absolute correctness is totally out of the question; but, as in ordinary photography, such correctness is not needed, nobody is any the worse for the deficiency.

Some day in the far future, when if only optically plane glass is coated, it may be requisite to know the exact speed of a plate and its table of determined densities; but, until then, I feel sure that the clever researches which have recently been made in dry-plate sensitometry by our members, Messrs. Mees and Sheppard, will be chiefly useful in the laboratories of dry-plate factories, where I feel sure their works, together with the epoch-making discoveries of Messrs. Hurter and Driffield, will eventually be reckoned as assets of national value to us as the leading dry-plate manufacturing country of the world. In addition to the ordinary tests, orthochromatic plates are subjected to further tests for colour sensitiveness; these are mostly conducted by exposure through coloured mediums, by the spectroscope, and by camera trials on charts of colours. If the resulting prints are to be used for advertisement purposes, over-correction appears to be generally regarded as a necessary feature that the result may have a distinctive appearance.

Before closing my remarks I would like to mention a few interesting facts. Dry-plate, as well as wet-plate, photography, may be said to be primarily the result of French ideas, solidified and brought into working form by the slower-moving English brain. The home product of dry plates is far and away superior to the Continental makes, and this to me has always been an enigma. Practically every article used in the manufacture of dry plates is imported from Germany, yet in that country of profound thought and research there is not a plate factory of any magnitude. True, there are many small works; but, travel over the world as you will, or even go no further than the Continent of Europe, and you find English-made plates are preferred and used. This fact is keenly recognised by American makers and taken advantage of, as indicated by their purchase of English factories.

The question of prices and their possible reduction is bound to arise in the near future as the possibilities of over-production already loom in the distance. A great reduction must not be looked for, as the manufacture of dry plates has yet to free itself from many uncertainties, which, combined with the increasing cost of raw materials, diminish the possibility of a lessened price-list.

Nor do I think any great new departure in dry-plate manufacture is likely to occur. Like the bicycle, the dry plate is rapidly approaching a regular style, the prevailing indication being chiefly indicative of an extended use of the fastest ordinary and colour sensitive plates, and a neglect of slower plates even for purposes where their design makes them most efficient.

S. H. WRATTER.

DR. KOENIG'S COLOUR PROCESS.

SOME time ago a brief note as to Dr. Koenig's discovery of certain leuco bases of some organic dyes, which on exposure to light became oxidised to blue, red, and yellow dyes, appeared in the pages of the *BRITISH JOURNAL*; this obviously was a process outlined in the sensational paragraph which appeared in some of the daily papers last week, and the paragraph was founded on a lecture given by Dr. Koenig, at Breslau, at a meeting somewhat analogous to our British Association. The following note from the "*Deutsche Photographen Zeitung*" gives fuller details, and proves that the process is certainly full of promise.

Whilst the leuco bases of many classes of organic dyes, such as of safranine, for instance, are so prone to oxidation that they cannot be actually isolated in a free state, there are others, such as the leucomalachite green, which are, as is well known, easy to prepare in a pure state, and are approximately stable against atmospheric influences. It has recently happened to many chemists that these stable leuco bases, when kept for some time, become very strongly coloured when exposed to light. More accurate experiments as to the light sensitiveness of the leuco bases have, however, only been instituted by Gros in Ostwald's laboratory, and especially tested the leuco compounds of fluoresceine and its substitution products. He confirmed the fact that the leuco compounds, although prepared in a tolerably rough way, are almost all more or less sensitive to light, and measured the oxygen which would be absorbed by the aqueous solutions of the leuco bases or their salts in light.

Except for this no one appears to have entered at any length on such researches, and no one appears to have thought of using the leuco bases for obtaining photographic prints. Older, and up to the present used printing processes for trichromatic colour work, are well known. They are founded entirely on the light sensitiveness of gelatine mixed with bichromate. The least disadvantage of the old methods is the impossibility of seeing the progress of printing.

An ideal printing process for trichromatic photography must obviously be such as is neither stained nor printed on colour paper, a process which only works with colourless films, which, according to their preparation, give direct yellow, blue, or red prints.

In the search for such a printing process we in the laboratory of Meister Lucius and Brünig, of Höchst-am-Maine, experimenting with the various leuco bases, very soon had to recognise that the leuco bases, exposed by themselves alone to light, were not capable of giving sufficiently vigorous and brilliant prints. We then imbedded the leuco bases in a film of acetylhydrocellulose or gelatine. Our hope of obtaining more vigorous images was not, however, borne out.

Only when we used collodion as the vehicle did there suddenly show a quite unexpected advance in light sensitiveness. Leuco bases, which, exposed for hours by themselves to light and only showed a very faint coloration, were in the presence of collodion, even after a short exposure, fairly vigorously oxidised, and gave usable prints.

We very soon saw that the collodion could not act as a mere vehicle, and, as a matter of fact, it was seen that the leuco bases were oxidised in light at the expense of the nitric acid group of the nitrocellulose. We then tried a large number

other substances, and found that all the nitric acid esters, especially those of the higher alcohols, acted in the same way as nitrocellulose. The nitrous esters, on the other hand, and the isomeric nitrous bodies of the aliphatic and aromatic series, were inactive. The nitrosoamines showed a similar but somewhat weaker action than the nitric acid esters.

It is an interesting fact that the light sensitiveness of the mixture of nitrocellulose and leuco bases can be considerably lowered by the addition of urea and antipyrine. This observation appears to point to the fact that the leuco bodies were oxidised by the nitric oxide which has split off from the collodion. The addition of turpentine or anisol, which may be regarded upon as oxygen carriers, act, not at all, or to a scarcely noticeable degree, as accelerators in the formation of the light image. When we added various organic bases to the solution of the leuco substances in collodion, with the idea of preventing the small amount of oxidation by the air which many leuco bodies suffer, we were astonished to observe that films containing choline and its homologues were increased in light sensitiveness to an extraordinary degree. An explanation of this noteworthy phenomenon I am unable to give; there is probably some catalytic action.

Nitro-cellulose is not by any means the most active of the previously mentioned compounds; it is only specially suitable for the preparation of pictures, because it at the same time forms the film which carries the image. Much more sensitive will be the mixtures of the leuco bases with the nitric acid esters of glycerine, glucose, and mannite.

If a sheet of blotting-paper is soaked in an ethereal solution of, for instance, leucomalachite green or leuco flavaniline, it becomes coloured to a marked degree with a short exposure; to the solution, however, some nitro-mannite is added, the paper becomes intensely and very quickly coloured in the light. The light sensitiveness of the mixtures of the leuco bases and nitro-cellulose may be increased to an extraordinary degree by the addition of nitro-mannite, so much so that twenty seconds of sunshine is sufficient to produce a vigorous print.

It must again draw attention to the fact that it is quite impossible to produce even approximately useful photographic pictures with the leuco bases alone or with leuco bases suspended in an indifferent film. The prints are always flat and without vigour; the oxidation of the leuco bases in the light by the oxygen of the air appears to soon reach a maximum long before the whole quantity of the leuco base is oxidised.

By the use of various leuco bases, yellow, red, green, blue, violet, and grey pictures can be produced. The fixation of the pictures presented at first very great difficulties. Many of the leuco bases can be dissolved out of the collodion film by benzole, alcohol, ether, or chloroform; such fixing solutions are, however, not practical. The next fixing agents were dilute mineral acids, in which almost all the leuco bases very easily dissolve. In spite of this fact, however, the prints could not be thus fixed, because the leuco bases showed, like the dyes, a certain affinity to nitro-cellulose, and were sometimes very tenaciously held by the same. Fixation was better effected with diluted organic acids, and finally monochloroacetic acid proved to be the best fixing agent for almost all leuco bases. Acetic, di-, and trichloroacetic acid cannot be used.

Gros had already examined the behaviour of the leuco bases towards different coloured lights, and "in groben Zügen," as he says, determined that with most of the leuco bases there appeared a maximum of the coloration when they were exposed to a complementary light. Gros obtained with all leuco bases the weakest action under red glass, the strongest under "rosa" glass. We exposed the various sensitive films under light filters, such as are used for additive trichromatic photography; it was thus shown that the exposed strips showed a maximum action under the complementary filter, and a minimum action under the filter of the same colour. Thus, blue, green, and violet were coloured very strongly under red and yellow; under

blue they were scarcely coloured at all; whilst red was strongly coloured under the green and yellow filter, slightly under the blue, and not at all under the red. Finally, yellow was very strongly coloured under blue, and scarcely at all under yellow.

The strong action of the so-called "nonactinic" red on the blue and green light sensitive films is very interesting; probably the dye as it is formed acts as a sensitiser.

Ostwald has already remarked with regard to this that the actions of lights on photographic preparations are not peculiar to the light, that much more probably the light only accelerates actions, which, even with exclusion of light, would appear of themselves after a long time. As is well known, many photographic preparations become decomposed by long keeping in the dark, and especially quickly gelatine rendered light sensitive by bichromate. With our new light sensitive films the behaviour is just the same. The action which the light exerts in a few seconds or minutes appears in the dark after hours, days, or weeks, and actually the most sensitive films are the least permanent in the dark, so that they must always be prepared a short time before use. I will, therefore, remark that even with very long keeping in the dark the films are never so deeply coloured as in a short time in the light.

The application of these observations for trichromatic photography is as follows:—A sheet of paper is coated with the blue collodion and exposed to light under the corresponding negative. When the blue image appears sufficiently vigorous it is fixed in about a 10 per cent. solution of chloroacetic acid, washed, coated with a thin and hardened gelatine film, and dried. The gelatine film has the purpose of protecting the first collodion film from solution when the second is flowed over it. The dry blue image is then coated with the red collodion and placed under its corresponding negative, so that the outlines exactly correspond with the blue image. Another exposure to light is made, and the print fixed and washed, and finally, in a similar way, the yellow picture is produced. On account of the extremely thin films and the brilliancy of the colours used, the prints appear unique; the compound colours especially are rendered in an extremely satisfactory manner.

The quantity of the leuco bases used is so small, in consequence of the enormous richness of the triphenylmethane dyes, that a picture with the three composite films is scarcely more costly than an ordinary gum or carbon print. The stability of the pictures is naturally not absolute; even if relatively stable dyes are used for the preparation of the individual pictures. The least stable is the blue, which, however, surpasses that of the so-called blue print or cyanotype.

If one tots up the difficulties which are met with in the printing processes hitherto used in trichromatic photography, this new process of the Höchst Dye Works, which is called "Pinachromie," may be designated as an extraordinary advance. Coloured positives have, as is well known, been comparatively easy to prepare; but trichromatic photography could not, however, become popular so long as it was not possible to make paper prints in a simple way. This, we believe, our printing process permits even for the inexpert amateur, and it will, we hope, conduce to the end of reviving somewhat the waning interest in photography.

It is obvious from the above that, whilst the new process is certainly a noteworthy step, it hardly comes up to the glorious vision conjured up by the journalistic exuberance of the daily papers.

E. J. WALL, F.R.P.S.

At the last meeting of the Photographic Section of the G.E.R. Mechanics' Institution, Messrs. Elliott and Sons' loan lecture on "Majorca," was read, in the unavoidable absence of the instructor, Mr. Bennett, F.R.P.S. The lecture was much appreciated, and the varied colours of the slides, which are all upon "Barnet" plates, was very favourably commented upon.

A PRESS SIDE-LINE.

By A LONDON JOURNALIST.

PROFESSIONAL photography means portraiture, and it will continue to mean so to more than ninety per cent. of those who make a living with their cameras. But while portraiture is the greatest standby to the photographer, it is by no means the only one. Many a wide-awake man changes a bare living into a comfortable one by taking up some special line. I met a man recently who told me that he was increasing his income more than fifty per cent. by picture post-cards. If I had been in his place I should have smiled at the "craze" and despised it. But he was wiser; he saw his opportunity and took it. All the wealthy people of the village—and they were numerous—were wont to be photographed in fashionable West End studios, and never visited the man whose largest camera was whole-plate. But when he offered them picture post-cards at three shillings a dozen they bought largely. The post-cards were of their own houses, their gardens, their gate-lodges, or their live stock. By offering such a number of subjects the orders were satisfactorily large. By these post-cards a great deal of erstwhile "spare" time was made to earn good wage—and something over. Probably many photographers could not make a success with post-cards; conditions vary. There is no one line which may be universally adopted by those "desiring to increase their income"; but there are many lines which prove paying ones in some places.

But I did not start this article to preach about side lines for portrait photographers; that will keep for another time. But just as the portraitists may make a smaller or greater percentage of money outside the usual groove, so does a certain percentage of the profession break away entirely from the ordinary studio work, and makes money in other lines.

It has been said that the profession is recruited from amateur ranks. I know very little about it, and so perhaps am rather dogmatic in my opinion—but I certainly do not believe it. But I do know several cases where amateurs have drifted into commercial work where the bright son of a professional worker might just as well have had the chance—if he had only seized the opportunity.

The special side-line I have in mind is connected with Press photography. I am not going to advise anyone to rush into that much-belauded and little-understood business, the supplying of topical pictures to the weekly papers at half a guinea a time. There is money in it for a few, and the field is well filled. But several papers know that they want a man who will do special commercial work for them—and other papers that do not know it will do so when the right man explains the situation to them. I know the papers want the man, for within the last six months I have myself had two offers from editors of feminine fashion papers who would rather illustrate with photographs than with sketches. The American papers have shown them the way. I went into the matter with one editress, and she explained what she wanted. There are, say, a dozen new fabrics for autumn wear. To make a sketch of a fabric which will tell a woman what it really is would be a heavy task for an artist. He can show the design of a piece of lace, but can do little more—that is, at a price. But a photographer who knew his camera could make a negative of those fabrics which would be wonderfully like the original material. The lace, too, or embroidery, would be like the thing itself, instead of a mere plan design. These same papers are full of articles on the coiffure, fancy stitches, manicuring, how to set a table, how to arrange flowers, and half a hundred similar subjects. If a woman is interested in coiffure she will get that paper which, in a series of half a dozen photographs, shows clearly every detail of the procedure. A page showing nine photographs of girls, each crowned with a "latest creation" in hats, would attract more interest than a page of sketches. And some of the editors, who find a full hundred explanatory

photographs in some American magazines, are awake to advantage; and as they lead others will follow.

It may be that the work—at least, the exposure—will be in many places, much of it at editorial headquarters, much of it at various millinery shops. Perhaps the photographer be required to find his own models—a dozen "hat" pictures would mean a dozen different pretty faces. More probably they will be procurable among the many girl employees of a fashion magazine, or from the shop-girls at the milliner's, will not be straightforward work at first. The editress knows what she wants, and it will be the photographer's part to know how to do it. It will need to be very good technical work and yet it will often have to be put through quickly. The photographer will need to have his wits about him.

I have spoken about feminine magazines, for there are openings undoubtedly in other papers have similar openings in a smaller degree—when they find the right man. He is not easy to find; but if he turns up he will find, just at present, there is room for him.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE PROFESSIONAL SECTION.

THE professional section at the present Exhibition at the New Gallery is far short of what it should be, and it is a surprise that those engaged in the business of photography should be content to let slide the opportunity which the Society offers for the exhibition of their work. As it is, the room is devoted almost entirely to a display of the products of paper and material men, who, while providing in some cases an excellent show, were contemplated when this section was first provided. The result is a very mixed affair, and some of the panels and exhibits are not in the best of taste.

Mr. William Crooke, of Edinburgh, has two large portraits—of Miss Kate Douglas Wiggin—which are similar in character to those by the same author hung in the West Room, Pictorial Section. As Mr. Crooke has already pointed out, it should not be forgotten that these pictures are not specially prepared exhibition works but such as Mr. Crooke turns out in the ordinary way of business. Both are fine pieces of work and worthy of their producer.

A small case of water-colour miniatures on ivory by Mrs. Turner, shown by Mr. T. C. Turner, of Hull and London, though photographic, points to a class of business which may well be taken up by the professional man who sees an opening for new things. Mrs. Turner has exhibited her miniatures at the Royal Academy and other shows, and a comparison of these excellent examples of straightaway painting without a photographic basis (done in the ordinary course of business), with the tinted photographs usually shown as miniatures, will be interesting to the visitor.

New exhibitors in this section are Messrs. Alfred Ellis and Walter of Baker Street, who, on a panel about 18ft. long, show a score of photographs, large and small, which, besides being interesting, account of the well-known personalities portrayed are of a high order of merit. The subjects are mostly theatrical, and the exhibit attracts a good deal of attention.

Kodak, Ltd., follow with an exhibit contained in a large oak frame filling some 21ft. of the West wall, which consists of a number of enlargements from Kodak negatives on various kinds of the common bromide papers. There are several military photographs, four by Dr. Vaughan Cornish showing the wane phenomena of Niagara, and as showing what can be done with cheap apparatus, four photographs taken with a "Brownie" camera attached to a microscope. The general arrangement of the panel is in the usual good taste displayed by the company's exhibits.

We next come to a small collection of photographs by Mr. Fellows, which reflect in an admirable manner the qualities peculiar to the bulk of his work. There is an old friend or two which he has gained commendation many times before and some new work which well maintains its author's reputation.

Immediately following this group, and in the same panel, is a display of framed prints on "Helion" paper, a printing-out paper with a matt surface giving pictures resembling very closely those on carbon and platinum papers. The prints may be toned with platinum

or gold, preferably both, and the colours obtainable cover a long range, brown, red, violet, engraving black, etc.

The Autotype Company's exhibit occupies the whole of the end wall as usual, and in general arrangement is not noticeably different from that of immediately preceding years. The effect is improved by the absence of the violent contrasts due to the display of pictures on carbon tissue of conflicting colours, and the company is to be commended for the good appearance of the wall. The exhibits consist of carbon reproductions of well-known pictures in oil and water-colour by prominent painters, together with carbon enlargements in a variety of colours from negatives by some of the foremost photographers. The collection of prints, which are tastefully framed, make a very attractive exhibit.

From these pictures we turn to the next panel, which is filled with examples of the application of "Photolinol," a new production for the results upon which absolute permanence is claimed by Photolinol, Ltd., the makers of the material. Photolinol is a bromide linen, and the pictures, which are chiefly enlargements of extensive proportions, show that the fabric can be used as a base for painting upon without preparation, and for photographic pictures to be subsequently finished in black and white, etc. Several of the pictures are shown as transparencies here and in other parts of the gallery. The exhibit includes also some pictures on printing-out linen and on opal.

Messrs. Thomas Illingworth and Co., Ltd., devote a considerable space to a display of big enlargements in various colours, which serve as examples of their carbon tissues. The sepia bromide enlargement of the Marquis of Anglesey in costume can scarcely claim to be considered from the photographic point of view so extensive and obvious is the subsequent hand-work of the artist. The other subjects are from negatives by well known photographers, and they show what effects different papers and pigments can be made to yield. The framing of the exhibits has also been executed by the firm, who make a special feature of this class of work.

Of the exhibits shown by Mesdames Garstin and Antrobus of the Cavendish Studio, there is not much to be said. Some of the prints are in good style and creditable as everyday productions, but others seem to be hardly worthy of exhibition. The exhibits are all small and the subjects are in several instances well known public men and women.

The Gem Dry Plate Co., Ltd., have on view a large frame containing enlargements on "Gem" bromide paper from negatives on "Gem" motor plates. There is nothing very special about the exhibit, which is the last in the room.

As a conclusion to this notice we would again refer to the matter touched upon at its commencement, and urge professional photographers to be more alive to their interests. The exhibition is visited by many thousands of people, of whom a large proportion are members of the great British public not particularly interested in photography except so far as its results are concerned. Surely it must be worth while to bid for their patronage on the very reasonable terms which the Society offers. We hope next year to see the profession assert itself, and, with all respect to the manufacturers, for whom the Fountain Court is provided, see that nothing but purely professional photography occupies the walls of the North Room.

THE HOVE EXHIBITION.—The prospectus and entry form of the ninth annual exhibition of the Hove Camera Club has been sent us. Five open classes are announced, and the awards take the shape of handsome bronze plaques of a novel shape and design. They will measure 7½ and 4½, and thirteen of them will be placed at the disposal of the judges, Messrs. E. R. Ashton, A. Horsley Hinton, and C. Job. The Club classes have not been neglected, and numerous awards are offered to competing members. In addition to these awards a plaque ("L'Angelus," by G. Dupré) will be awarded jointly by the Hove, Southsea, and Southampton Societies to the exhibitor at all three exhibitions, whose work shall be judged to be of the highest merit. These three flourishing societies have quite taken the lead in all exhibition matters in the South of England during the past few years, and there is every indication of their continuing to do so this season. November 16 is the latest date for entries for the Hove Exhibition, and pictures entered at the Southsea and Southampton shows will be forwarded free of charge from Hove to Southsea and from Southsea to Southampton. Full particulars and entry forms can be obtained from the Hon. Sec., A. R. Sargeant, 55, The Drive, Hove.

Exhibitions.

ASHFORD PHOTOGRAPHIC SOCIETY.

The first annual exhibition of the Ashford (Middlesex) Photographic Society was held on Thursday last week, and can be written down as an unqualified success. This to a great extent was due to the work of the indefatigable hon. secretary, Mr. G. K. Rule, who has devoted a deal of time to the Society. The other officers are:—Hon. treasurer, Miss E. G. Cook; committee, Miss White, Miss Sales, Mrs. Oakeshott, Messrs. Buckle, Bunnett Crosby, Higgins, Neaves, Hill, and the Rev. G. J. M. Kingston. The exhibits numbered about 400. The judges were Messrs. Henry Stevens, Thomas Bedding, F.R.P.S., and S. T. Bates.

Open Section.—Medal: Mr. H. Robinson's "The Hon. Sec."; highly commended, Mr. F. W. Bartlett's "The Day is Dying in the West"; highly commended, Mr. G. K. Rule's "Homewards."

Architecture.—Medal: Mr. F. W. Bartlett's "Entrance to Priory Church, Bridlington."

Landscape.—Two Medals: Mr. H. P. Higgins' "And Frae the Yellow Field"; highly commended, Mr. H. P. Higgins' "Where Flocks Increasing."

Portraiture.—Medal: Mr. H. P. Higgins' "A Night of the Road"; highly commended, Mr. H. P. Higgins' "Two English Roses."

Still Life.—Highly commended: Mr. G. K. Rule's "Lily."

Architecture.—Medal: Mr. F. W. Buckle's "Lincoln Cathedral (nave)"; highly commended Mr. G. K. Rule's "Roman Arches"; highly commended, Mr. G. K. Rule's "To the Glory of God, Norwich."

FORTHCOMING EXHIBITIONS.

October 15-29.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.

October 18, 19, 20.—Kettering Church Institute Photographic Exhibition. Hon. Secretary, E. Claypole, 112, Hawthorn Road, Kettering.

October 19-20.—Isle of Wight Photographic Society. Hon. Sec., J. Howard Burgess, 53, Pyle Street, Newport, I.W.

October 19-22.—Rotherham Photographic Society. Hon. Sec., H. C. Hemmingway, Tooker Road, Rotherham.

October 25-28.—Watford Camera Club. Hon. Sec., H. G. Trayfoot, 3, The Parade, Watford.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Barnbygate House, Newark.

November 2-25.—Plymouth. Hon. Sec. Photographic Section, Chas. B. Rowe, 2, Walnut Villas, Cockington, Torquay.

November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 15-19.—Sunderland Camera Club. Hon. Sec., Selby Ord, 52, Frederick Street, Sunderland.

November 17-18.—Braintree and Bocking Camera Club. Hon. Sec., W. H. Tilston, 81, High Street, Braintree, Essex.

November 17-19.—Darwen Photographic Association. Hon. Sec., J. G. Thomas.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.

November 23-25.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarnock Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.
 December 23-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 133, Glasgow Road, Wishaw.
 January 12-14, 1905. Boston Camera Club. Hon. Sec., H. M. Hames, 65, West Street, Boston.
 January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.
 January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.
 January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.
 February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.
 February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.
 March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.
 June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.
 October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.
 November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.
 December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.
 March 15, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

THE SCOTTISH PHOTOGRAPHIC FEDERATION, SEASON 1904-1905.

The following is the list of judges for exhibitions and competitions, lecturers, demonstrators, lectures for circulation, and lantern slides for circulation.

JUDGES.

The following gentlemen have kindly agreed to act as judges to federated societies for their exhibitions and competitions. Arrangements must be made with the judges direct, as circumstances might prevent them officiating on the occasion required. All expenses must be paid by the society requesting their services:—

For Prints.—Godfrey Bingley, Esq., Thorniehurst, Shaw Lane, Headingly, Leeds; Arch. Campbell, Esq., Stewart Terrace, Barnhill, Broughty Ferry; Ezra Clough, Esq., Faircliff Road, Bradford; Arch. Cochrane, Esq., Barrhead; W. Crooke, Esq., 103, Princes Street, Edinburgh; J. W. Eadie, Esq., Lenidale, Airdrie; A. Keighley, Esq., Steeton High Hall, Keighley, Yorks.; Frank P. Moffat, Esq., 125, Princes Street, Edinburgh; James Patrick, Esq., 11, Bruntsfield Place, Edinburgh; and J. Douglas Ritchie, Esq., 5, Gilmour Street, Paisley.

For Lantern Slides.—Vaness C. Baird, Esq., Broughty Ferry; Godfrey Bingley, Esq., Thorniehurst, Shaw Lane, Headingly, Leeds; Arch. Campbell, Esq., Stewart Terrace, Barnhill, Broughty Ferry; J. W. Eadie, Esq., Lenidale, Airdrie; Wm. Ellison, Esq., 2, Balhousie Street, Perth; Frank P. Moffat, Esq., 125, Princes Street, Edinburgh; James Patrick, Esq., 11, Bruntsfield Place, Edinburgh; J. Douglas Ritchie, Esq., 5, Gilmour Street, Paisley; T. W. Robertson, Esq., 5, Whitehill Gardens, Dennistoun, Glasgow.

LECTURERS.

Alex. Adam, Douglas Terrace, Stirling: "A Trip to Italy," illustrated by slides. Arch. Campbell, Stewart Terrace, Barnhill, Broughty Ferry: "The Reproduction of a Photograph," being a description of the various methods of newspaper and book illustration, illustrated by examples. Henry Coates, Pitcullen House, Perth: "Snapshots in the Rocky Mountains," illustrated by slides: "A Yachting Cruise Among the Northern Isles," illustrated by slides. M. B. Craig, Kirk Brae, Wishaw: "Coal Mining in Lanarkshire," illustrated by over 100 slides. W. S. Crocket, 72,

Main Street, Tollcross, Glasgow: "Hand-Camera Photography," illustrated by about 24 slides. Rev. John Crouch, Bridge of Weir: "Through North and North-Eastern France with a Camera"; "The Engadine and the Italian Lakes" (lantern slides for above two lectures by T. H. Taylor, L.D.S. J. W. Eadie, Lenidale, Airdrie: "Mounts and Mounting," illustrated by prints and samples; "Composition," illustrated by diagrams; "Pictorial Record (official of the Glasgow Exhibition)," illustrated by 200 slides; "Behind the Scenes at the Camera at the Wild West," illustrated by 120 slides. W. D. M. Falconer, James Street, Blairgowrie: "Photographic Optics for Beginners," illustrated by diagrams, blackboard and coloured chalk required. Peter Henderson, M.A., B.Sc., 5, Wortley Place, Dundee: "Orthochromatic Photography," lantern required. A. W. Hill, Commercial Bank of Scotland, Shotts: "Gum-Bichromate Printing," illustrated by specimens from Miss Warburg, Messrs. J. Page Croft, James Gale, J. M. C. Grove, and other leading exponents of this process. W. B. Hossack, Deveron Bank, Airdrie: "Stereo-Photography," illustrated by specimens, prints, and apparatus; "A Trip to Holland," illustrated by 150 slides. G. Jack, Wellington Street, Airdrie: "In and Around Glasgow Cathedral," illustrated by 75 slides. T. A. Macfarlane, Jacksonville, Airdrie: "A Trip to Egypt," illustrated by 75 slides. John B. MacLachlan, Blairgowrie: "From Castle to Palace" (Old Edinburgh), illustrated by 50 slides. "Photography with a Purpose"—an advocacy of specialisation; "Union is Strength"—a plea for combination. J. Wilson Paterson, Victoria Place, Airdrie: "A Tour through Norway," illustrated by 120 slides; "Switzerland and the Rhine Valley," illustrated by 150 slides. S. Stewart, F.I.C., 2, Salisbury Street, Kirkcaldy: "A Week in Holland with the Hand-Camera," illustrated by 100 slides. D. Storrar, 223, High Street, Kirkcaldy: "Art in Relation to Photography," illustrated by slides. A. A. Symon, M.A., B.Sc., May Terrace, Wishaw: "Herring Fishing on the Moray Firth," illustrated by 80 slides. J. M. Thomson, F.S.M.C., D.B.O.A., 47, High Street, Dundee: "Elementary Photographic Optics," lantern required. E. D. Wilmot, University Union, Edinburgh: "Fifty Miles Round Edinburgh," illustrated by 75 to 100 slides.

DEMONSTRATORS.

Vaness C. Baird, Broughty Ferry: "Carbon"; 1/1 dishes, hot and cold water required. George L. A. Blair, 49, High Street, Paisley: "Gum-Bichromate Printing," "Carbon," and "Platinotype." J. W. Eadie, Lenidale, Airdrie: "Platinotype" and "Carbon." A. W. Hill, Commercial Bank of Scotland, Shotts: "Gum-Bichromate Printing." Thomas Lupton, Abercromby Place, Stirling: "Lantern Slide Making." G. D. Macdougald, F.I.C., Shore Terrace, Dundee: "Gum-Bichromate Printing." J. Wilson Paterson, Victoria Place, Airdrie: "Lantern Slide Making."

LECTURES FOR CIRCULATION.

Vaness C. Baird, Broughty Ferry: "Short Notes on a Tour in Normandy," illustrated by 60 slides. A. A. Chisholm, Lochmaddy: "The Outer Hebrides" (lecturette), illustrated by 30 to 40 slides. W. D. M. Falconer, James Street, Blairgowrie: "Photographic Optics for Beginners," illustrated by diagrams. A. W. Hill, Commercial Bank of Scotland, Shotts: "Gum-Bichromate Printing," illustrated by specimens by leading workers. Alexander Hinshelwood, Coltness Farm, Wishaw: "A Tour in the Engadine, Eastern Switzerland"; "A Tour Through Part of France, Italy, Switzerland, and Germany"; "A Tour in Grand Canary"; "A Tour in Scotland"; "A Tour in Geneva, Chamounix, and Zermatt"; each lecture illustrated by about 50 slides.

LANTERN SLIDES FOR CIRCULATION.

Alexander Adams, Douglas Terrace, Stirling: "A Trip on the French Riviera" and "A Tour Through Norway." Vaness C. Baird, Broughty Ferry: "Norway," 80 slides. Hans Gaertner, Dundee (on application to Vaness C. Baird, Broughty Ferry): "Walks Abroad," about 70 slides. Thomas Lupton, Abercromby Place, Stirling: "A Tour Through 'The Raiders' Country" and "A Trip to St. Kilda." W. C. Shaw, 18, Forth Street, Stirling: "Robert Burns."

Mr. R. J. Moss, of 98, Snow Hill, Birmingham, the well-known maker of acetylene generators, informs us that he has appointed Mr. E. G. Wood, of 2, Queen Street, Cheapside, to be his London agent.

New Apparatus, &c.

The "Merito" Negative Drying Rack and the "Merito" Printing Frame. Sold by W. L. Parkinson, Ltd., 62, Dale Street, Liverpool.

The "Merito" Negative Drying Rack can claim novelty, simplicity, and effectiveness as its chief merits, and its usefulness is at once apparent. There are few photographers, whether professional or amateur, who have not experienced difficulty in trying to dry plates of flat films in the ordinary rack for holding negatives, owing to the principle being wrong for lack of air space, and

particularly the bottom portion, a long time to dry. The "Merito" rack overcomes this difficulty in a simple and efficient manner, the plates draining with the whole of the film surface exposed to the air to play all over. A perforated V groove carries the water away from the bottom edge of the negatives, and as no water can lodge, the bottom portion dries almost as soon as any part of the negative, saving a considerable amount of time. This feature will appeal to all photographers. The rack is arranged to carry twelve $\frac{1}{4}$ -plates, or eight $\frac{1}{2}$ -plates or any size plates up to 4 by 10. It can be folded flat for storing away when not in use.

The "Merito" Printing Frame possesses many advantages for contact photography, amongst which its simplicity is prominent, there being nothing to arrange or set. The negative is placed in the recessed opening provided in the centre of the frame, and the print is placed in any position desired, which may be lengthwise, crosswise, any way or angle considered best to print. A brass wire is fixed on the edge of the frame back, projecting sufficiently

on the underside to fit any of the four corresponding grooves which go round the outer edge of the frame, thus preventing the back, and consequently the card or print, from moving when being examined. Portions of the negative may be printed, and to photographers who know the value of this, full advantage can be taken in an effective manner, with this frame. In addition, should the lines on the negative be out of perpendicular, sufficient space is available on the frame bed to adjust the print.

Griffin "Bromide Paper." Made by Messrs. J. J. Griffin and Sons, Ltd., 20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.

This new bromide paper, which will be known in future as "A-1 grade snow-white," is the latest product of this firm, and prints on it possess great richness in the blacks and purity in the high lights. For enlarging it is specially suitable, having a rapid emulsion, thus making it possible to secure fully exposed enlargements by reasonably short exposures. There is no tendency to fog or greyness. The exposure necessary to secure a fully exposed contact print will be found surprisingly short, and development is very easy. To develop the image, first soak the paper in cold water in a clean porcelain dish. Pour the water off after it has been immersed 15 seconds, and apply evenly either of the following developers:—Amidol: Amidol 70 gr., sodium sulphite, cryst. 650 gr., potassium bromide 15 gr., water 20 fl. oz.—or—Metol-Quinol: Metol 8 gr., hydroquinone 30 gr., sodium sulphite, cryst. 240 gr., sodium carbonate, cryst. 360 gr., bromide of potassium 4 gr., water 25 oz. If the whites of the print are greyish, or the shadows lack richness, increase the amount of bromide of potassium. After development, rinse print in water and fix in soda hyposulphite 1 oz., water 10 oz., for ten minutes. Then wash for half-an-hour in running water.

Messrs. Griffin wish to draw attention to the fact that they are putting up this paper in the larger sizes in packets of four pieces only. They believe this will prove of great convenience to those making only occasional enlargements. "A-1 grade" is very suitable for toning with the sulphide bath, very fine sepias being obtained. The following toning baths may be used for producing sepia and blue prints, but they are not necessarily permanent:—Toning bath for sepia prints: Potassium citrate, 10 per cent. solution, 1 oz.; copper sulphate, 10 per cent. solution, 70 minims; potassium ferri-cyanide, 10 per cent. solution, 60 minims. Toning bath for blue prints: Ammonia citrate of iron, 10 per cent. solution, 2 drms.; potassium ferri-cyanide, 10 per cent. solution, 2 drms.; water, 40 drms.

Zigo. Made by Thomas Illingworth and Co., Ltd., Willesden Junction, London, N.W.

Zigo is a new self-toning paper recently introduced by the firm of Illingworth. They claim for this paper that it has a distinct advantage over any other self-toning paper, inasmuch as it gives tones ranging from red to purple without any chemicals whatever other than hypo. Zigo is, of course, a P.O.P., and is supplied with either matt or glossy surface. The tones obtained by simply placing the print in a solution of hypo are very satisfactory. The points to remember when using this paper are: The prints must be printed a little darker than the finished print is required, as they reduce somewhat in fixing. They look a rather redder tone when wet than when dry; allowance, therefore, must be made for this when taking out of the hypo solution. Zigo matt prints are generally preferred in the red tone. They take a little longer to tone than the glossy, and should be printed a little lighter and left in the hypo solution a little longer than the times given for glossy prints, or the hypo solution may be strengthened. Zigo postcards curl a little after drying, and these can be easily flattened by drawing the card sharply under a piece of wood having a smooth, sharp edge. To tone:—Remove the print from the printing frame, and place direct into the following bath. Hyposulphite of soda (hypo), 3 oz. (3 tablespoonsful); water, 20 oz. (1 pint). It is advisable to mix the hypo in a little warm water, and then make up to the pint with cold water. For red tones allow print to remain six minutes; for brown tones, ten minutes; for purple tones, fifteen minutes. If a deeper tone is desired add more hypo. When the desired colour is obtained, place the print in running water, or constantly change the water for half an hour, and the operations are then complete.

Patent News.

The following applications for patents were made between September 19 and October 1, 1904:—

Storing Negatives.—No. 20,114.—“An improved system for storing photographic negatives.” (Houghtons, Ltd., and Alfred Sydney Spratt.)

Paper.—No. 20,157. “Improvements relating to paper and other surfaces for photographic printing.” (Jean Baptiste Germeuil Bonnaud.)

Cameras.—No. 20,269. “Improvements in or relating to photographic cameras.” (Edward Sanger Shepherd.)

Shutters.—No. 29,237. “Improvements in shutters for photographic cameras.” (The Thornton-Pickard Manufacturing Company, Ltd.)

Pneumatic Balls.—No. 20,330. “Improvements in pneumatic balls for photographic shutters and apparatus for compressing same.” (The Thornton-Pickard Manufacturing Company, Ltd.)

Cameras.—No. 20,384. “Improvements in photographic cameras.” (George Washington.)

Drying Line.—No. 20,414. “A portable drying line for film negatives and photographic prints.” (William Johnston.)

Cinematographs.—No. 20,429. “Improvements in mechanism employed in the production of cinematograph and mutoscopic pictures and dark slide for carrying sensitive photographic plates for taking impressions.” (Henry William Hamblin Palmer.)

Cinematographs.—No. 20,430. “Improvements in mechanism employed in the production of a series of photographic cinematograph pictures animated, also mutoscopic and stereoscopic to be actuated by coin-freed mechanism and circular dark slide for holding sensitive plate or disc.” (Henry William Hamblin Palmer.)

Printing Apparatus.—No. 20,507. “Photographic printing apparatus.” (Herman George Schumann.)

Dark Slides.—No. 20,556. “Improvements in photographic dark slides or plate holders.” (Arthur Lewis Adams.)

Cameras.—No. 20,634. “Improvements in photographic cameras.” (Alfred William Bevis.)

Temporary Support.—No. 20,726. “A temporary support for sensitive photographic emulsions.” (Henry James Burton.)

Cameras.—No. 20,729. “Improvements in photographic cameras.” (The Thornton-Pickard Manufacturing Company, Ltd.)

Apparatus.—No. 20,769. “Improvements relating to photographic apparatus.” (Benjamin Joseph Edwards.)

Plate Carriers.—No. 20,827. “Improvements in carriers for sensitised plates used in colour photography.” (Benjamin Jumeaux.)

Developing Dishes.—No. 20,933. “Improvements in developing, rinsing, and fixing dishes and developing and fixing tanks for photographic purposes.” (James Everett.)

Films and Filters.—No. 20,954. “Improvements in or relating to the arrangement of films and filters for three-colour photography.” (Hans Schmidt.)

Computing Exposures.—No. 21,080. “An instrument for computing photographic exposures.” (John Walker Newall.)

Cameras.—No. 21,133. “Improvements in or relating to cameras.” (Alfred Herbst.)

MRS. ISABELLA L. BISHOP, better known as Miss Isabella Bird, the famous traveller and authoress, died in Edinburgh on Friday, within a few days of completing her seventy-second year. Her first book, “The Englishwoman in America,” was published so long ago as 1856, and so recently as 1900 she published “The Yangtze Valley and Beyond.” Mrs. Bishop was an ardent supporter of philanthropic work at home and abroad, and had built five hospitals and an orphanage in the East. She married, in 1881, Dr. John Bishop, who died in 1886. In 1901 she rode a thousand miles in Morocco, including a journey to the Atlas Mountains. She was a Fellow of the Royal Geographical Society (the first lady Fellow elected to that body), a member of the Royal Photographic Society, and an honorary member of the Oriental Society of Pekin.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION— LIVERPOOL BRANCH.

THE first monthly meeting of the season was held at the Alexandra Hotel, Dale Street, on September 28th. Mr. Mowll occupied the chair. The question of inviting the local photographers to a meeting with the object of discussing prices, was brought forward, and after some argument it was unanimously decided that such a meeting be held on November 4th. It was hoped that many members of the profession would attend, and that the opinions expressed might make possible some measures tending to reduce the extreme price cutting in the city and district. The chairman suggested that at the same time the idea of forming a professional photographers' club might be laid before the photographers of the district and opinion invited. Such an institution would certainly be useful to members of the profession, and could be promoted easily and with a moderate outlay, if photographers would give it anything like united support. One saw the same faces, time after time, at these meetings, and it was hard to believe that of all the photographers in Liverpool they were alone anxious to attempt something for the benefit of the profession, to help each other. The formation of a club would bring them together, and most might learn something to their advantage from the experiences of others. The hon. secretary was instructed to send a copy of the following circular to each professional photographer in the district: “The Liverpool branch of the Professional Photographers' Association beg to invite you to a discussion relative to professional photographers' prices in the district, and with regard to forming a professional photographers' club, on November 4th, 1904, at the Alexandra Hotel, Dale Street; chair to be taken at 8 p.m.

CROYDON CAMERA CLUB.

OCTOBER 5.—The first meeting of the winter session was held in the club's new premises, No. 128a, George Street, which are in every way an improvement on the rooms vacated. More commodious, tastefully decorated, better ventilated, and with a capital enlarging and dark rooms annexed, it was small wonder that a general and unanimous feeling of satisfaction at the change prevailed. This was voiced

by the President, Mr. S. H. Wratten, who, in welcoming the members to their new abode, expressed his thanks to the small band of energetic and willing workers who had so successfully carried the matter through. A cheery note was also sounded by the Hon. Sec., Mr. H. M. Bennett. A large number of new members had joined, and he thought the club in the healthiest possible condition. It was also well represented at the Royal Photographic Society's Exhibition and the Salon, and Mr. C. Austin was to be congratulated on having obtained a medal at the former. Other speakers followed in the same appreciative strain.

The President then read a short but most interesting paper on the manufacture of dry plates, the full text of which will be found in another column. Samples of the gelatine employed, dried emulsion, and coated but undried plates were passed round and examined with interest. In respect of the latter Mr. Wratten showed how the momentary application of a warm finger to the glass side of a plate had resulted in a permanent marking on the sensitive surface. A warm-handed assistant, he said, was not of much use in a dry plate manufactory. In answer to questions, he stated he believed gelatine improved by keeping, and he invariably stored it for a considerable time before use. Makers, however, had different ideas on storing and blending gelatine, but in any case it was of the utmost importance that it should be perfectly pure. The excess of bromide in an emulsion was removed by washing, but an after addition of the restrainer was desirable. A very fast plate would not be successfully made without it.

In the short discussion which followed Mr. C. E. Kenneth Mees said, when testing commercial plates he could generally find if free bromide had been added. It had a somewhat remarkable effect upon "speed." In one particular case on starting development the speed indicated 150 Watkins. On pushing development to infinity, the speed was found to reach 1,000 Watkins. Messrs. Wratten and Wainwright's plates did not exhibit such eccentricities. After a few appreciative and retrospective remarks from Mr. Packham, a most hearty vote of thanks was accorded the President.

BOWES PARK AND DISTRICT PHOTOGRAPHIC SOCIETY.

OCTOBER 8th.—Mr. A. H. Lisett delivered a lecture on "Home Portraiture, Indoors." The lecture was illustrated by over fifty lantern slides, to indicate the work which could be done in an ordinary room. The value in the use of screens and background, combined with modified lighting from the window, was very clearly shown, slides being exhibited giving diagrams of position of camera screens, sitter, and background, also the window, the light from which had been considerably restricted, in order to obtain different effects. Also results were shown of photographs taken of a subject sitting in a window, through which the full glare of sunshine was falling. These slides were most remarkable, no trace of halation being visible. Mr. Lisett recommended the use of as long a focus lens, as the room used would permit, also that before taking up the work a study should be made of paintings of the leading artists, especially those of the Dutch artists. It would be found, Mr. Lisett said, that simplicity in pose and surroundings would give the most artistic and therefore pleasing results, and this, he contends, should be the aim of all who would endeavour to do the most successful work. Mr. Lisett stated he had found the Watkins' method of time development most useful, and he now invariably used it. By this means he was able to get the results he desired with greater certainty, and he therefore recommended it.

We are informed that the Gateshead Camera Club has been reorganised, and arrangements for the coming winter season are now complete. The club rooms, at 87, High Street, Gateshead, have been newly decorated and furnished for club purposes. The dark room is fitted with sink, benches, a water supply, and other necessities. A first-class half-plate enlarging lantern has been purchased, and is now fixed, ready for the use of members. Arrangements are being completed for elementary photographic classes, to be conducted by members of the club, on Monday evenings, commencing on the 17th inst. The syllabus followed will be that of the City and Guilds of London Institute. Particulars may be obtained from the club secretaries. A few non-members will be admitted to these classes. Lectures of an advanced and miscellaneous character are being arranged for the Thursday evenings.

News and Notes.

THE Photographic Club has removed its headquarters and meeting place to Huggett's Red Cross Hotel, 19, Paternoster Square, E.C.

THE Thornton-Pickard Manufacturing Company's competition is now closed, and we shall shortly publish the results of the judging.

THE final date for receiving entries to the Watford Exhibition has been extended twelve days, and is therefore October 17. The date for receiving the exhibits is, as before, October 19.

THE Wimbledon Camera Club opened their winter session and new headquarters at Rembrandt Studios, Hill Road, Wimbledon, on September 30, with a practical demonstration on "Platinotype Printing for Beginners," by Mr. E. T. Holding.

WE regret to have to record the death of Mr. R. K. R. Flamank, of the firm of R. Flamank and Son, Sutton Street, Aston, Birmingham. Mrs. Flamank will continue to carry on this well-known business, which will, as hitherto, be conducted on prompt and businesslike lines.

THE prospectus of the Hartlepool Fourth Annual Exhibition has been sent us. It is noteworthy that the exhibition is divided into two sections: (1) Photographic, and (2) Art. The last day for entries is November 9, and full particulars may be obtained from the Hon. Secretary (Mr. Geo. Scott), 30, Cobden Street, W. Hartlepool.

JARROW Camera Club.—The members of this flourishing society opened the winter session on Tuesday evening last with a smoking concert in the club room, Walter Street, Jarrow. There was a large attendance, presided over by Mr. E. W. Penman (president). The Secretary (Mr. W. Hanning) announced during an interval that the lecture season would begin on Tuesday next, when Mr. Reick would speak upon plate development.

A PHOTOGRAPHIC Society for Aberystwyth.—At a meeting held at the Congregational Schoolroom, Aberystwyth, presided over by Professor D. M. Lewis, it was decided to form a photographic society for the town and district. The following officers were appointed:—President, Professor Lewis; vice-presidents, Messrs. G. W. Cosens, E. H. Short, and Robert Ellis; secretary, Mr. F. A. Reid; and treasurer, Mr. Miall Jones.

BRENTFORD Photographic Society.—At the general meeting, held on October 4th, at the Baths, Brentford, the officers were re-elected with slight change. A record section was formed, under the directorship of Mr. Turner, F.R.Hist.Soc., with Mr. R. H. F. Hitchens as hon. secretary. This will be the last meeting of the society at the Baths. All future meetings will be held in the Free Library Lecture Hall, situated within three minutes' walk of the railway station (L. and S.W. Railway).

ADDRESS Wanted.—Mr. H. M. Fell writes from 57, 59, and 61, Clerkenwell Road, London, E.C.: "In your issue of September 20, on page 860, under the title of 'Spotty Prints,' Mr. E. Woodcock writes for some information with regard to the cause of spots on C.C. Paper. If you will kindly send me the address of this gentleman I believe that I can assist him in getting over this trouble." Will Mr. Woodcock communicate direct with Mr. Fell? We have not kept his address.

W. WARREN JEPSON, of 3, Cookridge Street, Leeds, Photo-Enlarger, Retoucher, etc., writes: "I am pleased to say that owing to a continued increase in the amount of business I have now added to my facilities for the execution of high-class work, and also for the quick dispatch of orders, by the fitting up of new and commodious premises, and that on and after the 17th inst. my address will be The Photographic Works, Hanover Street, Leeds. In future the style of the firm will be W. Warren Jepson and Co."

"THERE'S a fine thing going cheap which exhibition secretaries should carefully consider," says a writer in the "Yorkshire Weekly Post." "The Bradford Exhibition will shortly close, and the wall covering of the photographic section will be for sale, and should be secured by someone. It is olive green dull canvas and a grey frieze on which the pictures appear to great advantage. It really is a great chance, and

full particulars can be obtained from Mr. Alex. Keighley, Steeton, High Hall, Keighley.

SCOTTISH Natural History Society.—The fifth ordinary general meeting of the Scottish Natural History Society was held last Thursday night in the Society's Rooms, 5, Queen Street. A lecture was delivered by Mr. J. B. Mears, entitled "Photography and Nature," illustrated by a series of lantern slides from photographs taken by Mr. A. L. van Someren. The lecturer, after explaining the methods of work in different localities, showed numerous interesting slides, including sets of slides illustrating the life history of a bird, and the protective colouring of eggs and birds.

ILFORD Photographic Society.—On Monday last, at Cranbrook College, the annual general meeting of this Society was held. The annual report and the financial statement were satisfactory. Mr. Haslam was elected president. The vice-presidents were as follows:—Messrs. G. W. Barnes, Brand, Whitelaw, Mann, Galledge, Frost, W. N. Beale and the Rev. J. W. Eisdell. Mr. H. Cole was elected secretary and treasurer, with Mr. Perritt as assistant. Mr. Hornby was elected hon. lanternist, and the committee was appointed as follows:—Messrs. Aldons, Hall, Radford, Rotherham, Williams, Eames, Heyman, and Hill.

A PHOTOGRAPHER was preparing to take a view at the top of Duncan Street, Manchester Road, Bradford, on Monday last, when a man named Patrick Fogarty went up to him and dashed the camera to the ground. He was running away, when P.C. Blackburn caught him, and a struggle ensued, in the course of which Fogarty kicked the constable on the legs and body. For this assault he was committed for four months, with hard labour, at the Bradford City Police-court, and an additional month's imprisonment was imposed for breaking the camera. He had been twenty-one times previously convicted, six being for assaulting the police.

ENSIGN Film Competition.—Houghtons, Limited, ask us to draw attention to the fact that the current month (October) closes for the present this competition. The awards in the September competition are as follows:—(1) £10, Miss Dora Messow, Brandon, Holly Walk, Leamington; (2) £5, Sergeant T. J. Moore, 17th Lancers, Pier Hill Barracks, Edinburgh; (3) £1, Mr. A. Best, 60, Whippingham Road, Brighton; (4) £1, Mr. R. Lawrence, Craigroyston, Oban; (5) £1, Mr. F. A. Garratt, 6, Wolverton Avenue, Kingston Hill, Surrey; (6) £1, Mr. W. Lapping, Gilford, co. Down, Ireland; (7) £1, Miss G. Wilmot, Mickleton, Chipping Camden, Glos.

ROTHERHAM Photographic Society.—At the fifteenth annual meeting, on Tuesday last, officers were chosen as under:—President, Mr. E. Isle Hubbard; vice-presidents, Messrs. J. Leadbeater, W. Firth, and J. W. Stamp; hon. treasurer, Mr. F. Oldham; hon. secretary, Mr. H. C. Hemingway; assistant, Mr. C. E. Davis; auditor, Mr. Davison; curator, Mr. F. Sargeant; members of Council, Messrs. W. Mason, J. C. Cox, F. Thomlinson, and F. Sargeant. The report of the year's work was exceedingly satisfactory, and there was an increased balance in hand. It was announced that Lady Holland would open the annual exhibition. Mr. J. Leadbeater gave an address on "The Photography of Lightning."

R.P.S. "RED BOOK" Night.—We would again draw the attention of members of affiliated societies to the special meeting arranged for them to-night (Oct. 14) at the New Gallery, Regent Street, London, W. The Committee of the Royal Photographic Society believe that members will welcome this opportunity of fraternising and of viewing the forty-ninth Annual Exhibition. As already announced, there will be no charge for admission, the Council of the R.P.S. having promised free admission to every member producing his "Red Book" or the special red ticket issued by the Executive Committee for the current year. The reception of visitors by the Executive Committee will commence at seven o'clock. At eight o'clock there will be an address by the Chairman, followed by an exhibition of the competition slides and slides in natural colours by various processes.

RICHMOND Camera Club.—The autumn session of this club opened on Thursday evening last week, when the members were informed, to their great regret that the hon. secretary, Mr. E. G. Richardson, had been obliged, after many years of valuable work for the club, to sever his connection with it in consequence of his removal from Richmond. Mr. J. A. Abbott, of St. Leonard's House, East Sheen, who has been acting as hon. secretary pro. tem., was appointed to the office. After

transacting the business incident upon the opening of the new session some slides brought by members of the club were passed through the lantern. These consisted of various landscapes by Mr. Bretherton, views of Ludlow, the Wye district, etc., by Mr. Cheese, some do photographs by Dr. Rodman, followed by some of his radiographs of shells and views taken during a motor car trip in Northamptonshire.

EDINBURGH Society's Exhibition.—The annual exhibition of the Edinburgh Photographic Society is to be held later this session, and will open on February 25, 1905, which is about three months later than last year. There will be two sections, as before, one for members work and one open to all. In both classes medals will be awarded at the discretion of the judges. The Society have also arranged a syllabus for the general meetings and the practical evenings, which will carry them on until May. The opening meeting of the session was held last week in the rooms, 38, Castle Street, when Mr. J. Tudor Cundall, B.Sc., the new president, delivered his inaugural address. He discussed photography in three aspects, that of simple representation, a vehicle for pictorial representation, and as an aid to scientific research.

THE Art of the Showman.—"The camera cannot lie" is a saying nearly as old as photography itself, remarks a writer in the current number of "The Easy Chair," but, if this is correct, its animated brother is certainly not its equal as regards veracity, as the following will prove. A certain showman had booked a hall for the exhibition of animated pictures in a small town in Ireland, and, going over to complete preliminary arrangements, he discovered, some what to his chagrin, that a strong pro-Boer feeling existed among the inhabitants. Now, he had announced upon his bills that all the latest pictures from the theatre of war (the South African War was in progress) would be shown, and great excitement prevailed in anticipation of the event. Of course, such pictures as he had were entirely in opposition to the opinions of his patrons, but the wily showman was equal to the occasion. He quickly arranged several faked scenes depicting unfortunate Boer prisoners being maltreated by brutal English soldiers, and other pictures of a similar character, and so realistic were they that a certain Irish newspaper, whose name it would be unfair to divulge, actually printed an article demanding that a Government inquiry should immediately be held to discover and punish the perpetrators of these foul outrages!

SATURN'S Smallest Sister.—In 1899 it was announced that Professor W. H. Pickering had made a discovery (the first of the kind by the aid of photography) which, if confirmed by subsequent observation, would add a ninth satellite to the known cortege of the planet Saturn. It is interesting to note, therefore, that Professor Barnard has recently caught a further glimpse of the tiny moon, on whose real existence some doubt had begun to be cast. To this new world Professor Pickering has given the name of Phœbe, a sister of Saturn or the shining one. This title is something of a misnomer either way; it is regarded; the "sister" is a little creature with a diameter of probably no more than 200 miles, while that of her giant "brother" is 69,780 (polar), or 76,470 (equatorial). As for "shining," Phœbe is the faintest body in the Solar system, have an estimated magnitude of less than 16, which may be better understood when it is remembered that from Sirius to naked eye invisibility is but six magnitudes, Phœbe thus being, of course, ten such stages fainter. Even from Saturn, the newly-found satellite would be beyond naked eye range! Let it not be thought, however, that this latest planetary discovery is unimportant. Faint as she is, Phœbe is the largest body found in the Solar system since October 24, 1851, when Lassell discovered Ariel and Umbriel, the two inner moons of Uranus.

ATTACHING Banking Accounts.—An interesting point affecting banking accounts was heard in the City of London Court the other day. Bassano's Studios, Ltd., Old Bond Street, have recovered judgment for three guineas and £1 4s. costs against Mr. W. T. Masterman, Horsemonden, Kent, for photographs supplied. Then Captain W. S. Masterman, of Tunbridge Wells, wrote to the plaintiffs, and sent cheque on the Tunbridge Wells branch of Lloyds Bank for three guineas, saying that he knew nothing of the legal proceedings. The plaintiffs now sought to garnishee the banking account for £1 4s., the unpaid costs; and they said that Mr. W. T. Masterman and Captain W. S. Masterman were one and the same. The solicitor for Lloyds Bank said that this statement was not true. Captain W. S. Masterman and a Mr. Miller owned the account at the bank. They could

not allow the account of a man who had never had anything to do with the plaintiffs to be attached. The plaintiffs' solicitor said that they were entitled to attach the account and inquire into the amount standing to the credit of the man who owned the money, otherwise creditors would be set at defiance. It was a most lamentable state of affairs. Judge Rentoul, K.C., agreed, and said that the request seemed to be reasonable, but there was no legal machinery enabling it to be carried out. Judgment must be given for the bank on the garnishee summons, but the plaintiffs could have a receiver appointed.

The Salon from an Art Standpoint.—Commenting on the twelfth annual exhibition of the Photographic Salon, the writer of *Art Notes* in the "Illustrated London News" says the colour of the prints themselves, their mounts, and the charming simplicities of the wall all tend to give the gallery an atmosphere of good taste, but, to be frank, hardly more; and hardly more is expressed by the photographs themselves. Vehement as are the photographers of to-day in declaring that their occupation is an art pure and simple, it is hard to follow the argument that is designed to prove it to be so. Scope for good judgment and scope for a refined taste are ample in work with the camera, but these qualities are only attendant on the great talent, so to speak, of the camera itself. It is the instrument's point of view which is pervading every photograph, and this individuality is fully as strong as that of any photographer. Here then is the difficulty. The main effort of the more advanced photographer of the day, as exhibited in the two London exhibitions, is to stamp out the mere mechanical work of his instrument. By changing tones here and there, heightening this and lowering that, he gains a result which has obviously something to do with the human hand, but which is necessarily without the impulse and completeness of entirely original work. Nor is this result a complete photograph, for the truth as expressed by the camera only shows itself in the spaces untouched by the photographer.

Kodak Pictures of Macedonia.—Kodak, Limited, have arranged at 115, Oxford Street, a little exhibition of enlargements from photographs taken by Professor P. N. Milnkoff, a Russian historian, during a recent journey in Macedonia. The original negatives were all taken with a No. 1a Folding Pocket Kodak. Due allowance being made for the woolliness which is inseparable from an enlargement, the seventy-nine pictures in this exhibition give a very fair idea of the scenery and national costumes of the lower half of the Balkan Peninsula. The photographs of the "Iron Gate" on the River Virdar, between Salonika and Uskub (No. 12), and of the lake of Okhrida (No. 19), show that, if a satisfactory solution of the Near Eastern problem can be found, the Macedonian vilayets—and the same is true of a large part of Bulgaria—have many charms to attract the tourist. Nos. 13, 60, and 67 illustrate the methods of threshing commonly employed by the Macedonian peasants. The corn is strewn upon an earthen threshing floor and crushed by a roller drawn by the pretty little white oxen to whose share falls a large part of the farm work of the Balkans, or trodden out by the hardy little ponies which trot round the floor roped to a stake in the centre. A number of groups of peasants display the picturesque costumes which have not yet been displaced by slop clothes from Central Europe, and No. 60 gives a most humorous portrait of a khamal or porter in Bitolia. The whole exhibition can be seen in a quarter of an hour.

The Members' Year Book for 1904-5, just issued by the Southampton Camera Club, is again this year an excellently bound little directory of photographic dealers and manufacturers. The programme of fixtures for the ensuing winter is also included, and in addition to this a real photograph by the energetic Hon. Sec. serves both as a frontispiece and as an advertisement for a well-known gaslight paper. We are particularly pleased to see that Mr. Kimber is making a step in the right direction in the compilation of the season's programme by securing the services of such well-known lecturers as Messrs. F. Martin Duncan, O. G. Pike, Charles B. Howdill, H. C. Shelley, A. J. Kay, C. H. Hewitt, E. W. Harvey Piper, and F. Ormiston Smith. These names, among many others amply point not only to a successful and instructive series of evening meetings for the members of the Southampton Society, but also discloses the fact that an equally successful year has been passed. We commend the example of this association to many others throughout the country, and feel sure that the introduction of a first-class programme of lectures and demonstrations by experts at first hand will repay a hundredfold in increased

membership and vitality any expenses attached to the venture. The Year Book also includes among other interesting items several blank pages for notes, rules of the Society, places to photograph, and list of members, etc. A black lead pencil is attached to the volume, without which we feel sure no member of the Club would think of venturing forth on a photographic expedition.

PHOTOGRAPHIC Survey of Sussex.—The photographic survey of Sussex is making progress, and some photographs of great interest have been received, notably those from Mr. Gerald Loder, M.P., Canon Cooper, of Cuckfield, Mr. W. H. Hills, and Mr. Alfred Roods. It will be remembered that the photographic survey of the county was only decided upon at the last annual meeting of the Sussex Archaeological Society, when a Committee was appointed to carry out what will probably prove to be a very important undertaking. The Committee desire that all who are able will endeavour to contribute to the collection of photographic records now in progress, and it is hoped that a large number of amateur photographers and others will take this announcement as a direct appeal to them to assist the Committee. The subjects for recording photographically are those that have any county interest—not only old buildings, as now existing, but photographs of them taken from old prints, paintings, drawings, etc., also photographs of old documents, books, maps, etc., historic trees, landmarks, etc., while especially to be desired are photographs illustrating old customs, some of which are dying out, e.g., mummers, Jack-in-the-green, the doll, May-day, maying, the game of stool-ball, etc., whether taken from the life or from old drawings. The Secretary would be glad to know beforehand of such occurrences with a view to their being photographed. The Committee of the Photographic Survey also desire to obtain as members those who are willing to undertake work in a small section of the county. Donations would be very acceptable to meet the unavoidable expenses. The Hon. Secretary and Treasurer of the Survey is Mr. J. C. Stenning, Steel Cross House, near Tunbridge Wells, who would be glad to give any further information, and to him all photographs, etc., should be forwarded.

BIRMINGHAM Photographic Society.—The following are extracts from the annual report:—The membership roll now stands at 177 (inclusive of 27 new members) as compared with 191 last year. More new members are needed, and your Council earnestly request the hearty co-operation of all members in obtaining a larger number of new members during the coming year. Increased membership means increased spending power, and therefore increased facilities for all members. The two new cameras, size 12 by 10 and 15 by 12, purchased and available for members' use, have been much appreciated, having been loaned to members on twenty-seven occasions, exclusive of periods when in use on society excursions. Success has again attended our members at the exhibition of the Royal Photographic Society, two medals having been awarded, one each to Mrs. G. A. Barton and Mr. W. A. Clark. After twenty years' membership of the present Society and thirty years' membership with the older one, Mr. W. B. Osborn has been elected an honorary member. Your Council feel assured the members cordially thank Mr. Osborn for his long services, and wish him continued years of prosperity and good health. The best thanks of the Society are due to Mr. A. J. Leeson, who has so ably filled the office of President during the past year. All who attended the conversazione and garden party so generously given by our President will unite in expressing their thanks for the kindly and courteous treatment extended to them. Mr. H. Vought-Cornish having resigned the post of Honorary Secretary to the Society, your Council desire to place on record their high appreciation of the valued services rendered by him in that position since April, 1900. Much of the recent success of the Society is due to his untiring efforts, and the members will join the Council in wishing Mr. Cornish many years of continued membership, if in a less exacting position. **Warwickshire Survey.**—The curator reports having now in hand 106 prints (from five new contributors). These were collected previously, and shown at the B.P.S. Exhibition in February last, and, although a fair average, the number is not nearly so great as last year, when several members contributed largely in local subjects. In March last, prints to the number of 468, on 407 mounts, were handed in to the City Library for safe keeping—a selection of the more interesting having been previously exhibited in the City Art Gallery by the kindness of Mr. Whitworth Wallis. The curator will be pleased to receive contributions of prints of any of the following for the survey:—Old Broad Street Corner, old Congreve Street, old Queen's College.

Correspondence.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

THE PROFESSIONAL PHOTOGRAPHIC ASSOCIATION AND THE PROPOSED BENEVOLENT FUND.

To the Editors.

Gentlemen,—I fear, from your note appended to Mr. Watson's letter (p. 878) that you may think me guilty of claiming some originality for the suggestion that the P.P.A. should start a Benevolent Fund. Far from doing so, I took it for granted that every one knew this to be one of the ultimate objects of the Association, laid down in the inaugural address by Mr. Thomas Bedding. Further, I believe it is generally known that the Association, and especially Mr. Lang Sims, has devoted much thought and time to solving some of the undoubted difficulties in the way of managing a fund that shall work satisfactorily. My own effort was merely to re-awaken the interest; and if there was any new suggestion from me, it was in the idea (which I here and now slightly amplify) of a joint committee. I know (from painful experience) the troubles of the old "Benevolent," and something of the difficulties of the P.P.A., and those which faced the Royal, when it was asked to take over the work, and suggest that many of these difficulties could be overcome if the Councils of the P.P.A. and the Royal would each undertake to nominate six persons each year to serve as members of a "benevolent" committee, which should be strengthened by (say) six other members elected annually by subscribers to the funds. In this way we should get some assurance of a permanent committee which would command the respect of every section of photographers.

Since re-raising the subject I have had most encouraging letters from important firms of manufacturers and dealers, and from gentlemen of the highest standing in connection with photography, promising generous support if they can be assured that those for whom the benefits are mainly intended (the professionals) take a real interest in the matter and are prepared to do their part. Of this I think there can be little doubt, if the few professionals who have written me upon the subject are at all fairly representative of the opinions of the craft.

The P.P.A. has shown its practical interest by arranging to devote almost the whole of its meeting on October 21 to the discussion of this subject. At the invitation of the Secretary I hope to lay before the members some interesting particulars of the work (and difficulties) of the old "Benevolent," and if only a hundred professionals will follow the lead of Mr. Frank Watson by writing to you or to the P.P.A. to promise even a small amount of regular support a new "Benevolent" will be undoubtedly started, and on sound lines.

It is truly heartrending to know some of the cases of genuine distress, and at the same time to know that considerable funds are available if only an organisation can be formed to collect and properly administer them. The support of the professional is the one thing needful, and I cannot believe that his attitude will long continue to be that which was put into words by one of the craft: "Let the beggars go to the workhouse." There are some disgraces to the profession for whom even the workhouse seems too good; but—there are some honest, anxious strugglers who should never be allowed to drift to that haven.

Whether the problem shall be hopefully, helpfully tackled this winter, or shelved for at least some years will probably depend upon the action of your readers between this date and that of the next meeting of the P.P.A. Is it too much to ask them to write a note and promise a small subscription?—Yours faithfully,

H. SNOWDEN WARD.

Hadlow, Kent, October 7, 1904.

[Our comments on Mr. Watson's letter were designed not for the purpose of disputing the originality of Mr. Ward's suggestion, but to remind the former gentleman and professional photographers generally that the machinery for the administration of a Benevolent Fund—if such can be formed—had been in existence for over

three years. While on the subject we may say that we find ourselves unable to endorse the idea that the co-operation of the Royal Photographic Society should be sought in the matter. The R.P.S. has already on hand more work than it can get through with efficiency and expedition; and, besides, does not, in our opinion, exist for the purpose of promoting benevolence. Moreover, joint committees selected from bodies having no real community of interest rarely work well together. At the risk of being charged with undue reiteration, we must again urge—as we have urged before—that the initial action in the establishment of a Benevolent Fund should come from professional photographers themselves through the representative body, the P.P.A. Finally we ask, as we asked September 2: "Who will come forward to help?"—Ems. B.J.P.]

To the Editors.

Gentlemen,—Not long ago it was the practice of some of our monthly magazines to give us such information as: So many pieces of lump sugar placed end to end would reach Australia; or, so many boxes of lucifer matches put one on the other would reach the moon. This seemed very wonderful, but was really a very simple calculation, easy to make, and not difficult to verify, on paper.

In some such arithmetical frame of mind Mr. Frank Watson, Brighton, in your last number, has calculated that if the members of the Professional Photographers' Association, 500 strong, subscribed 5s. each, it would produce £125 per annum; and further, if the same number paid 6d. per week it would realise £650 per annum. So far so good. Mr. Watson is presumably a member of the Association, but probably he has not had much experience in collecting annual subscriptions, and I am afraid he knows little of the circumstances or inclinations of the average professional photographer.

There is an old story about a little girl who while at school had this question put to her: "If I lent your father £100 at Christmas, and he were to repay me at the rate of £25 every three months, how much would he owe me in July?" The pupil answered promptly: "£100." "No, no," said the teacher, "you evidently do not understand my question." "Oh, yes, I do, miss; but you don't know my father."—Yours truly,

London, October 10, 1904.

To the Editors.

Gentlemen,—Referring to Mr. Watson's letter in the "B.J.P." of last week, I should like to make a practical suggestion which would, I think, materially help the members in discussing the Benevolent scheme at their meeting on the 21st inst.

Let those members willing to subscribe 5s. a year, and 6d. per week (as proposed by Mr. Watson) or any other sum, to a Benevolent Fund, kindly communicate the fact to the Hon. Sec., P.P.A., 21 Baker Street, London, W., before the date of the above meeting.

Thanking you in anticipation I remain, dear sirs, yours truly,

F. A. BRIDGE.

Dalston, October 8, 1904.

SHANGHAI AMATEUR PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—Arrangements are now being made for the annual Photographic Exhibition in connection with the above society, to be held about the end of this or beginning of next year. It is proposed to devote one section to the interests of photographic manufacture and dealers, and makers are invited to send samples, specimens of work done with their product, catalogues, and anything likely to be of interest, and at the same time advertise their goods.

The exhibition will be held in one of the largest buildings here, and one particularly suited to the purpose. Ample room will be available for the proper display of all exhibits. We hope to be able to pass all exhibits received in this section to exhibitions held by other societies in China and Japan, but this is only in the case of those following our date. We may mention that the exhibitions of this society have become one of the most popular events of the year here, and are visited by large numbers, people not only resident, but tourists and others passing through, of which there are always a large number. While making no charge of any kind for space, we cannot bear more than local expenses. We think that the small cost to makers of sending out here will be a good investment as an advertisement.

ment of their goods. Exhibits should be addressed to the under-
signed, and reach here as early in December as possible.—Yours
J. HERVEY LONGHURST, Hon. Secretary.
Shanghai, September 1, 1904.

PRINTING TINTED BORDERS ROUND P.O.P. OR BROMIDE PRINTS.

To the Editors.

Gentlemen,—I tried some months ago a method described in one
of the photographic magazines of printing borders, and do not find
it so easy and accurate as my own method, which I venture to
submit that you may test it if you think it likely to be of any use
to others.

It is necessary to use a printing frame with open ends, i.e., flush
with the rebate on which the glass rests.

The foundation of the method is the guide card for cutting the
masks, and I make it as follows: Cut a piece of good stout white
mounting card to fit the printing frame easily but closely, with a
piece extending to the edge of the frame at one end to take the
guide pins A.A. (see diagram); place the card in the frame drive
two stout pins through the projecting end well into the end bar of
the frame, and cut off sufficient to leave about half an inch project-
ing. Before removing the card from the frame make a line round it
with the front close to the frame, draw central lines horizontally and
vertically from which to lay off lines marking the sizes of masks
you intend to use, and at the corner of each puncture the card
with a pin. We are now ready for cutting the masks. Take as
many pieces of stout paper as you will require for the style of
order you wish to print, place them one upon another with the
guide card on top, and cut them accurately to size of card, taking

care they do not shift from their position; pierce them through
each corner hole in the guide card at the size selected and through
the guide pin-holes. The holes pierced in the pieces of paper will
mark where lines are to be drawn for cutting the masks. You will
now find that you have masks which can be removed and replaced
exactly in their original position.

To enable the printing paper to be taken out and replaced in
register, cut a strip of card of the width of the other end bar of
the frame, place it in position, drive two pins through it into the
end bar and cut off to the same length as the guide pins A.A. Now
place the printing paper on the clear glass in the frame, spread
some Higgins' mountant on a strip of paper, press it down on the
printing paper and strip of card to hold the two together. The
mountant will dry in a minute or two without any damp striking
through the paper.

Take the mask cut to the size the picture is to be printed, place
it on the guide pins, and with a little mountant attach the central
portion to the clear glass to hold it in position for protecting the
centre of the paper while the border is being printed. When you
have printed the borders place another piece of clear glass in the
frame, adjust the outer mask, then the negative, and finally the
printing paper with guide card attached by means of the pins at
the other end of the frame.

I can cut a guide card and masks in much less time than it takes
to describe the method.—Yours faithfully,
October 6, 1904. M. G.

NOTHING LIKE BUTTONS.

To the Editors.

Gentlemen,—Your correspondent's reference to sweating and
decreasing salaries, under the heading "Nothing Like Buttons,"
must have made many assistants smile who have had the honour of

working there (Liverpool) during the last twenty years, and they
could be counted by hundreds. Truly, when the Devil is ill the
Devil a saint will be. Higher prices are being obtained to-day in
this city for cabinet photos than was the case fifteen years ago.
With regard to profit, when you see the mushroom men who do three
retouched cabinets for 2s. 6d. and twelve promenades for 10s. 6d.
smoking big cigars and driving their motor-car one is inclined to
think that there is some profit in photography yet.—Yours truly,
Liverpool, Oct. 10, 1904. ARGUS.

[We are glad to hear that photography in Liverpool is so prosperous
as our correspondent makes out, but we think he might have stated
his case without the introduction of veiled personality.—Eps. B.J.P.]

SOME PECULIARITIES OF DYES WHICH PRODUCE TOTAL SPECTRUM SENSITIVENESS.

To the Editors.

Gentlemen,—Mr. Thorne Baker's article under the above title
is open to a good deal of criticism.

In the first place new patent blue was first tested as a sensitiser
by Valenta (P. Corr., 1897, pp. 129, 185). The same author also
states (P. Corr., 1900, p. 99) that woolblack 4 B gives a broad band
of sensitising action from A to D, and with long exposure a second
indistinct band from D $\frac{1}{2}$ E to beyond E, therefore this rather
knocks the bottom out of Mr. Baker's theory, as the yellowish
green is included in the region from D $\frac{1}{2}$ E to E.

I have already drawn attention to the fact that this dye was
practically used by Dr. Eder's Institute in three-colour work.

With regard to Titan-scarlet, one can only assume that he refers
to Titan-scarlet S, which was also tested first by Valenta (P. Corr.,
1901, pp. 231, 490), there being four varieties of this dye. Mr.
Baker makes this an exception to his theory. As the absorption
of this dye is in strong solution from C $\frac{1}{2}$ D to H, and as it sensitises
for the same region, the exception hardly holds.

I am not quite clear as to the exact meaning of the first sen-
tence in his article at the top of the first column on p. 868, but if
he means that a fluorescent dye does not exert a screening action
he is quite wrong, as one has only to add enough of any of the
fluorescent eosine group to obtain a strong screening effect.

Mr. Baker also states that new patent blue forms "a 'screen'
through which all rays but yellow-green pass, hence these are the
rays to which the plate is least sensitive." I presume he used this
dye, like the other two, in a solution of 1:100,000. Unfortunately
for him Dr. Eder ("Spectralanalytische Studien über Photo-
graphischen Dreifarbendruck," 1902, pp. 20, 21, and 22) gives the
absorption of this dye for the spectrum, and determines it for every
four wave lengths, and when used in a cell of the same internal
thickness as Mr. Baker's, but with a strength of solution of
4:100,000, that is, four times as strong, he shows that the total
absorption extends from λ 635 to λ 596, or from nearly C to D, the
whole of the yellow and yellow-green being transmitted, though
weakened; but the very region where there is total absorption is
the region where the strongest sensitising action of the dye exists.

Again, in 1884 Dr. Eder pointed out that the maximum of sensi-
tising action of an eosine-dyed film differed only by 16–20 μ from
the maximum absorption of a sheet of gelatine stained with
eosine.

Further, it would be interesting if Mr. Baker would explain on
the ground of his hypothesis the action of orthochrom T, which
shows two absorption bands with maxima at about λ 560– λ 573
and λ 520– λ 525, yet this gives three maxima at λ 589, 527, and
480 with a short exposure, but with a little longer exposure a closed
band from C to "little h." Would it be possible to explain the
action of nitrosodimethylaniline which in a strength of 1:7,500 shows
a strong absorption from F to K, but sensitises from D $\frac{1}{2}$ E to
about N?

Surely what applies to the less refrangible rays should be applic-
able, if a law, to the more refrangible; but if both ends of the spec-
trum are considered, Mr. Baker's law is the exception and the excep-
tion the law.—Yours faithfully,
Foot's Cray, October 8, 1904. E. J. WALL, F.R.P.S.

HALF HOLIDAYS FOR ASSISTANTS.

To the Editors.

Gentlemen,—I should be greatly obliged if you would let me know
if the following matter is correct. I have been informed that by a

new Act, from New Year, "employees are entitled to leave work at two o'clock on one day a week." Does this apply to photographic assistants? I inquire on behalf of fellow-assistants (and self) who are employed in photographer's workroom where the hours are from 9.30 to 7.30 the entire week, thus such an alteration would be highly appreciated, if permissible, without loss of salary.—Yours most respectfully,
E. LACEY.

Filmer Road, Fulham, S.W., Oct. 10, 1904.

[We are unaware of any Act of Parliament which seeks specifically to regulate the hours of labour of photographic assistants. Will some legal reader enlighten our correspondent on the point?—Eds. B.J.P.]

THE ART OF DISCOUNTING THE HANDICAP OF THE CAMERA.

To the Editors.

Gentlemen,—A visit to the Photographic Salon must have set many longing to be able to produce such masterpieces of beauty as adorn its walls, which proclaim so convincingly that, despite a camera, a man—more especially an American—can yet be a true artist. It is, therefore, the writer's desire to satisfy those longings by imparting some instruction which shall disclose the secrets of genuine photographic art as secured by triumphing over the limitations imposed by the camera. Those who, before trying to produce a "Salonograph"—to coin, as a deserved mark of distinction, a distinctive term—have used a camera, etc., in the ordinary way will be more handicapped than the absolute tyro who has never before attempted photographic work. This is so because, in order to attain to any excellence in Salonographs, it is absolutely necessary to unlearn all that has been previously learnt of that bastard photography which has also done duty so long for the genuine article only lately brought to light by the Salon. It cannot be too frequently insisted that slavish technicalities have *nothing whatever* to do with the successful production of Salonographs, which, as art pure and simple from beginning to end, are far above any such galling restriction, and have no more in common with ordinary photography than night has with day. Consequent upon this, it follows that, in order to produce real pictures, it is of little moment what sort of camera one uses so long as it fairly fulfils the offices of what is ordinarily accepted as a camera, and is not too light-leaky. As regards a lens, the Salon artist knows better than to waste his money on lenses which are merely optical combinations made to the absurd formulæ of opticians. On the contrary, he will make a point of purchasing some lens which a mere optician, unversed in the requirements of an artist, is pleased to term "defective"; for, the more defective an optician deems a lens, the more effective will a Salonographer consider it. A lens distinguished for "flare spot," or chromatic or any other aberration, can be heartily recommended as capable of producing truly wonderful results, for the flare spot will always come in very effectively as the sun or moon. Having satisfactorily selected so much apparatus, there is now the subject to seek, which should be what ordinary people, in their ignorance, would term "ugly," or "devoid of interest," or "meaningless." If the artist lean to landscape, very successful ones may be secured by selecting one commonly (but, of course, erroneously) accepted as "beautiful," and then setting up the camera behind something—preferably tree-trunks—which will wholly obscure the scene, and photograph these latter. If figure studies are preferred, of course the great thing is to break away from conventional treatment. Whereas the ordinary soulless portraitist points his lens at the face of the subject, the Salonographer will make his portrait study of the back of the head. In all cases the golden rule to be observed is to avoid falling into the fatal mistakes made by the absurdly-termed Old "Masters." The Salonographer has nothing to learn from their works, and anything termed "good imposition" or "art rules" should be as much shunned as one shuns the pages of the *BRITISH JOURNAL OF PHOTOGRAPHY* itself. As regards the question of plates, since these must be used, the staler they are the better will be the Salonograph. There is nothing like buying up all the oldest plates obtainable—in fact, they should be advertised for—and it need not be remarked, since make and speed are of no concern to art photographers, that it is a matter of no moment what may be their description. "Stale" plates, as they are amusingly called, are just ripe for Salonographs, as they develop

a variety of pleasing spots and striking markings, which inevitably enhance the art value of anything taken on them. Focussing is unnecessary operation which may be wholly ignored, while in matter of exposure the artist will please himself how much he gives as it is of really no consequence how long the plate receives, though possibly too long is preferable for Salonographs of the best. Development follows exposure, but need not exercise the artist greatly, always supposing he refuses to put into practice the absurd mechanical theories compounded by the mere chemist. The plate can be developed in anything that can be had to hold it, and, being stale, is best treated with some stale developer—it is immaterial what it is composed. The Salonographer simply dashes on developer, and, when he thinks the plate ought to be developed, replaces the developer with fixing solution. It need hardly be marked, especially with water at its present price, that washings superfluities which need waste neither time nor water. When the plate is thought to be fixed it should be dried without further bother, and then will be ready for printing—the only process wholly satisfactory to the artist, since his individuality and his genius are not hampered by any tiresome mechanical restraints. Any grainer will supply some of that white paper in which he wraps his bisulphur sugar, and this is prepared for printing with a mixture of glue and soot sensitised. Next a piece is torn to size (for it goes without saying no artist would demean his art by employing scissors), and this the print is made. In the development of these beautiful grainer soot prints the great aim of the Salonographer is to remove, with a nice bristly brush, all traces of any photographic action. Obviously it is in this operation that one's art is proclaimed, and, exercising this great gift, a beautiful picture will result. Naturally, the print will be so pleased with his work that he will desire to exhibit it. This is a simple matter. Any piece of paper nearest to hand will serve as a mount, to which the print, with its charmingly irregular edges, can be affixed with any sticky substance. The print, ready for mounting, is let fall on the print, and wherever it falls it may be rubbed down, as commonplace mounting must be avoided at all costs. As regards the proportionate size of mounts to prints, a size of paper 18 in. by 10 in. will suffice for a picture 2½ in. by 3 in. The finished picture should be framed in some plain wooden box which will just hold the glass and no more. The finishing touch will include the pricing and titling. An excellent way to find a suitable title is to open some book—any book will do—haphazardly and settle on the first few words which meet the eye. As to pricing, all the trouble and art the Salonographer will have expended on his work makes his effort valuable, and he should be careful not to undervalue his productions. Ten pounds is a moderate sum for an Englishman to ask, but if the author be so fortunate as to be an American he will ask at least £15 15s. One must confess to Americans seem to make much more successful artists than Englishmen. This is evident from the selections made by the only competent photographic art tribunal in England. However, there is no saying what success might not be achieved by any Englishman who, anxious for the recognition of his toils, assumed an unmistakably American *nom de plume*. Those whose works so far have proved unacceptable to the Salon are advised to let their art in the future include this simple experiment.—I am, yours, etc.,

Oct. 10, 1904.

A COMPETENT ARTIST.

[Our correspondent is a successful exhibitor of what may be termed (in contradistinction to the productions which she—the writer—lady—criticises) straightforward technical photographs.—Eds. B.J.P.]

"THE SAME OLD STORY."

To the Editors.

Gentlemen,—Under this heading you drew attention last week a paragraph in the "Daily Express," from its Berlin correspondent on a new process of "coloured photography." The association of Dr. Koenig's name with the invention caused us some surprise, for its palpable absurdity made us nail the story to the counter as should a counterfeit coin. We are now able to publish a description of Dr. Koenig's process as it is given in the "Photographische Wochenblatt," and it will enable the photographer to form some definite idea of the invention from the practical point of view instead of the fanciful one of the "Daily Express."

Dr. Koenig, of the photographic department of the dye-works formerly known as Meister Lucius and Brüning, Höchst-on-Main, read a paper at the Meeting of Naturalists, held this year at Breslau, on his positive printing process of photography in three colours with leuco bases, which he calls "Pinachromy." It is assumed that you have three negatives, one for each of the colours blue, red, and yellow. For carrying out the positive process a suitable baryta paper is selected and coated with blue collodion, that is to say, a collodion in which a leuco basis is dissolved, which upon exposure to light gives a blue image. Paper coated thus, after drying in the dark, is exposed under the blue negative and then fixed by immersion in a bath of monochloroacetic acid for six or eight minutes. After it has been washed for ten minutes the picture is dipped in chromated gelatine and dried, the object being to separate the blue film from those above it. The picture, when dry, is coated with red collodion, repried, and printed under the red negative, which of course has been obtained with a green filter. Care must be taken that the prints are in register. The printing should be done in sunlight, if possible, and when exposed sufficiently the picture should be fixed and isolated as before. The same is done for the yellow image by coating with yellow collodion and printing under the negative obtained with the blue filter. The colour-print is then varnished.

At the conclusion of this description the Editor of the "Photographisches Wochenblatt" adds: "The account of this process given in the daily Press is very misleading to the public, especially regarding the price of the pictures made in this way. When it is said that the cost is little more than that of ordinary photographs, the public is led to believe that these pictures must be equally cheap. But this can only apply to the material. Yet the chief cost of a photograph is not that of the material, but the work expended upon it, and if a photographer has to produce three negatives and three prints of any object it is evident that the price of the finished picture must be at least three times that of an ordinary print from one negative. It must also be remembered that the process has its dark side in the fact that the three negatives cannot be combined in advance to ascertain their colour effect. Some small oversight may render the whole useless. Such statements do incalculable damage to the advancement of colour photography.—I am, yours, etc.,

PINACHROME.

October 10, 1904.
[An article on this subject by Mr. E. J. Wall appears elsewhere in the present number of the Journal.—Eds. B.J.P.]

SELLING OLD NEGATIVES.

To the Editors.

Gentlemen,—We notice that in last week's Journal that "E. S." wants to sell old negatives, and you could not tell him of a purchaser. We sell ours to Mr. Charles Bowen, 58, Grove Road, Holloway, N.—Yours truly,

H. DIXON AND SON.

112, Albany Street, London, N.W.

October 7, 1904.

THE RIGHT OF REPRODUCTION.

To the Editors.

Gentlemen,—"The Torquay Times" Photographic Competition closed on September 7. The result was declared on October 7, and the prize of £2 2s. has been awarded to a gentleman who submitted eighteen views with right of reproduction! No wonder that professional photography is in a bad plight.—Yours truly,

JOHN ROBERTS.

Torquay, October 10, 1904.

TANQUEREY IN CEYLON.

To the Editors.

Gentlemen,—By enclosed you will see that the Tanqueray portrait swindle is being introduced further afield, their operations in England being by now played out, I suppose. I wish you will write a small history about these swindlers in your next issue, and I will get all the Ceylon newspapers to take it over and so prevent the half-educated people of Ceylon from being swindled by these people.—Yours faithfully

A. W. ANDREE.

Hopetoun Studio, Colombo, September 22, 1904.

[The enclosure is one of the all too familiar circulars adapted for Indian perusal. Our advice to the people of Ceylon who are asked to patronise Mr. Tanqueray is: "Don't."—Eds. B.J.P.]

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

W. Dickinson, 4, Benson Street, Ulverston, Lancashire. Photograph of Holy Trinity Church, Ulverston. Photograph of the Operatic Theatre, Cottage Hospital, Ulverston.

D. Johnstone, 73, Wilmslow Road, Rusholme, Manchester. Two Photographs of St. Chrysostom's Church, Victoria Park, Rusholme, Manchester.

J. Taylor, 31, Carrick Street, Byker, Newcastle-on-Tyne. Photograph of Lord Charles Beresford Starting Football Match.

T. W. O'Haurahan, Parliament Street, Kilkenny. Two Photographs of Groups of Fels, Kilkenny.

J. Burton & Sons, 39, Loughborough Road, Leicester. Two Photographs of G. Van Felsold, M.A.

E. Fenske, 19, St. John's Hill, London, S.W. Photograph of Wandsworth Prison.

W. Knowles, 7, Hainworth Road, Woodhouse, Keighley. Photograph of First Electric Car at Ingrow.

C. H. Smith, 21, Avenue Road, Fordsbury, Transvaal. Photograph of the Bishop of Pretoria, Missioners, and Clergy of the Witwatersrand. Photograph of the Rev. C. J. Abraham, M.A.

H. H. Wring, 50, Railway Road Leigh, Lancashire. Two Photographs of Mr. W. E. Marsh, J.P.

OPERATOR.—Your ideas, however excellent in foundation, are so vaguely expressed that the publication of your letter would not advance the cause you have at heart.

FOGGED PLATES.—P. H. HILSON asks: "Could you tell me how I can recover a fogged plate which has been developed, fixed, and washed? Is the formula that you give in the 'Year Book' suitable for this purpose?" In reply: You might try it, but we are afraid you will not be very successful if the negative is badly fogged.

MINIATURES.—P. C. JACOB says: "I want to do some miniature tinting. Would you tell me whether I can procure the porcelain all ready sensitised, if so, kindly give address of firm?" In reply: We think that sensitive opal plates are not now made. Most miniatures on opal are now printed by the carbon process.

OPINION WANTED.—"MA CHERE" says: "I should be extremely obliged if you would kindly pass your opinion on the enclosed retouching, also what wage the same is worth." In reply: The work is tolerably good. With the present over-stocked labour market we can give no opinion as to what wages such work would command. Many ladies who do similar work would be glad of employment at 25s. a week, or less.

TONING BROMIDES.—T. CHARLES says: "The enclosed little print was sent me by a friend. I am an enthusiast as far as photography is concerned, and do a good deal of bromide printing. This print appears to me to be a bromide, toned. Could you tell me how this tone is obtained?" In reply: "Similar tones may be obtained on bromide paper by employing the hypo-alum bath—hyposulphite of soda, 9 oz.; alum, 1 oz.; water, 100 oz. Use at a temperature of from 110 deg. to 120 deg. Fahr.

INCANDESCENT LAMP.—H. FRANKTON says: "In the BRITISH JOURNAL OF PHOTOGRAPHY for March 11, 1904, you have a short article on a new incandescent lamp, the invention of Professor Drehschmidt. Could you inform me whether this lamp has been put on the market, and if so, where I could obtain full particulars about it?" In reply: So far as we are aware, the light has not been put upon the English market. There is the Kitson light, however, which is similar in principle.

COLOUR PHOTOGRAPHY.—"COLOUR PHOTO" says: "At the Royal Photo Exhibition are shown some colour photos by Davidson's process; they seem to be taken instantaneously. Can you tell me how this apparatus is constructed, and where I can buy one?" In reply: If you write to the exhibitor, he will, perhaps, be good enough to tell you where the apparatus may be obtained. His address, we see from the catalogue, is 105, Hythe Road, Brighton.

LENS QUERY.—"CARLISLE" says: "I have a lens marked as enclosed. It seems to be a triple lens, and can, I believe, be altered to several lengths focus. Can you tell me what sort of a lens it is, or give any information about it? I have seen thousands of lenses, but never one like this." In reply: This is an old lens that was introduced many years ago. The complete instrument is a portrait combination with two supplementary lenses, one to shorten and the other to lengthen the focus, when placed in the centre of the tube. This form is not, we think, made now.

STUDIO BLINDS.—BLINDS says: "We are thinking of altering the blinds in our studio, at present practically black, and replace by unbleached calico or white muslin. We notice in 'Bigeow's Album on Lighting and Posing' he recommends the latter, but could one get Rembrandt or strong-lighted effects with these? We think not; also the light will be difficult to control with such thin material, we should think. Before altering, we shall be glad of your opinion." In reply: All will depend upon the aspect of the studio, which is not stated. We should doubt, however, if strong-lighted effects could be got with muslin blinds in a strongly-lighted studio, whatever its aspect.

SPOTTY PRINTS.—T. P. M. writes: "Enclosed are two prints on — P.O.P., matt and glossy. You will see that some are covered with spots. I have tried everything to avoid this, but with no success. I may say that the spots show after the prints have been in the last washing water (for about thirty minutes) after the fixing. Do you think it is something in the water? I may also add that a few of the prints out of the same batch are quite free of this defect." In reply: From what you say we should suspect the water. Probably the spots are due to particles of iron rust in it. Try using water from another source if possible, that might settle the question.

LENS QUERY.—"PROJECTION" says: "(1) I have a cabinet portrait lens of 6 in. focus, and also a 6 in. Anastigmat lens. Will you kindly say which would be best adapted to the projection of lantern slides, used in conjunction with an ordinary 4 in. or 4½ in. condenser? (2) Also, has the portrait lens any advantage over an Anastigmat of equal focus for enlarging with or without a condenser?" In reply: (1) Much will depend upon the qualities of the lenses. The portrait lens will give the more brilliant image on the screen. (2) The only advantage the portrait lens has, is its greater rapidity, but the Anastigmat having a flat field will perhaps cover the plate better.

COLLOTYPE PRINTING.—"COLLO" (Leeds) writes: "(1) In your note on Mr. W. T. Wilkinson's lecture on plate-making, reported in your issue of Friday, September 23, he says that after experimenting he found it advisable to use a solution of dextrine. Can you give me the quantities of silicate and dextrine that Mr. Wilkinson advises? (2) What is the best, most practical, and most up-to-date book on colotype printing (both for plate-making and also machine work), and also where I shall be able to obtain it and the price?" In reply: (1) No proportions were given in the report supplied to us, so that we cannot answer this query. (2) "Practical Colotype," by A. W. Fithian; it may be had through any of the dealers; its price is, we think, half-a-crown.

BACKGROUNDS.—"E. J. P." says: "(1) I have just finished painting a background in distemper, and since it has dried, I find with rolling it up and down the work comes off in flakes. I used plenty of size in the work, and cannot understand why this should be. Would you recommend me to touch up the faulty places, and then give the whole a coat of size, or should you advise me to do the whole thing again with a proper back-

ground distemper? (2) Could you kindly give me a recipe of good background distemper, such as is usually employed by artists with this work?" In reply: (1) We strongly suspect that you have used too much size in the distemper, or that you did not size the canvas before applying it. We should advise you to do the whole thing again. (2) The backgrounds done by artists are usually in flatted oil.

STAINED PRINTS.—T. C. GODDARD says: "1. Please find enclosed a few prints which I am sending you for your opinion, please. The P.O.P. print is one out of a batch which has got stained after leaving the toning bath. The fixing was quite fresh, but had fixed a few artists' matt prints before the P.O.P. I should be glad if you would kindly let me know what you think has caused the stain, as it often occurs. The prints are thoroughly washed. 2. I also enclose some prints of negatives that I have tried to retouch, and I should be glad of your opinion of them. I may say that they are practically the first negatives I have retouched." In reply: 1. The cause of the stains is carelessness. The prints were not kept moving while they were in the fixing bath—they were allowed to stick together. 2. Very indifferent. We should advise you to get a little instruction in the work.

RESIDUES.—G. H. THAIN writes as follows: "I shall esteem it as a great favour if you will answer the following questions:—(1) Is it really worth keeping the washings from P.O.P. papers? A friend of mine, a photographer, kept his for a year throwing silver down with salt, he kept it very clean and sent it to his dealer, who forwarded it to Messrs. —, and he got a letter back saying there was nothing in it, and he got nothing for it. (2) What is the cheapest chemical for throwing down silver from hypo which has fixed plates, and how does it work? (3) Would it do to throw down silver from P.O.P.? (4) Is it really worth keeping hypo that has fixed plates?" In reply: (1) Unless you use a good quantity of paper the washings are scarcely worth saving at the present price of silver. (2) Sulphide of potassium (liver of sulphur); make a solution of it and add to the hypo solution, and the silver will be precipitated as a sulphide. (3) Yes. (4) Yes, if a large quantity of plates are used.

New Book.

"Photographische Bibliothek."—"Stereoscopie für Amateur-Photographien," second edition, by C. E. Bergling; "Das Photographieren mit Filmen," by Dr. E. Holm; "Anleitung zur Stereoscopie," by Dr. W. Scheffer. Verlag von Gustav Schmidt, Berlin.

We have received these three volumes of the "Photographische Bibliothek," published by Gustav Schmidt, of Berlin. The first and last deal with the theory and practice of stereoscopic photography. The volume by Dr. E. Holm relates to photography with films. We can confidently recommend them to our readers.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Meeting of the Affiliated Societies. The "Red Book" meeting of members of the societies affiliated to the Royal Photographic Society, at the New Gallery, Regent Street, on Friday last, October 14, can be marked down as a red-letter event in the annals of the organisation. Not only was the function—mainly the outcome of an endeavour on the part of the Executive Committee to foster friendly relations between the affiliated societies—highly successful in every way, but the astonishing number of delegates present during the evening, when the general public were not admitted; the enthusiasm with which they greeted the remarks of the chairman, Mr. C. H. Oakden, who briefly recounted the history of the "gathering of the clans," and the benefits and ambitions, immediate and prospective, of the affiliation; the friendly rivalry apparent during the exhibition of the competition slides sent in by societies in all parts of the kingdom, nearly all of whom had representatives present; and the fraternising that followed, point conclusively, not only to the keen interest taken in the present welfare of the parent society and its Annual Exhibition, but also to the healthy state of British photographic societies generally, the most important of which now owe allegiance to the R.P.S., and are able to tender their members the advantages offered by the affiliation. We hope the note of progress sounded so definitely on Friday night will find a robust echo during the ensuing winter. Signs of renewed activity amongst the societies near and far are not wanting, if we may judge from the programmes and lists of fixtures that reach us daily, and we see no reason why this meeting, having proved such a signal success, should not be the precursor of many similar gatherings that may *inter alia* help in a measure to solve the problem of providing, according to his own estimation, an adequate guinea's worth for the "country member" of the Royal Photographic Society.

* * *

More Rays.

It might be thought that discovery in the direction of obscure rays would be resting awhile; but still another set of rays is claimed to have been discovered by M. di Brazza, a student of Liège. Their results have been rendered visible to the outsider by the employment of orthochromatic plates. Professor Charpentier, of Nancy, had surmised that the brain is the seat of the emission of the N-rays, and M. di Brazza thinks he has proved it, and that his rays called I-rays differ from N-rays by being able to pass through moist substances. When an experimenter concentrates his will the I-rays from his brain cause changes of luminosity in a phosphorescent tablet. When his attention is not concentrated the light does not flicker. The rays are not emitted equally from every part of the head. They are nil at the forehead

B

and upper part of Brocas centre, increase at the temples and eyes, and reach the maximum behind the ears. A question of profound importance is hereby raised. If it be possible to produce a visible physical effect on objects external to an experimenter or operator, what ground is left to stand on by those who object to the idea that one person's mind is capable of influencing that of another without the ordinary senses of touch, hearing, seeing, etc., being brought into play? If M. di Brazza can bring his orthochromatic plate results into the court of science, and win a verdict in favour of I-rays, a most momentous epoch will have been initiated.

* * *

Hydroquinone Hydroquinone, which is manufactured in Living Plants, by the synthetic method of treating aniline with sulphuric acid and potassium bichromate, has been discovered by two French chemists to be a constituent of living plants. MM. G. Riviere and G. Bailhache point out that the ignition of certain vegetable matters or the distillation of certain extracts such as those of ivy or common ash, gives rise to hydroquinone, but they have found that the buds of the pear tree yield the substance in considerable quantities, without the aid of processes which may give rise to the formation of hydroquinone from simpler compounds. They extract the buds with 9 per cent. alcohol in the cold for several days. This extract, which is strongly green, they evaporate to a syrupy consistency and dilute with boiling water and filter. Part of the chlorophyll and the whole of the resinous matters are thus removed. The fluid extract which remains is shaken with ether at intervals during forty-eight hours; on evaporation, impure, coloured crystals of hydroquinone are left. They are purified by treatment with a little recently precipitated lead oxide, the lead removed with sulphuretted hydrogen and the filtrate evaporated and crystallised. The hydroquinone thus obtained can be still further purified by sublimation. Each kilo of buds yields three to five grams of hydroquinone, so that the process does not threaten to compete with the present methods of manufacture. The hydroquinone is most abundant in the pear buds during the period of most active vegetation, decreasing as summer advances.

* * *

Clouds. It often happens that the landscape photographer is confronted by such weather conditions that, while ordinary work is hopeless, he gets many opportunities of securing fine cloud effects. And, as we all know, negatives of clouds are extremely useful for combination printing—so useful, indeed, that such negatives in great variety can be purchased of the dealers. It is, of course, far better to be dependent upon individual effort in this matter, for it might so happen that two pictures with the same firmament over each might come into unpleasant competition. Although nearly every photographer who has had opportunity of doing much outdoor work will have accumulated a store of such negatives, we venture to suggest that not one in a hundred will have made any attempt to classify them. Apart from the needs of ordinary business, the photographer would find great interest in doing so. In the old text-books we find that clouds are classified into the four divisions suggested a century ago by Luke Howard, and most persons can recognise at a glance the particular division to which a cloud picture belongs—whether it be *Cirrus*, *Cumulus*, *Nimbus*, or *Stratus*. Such a simple form of classification, however, has not been found to entirely meet the requirements of modern meteorological science, especially since so much attention has been devoted to weather forecasting, for the prophet still relies in some measure, as of old, on

the aspect of cloudland for his prognostications. Howard's classification held good until 1891, when, at the International Conference held at Munich, a new one was proposed. This had already been foreshadowed in the cloud atlas of Hildebrandsson. Three years later another conference was held, and a very large assortment of cloud photographs from all regions of the earth were carefully considered, and two years afterwards another edition of the cloud atlas recorded the decision arrived at. The photographer, therefore, who would wish to give a scientific value to his cloud negatives, should obtain prints from them and compare them with the typical pictures in the atlas, and he will find little difficulty in giving to each a correct title. He will quickly note that there are recognised in this atlas a number of compound forms of cloud with such titles as *Cirro-Cumulus*, *Strato-Cumulus*, *Alto-Stratus*, and the like, and that more than one example is given of each kind. It is when we come to consider clouds of the *Nimbus* kind that difficulty is likely to arise, for the *Nimbus* is essentially a rain-bearing cloud, and many other clouds parody it without being of wetting nature. It is therefore as well, in taking photographs of clouds, if we want them for anything besides a pictorial use, to make a note with regard to the weather which prevails at the time. Some of the high clouds, the *Cirrus* type, are so gossamer-like that they are exceedingly difficult to secure without a colour screen. Even in this excellent atlas some of these clouds are represented by drawings, not photographs.

* * *

Telephones and Speaking Tubes.

In a well-arranged studio, where some considerable amount of business is done, arrangements for message sending in various departments are a necessity. The mind travels unconsciously to the telephone when planning such conveniences, so universal is its employment; but there is really no necessity for deeming this the only possible means. In the pre-telephone days "speaking-tubes" were in vogue, the earliest type being simply pipes of gutta-percha. But as even then the substance was costly, in many places of business tubes of tin supplied its place efficiently, till eventually ordinary composition gas-pipe was found as efficient, besides being cheap, convenient, and easily fitted. Some ingenious photographers have adopted in their printing department a reminiscence of school days, when a means of communication from dormitory to dormitory was arranged by knocking the bottom out of a jam jar, putting a string with knotted end through the stretched bladder at the top, doing this with a second jar, and pulling the string taut. A conversation between distant dormitories could be easily carried on by speaking into one jar and listening at the other. Indeed, a company was formed for working a system on similar lines on a large scale, and we know of one large mansion where, at any rate a few years ago only, such an arrangement was in working order. The string was replaced by wire, and the bladder membranes by thin metal diaphragms. We were informed that the apparatus, which, of course, was cheap, was very serviceable, except during stormy weather, most of the wire being carried outside, corners being turned by carrying the taut wire over a species of small wheel, with a grooved, large-toothed edge. According to the "Birmingham Daily Post," however, a new telephonic apparatus has been devised which, we should imagine, will supersede all existing arrangements, and convert telephones and speaking-tubes into museum specimens of antiquity. This is neither more nor less than a "wireless telephone." According to the accounts published, there would be no necessity to raise the voice for long distances, and the

existing instruments would be discarded. Also, a recording photograph can be attached, capable of ready, or even automatic, switching on and off as required. No need for setting up tall poles and apparatus at a great height, and messages can be sent from one house to another without being interrupted by the transmission or reception of any other messages from any other quarter. There are, so far, no actual details published, as the new instrument is not yet patented. We can only wait and wonder what the photographic workrooms of the future will be like!

* * *

Photography in Court.

No one can truly say that photographers as a class are more neglectful of their duties as good citizens than are the members of other professions. But there is one irksome task which, in common with the rest of his Majesty's lieges, they do their best to get excused from. They do not like serving on juries. It is a duty which calls them away from their business for an indefinite time, and often plays havoc with their interests. Moreover, they know well that, for some inscrutable reason, men of leisure are not summoned to serve for years at a stretch, while busy men are called upon at frequent intervals. The fees paid to jurymen, when any are forthcoming, are quite insignificant, and the sole reward is the satisfaction of having fulfilled an unpleasant duty—if satisfaction can be felt in connection with a compulsory performance. But we venture to suggest that if the authorities would permit photographers to take their cameras into court, with full permission to take pictures of judge, leading counsel, and prisoners, they would find that there would not only be a willingness, with a great desire to fill the office of jurymen. And why should a thing which is allowed in Italy be denied to the English? Here is an extract from the "Daily Telegraph" report of the Bonmartini murder trial at Turin:—"When the accused arrived at the court this morning a huge crowd had assembled. Before the opening of the sitting, one of the jurymen focussed a camera on the dock in order to photograph the prisoners when they entered the court." This is all we are told of the photographic arrangements, but we can easily imagine that the jurymen would have an assistant at hand to carry off the plates as fast as they were exposed, so that prints of the prisoners could be on sale outside before the close of the day's proceedings. Of course, such pictures would sell like hot cakes, and the jurymen would be well rewarded for his enterprise. But would this be allowed in one of our London courts of law? We fancy not. The only case we can call to mind in which such a thing was attempted was in the Pigott episode which formed the sensational feature of that famous trial which cost the "Times" so many thousands of pounds. A photograph of Pigott was taken in court *sub rosa*, not by a jurymen, but by one of the court officials, who afterwards showed us the picture. We doubtless had a few friends near him who covered their movements, but the picture was taken, and an unmistakable likeness it was. There is no harm in alluding to the circumstance now, for the photographer has long gone over to the majority. We consider that famous trial, in common with other events of public interest, should be recorded by photography, and although there might be objections to jurymen having their attention diverted from their serious duties by doing the work, an official photographer could be appointed, with authority to use a flash light at the critical moment.

PREPARATION FOR WINTER WORK.

THE Christmas rush will soon be with us, and all professionals should, if they have not already done so, look round and prepare for the work before it comes upon them. It is unfortunate for the worker in the dark and smoky towns that his busiest season comes at what is photographically the worst time of the year. Not only is the operating more difficult, but printing on anything but the gaslight, i.e., bromide papers, takes an annoyingly long time. Nowadays, of course, nearly all town studios have artificial light of some sort for operating, and it is the instruments for producing this that should be looked to, more especially as they are frequently dispensed with during the summer months. Incandescent or any gas systems should have the burners well cleaned and if necessary professionally attended to, the mantles renewed, and the reflectors cleaned. Arc lamps may want the carbons renewing and the feeding arrangement, if automatic, should be regulated. Very much the same remarks apply to magnesium lamps, which should be likewise well overhauled. When translucent diffusing screens are used they will usually pass more light if fresh material is procured, all white stuff, whether fabric or paper, having a tendency to yellow in daylight. The reflecting screen used on the shadow side may also do to be rewhited. Very few places will have their studio lights tissued at this time of the year, but those that do should renew same. Also and most important in smoky cities where the light is least, the skylight should be frequently well cleaned inside and out. The difference in the value of light through a coating of dirt makes it marvellous.

All this is doubtless elementary, but photographers as a class are so apt to let things slide until business becomes pressing that a note now and a reminder may be of service. The printing department will not require much attention. Platinotype and carbon must be well protected from damp, as also unvarnished negatives. Mounted prints should be thoroughly dried before packing. The business portion of the establishment requires attention. It is high time specimens of photographic Christmas cards were got out, and if you have not, the matter should be attended to or the orders for foreign cards, for which photos are most in demand will be lost. In selecting cards pay same attention as to suitability for prints as you would with ordinary mounts. Those with the good old-fashioned mottoes sell best. Midget size seems to be most popular, and if good-sized cards with tasty appearance are chosen, and these are not necessarily expensive, a good price can be charged. Just now you may be thinking of getting new reception room specimens. Some photographers we know do this and make money at the same time. They pick out some of their nicest specimens and also those which are likely to sell, and have enlargements made of them. These are framed up tastefully, the larger sizes in wide oaks and the smaller ones on very large tinted mounts in a narrow band of a frame. A week or two before Christmas these are despatched by passenger train to the original customer for the photograph. A polite note follows, saying: "Mr. So and So has recently made several additions to his show-room pictures, amongst which is the one of Mr. ——. As it is so (beautiful?) he thought you might like to see it with a view to purchase, the price being ——. The print is (say) a carbon on opal, and is absolutely permanent."

Very frequently the pictures are purchased, and after all expenses for enlargements, framing, carriage, both on those forwarded and on return, and packing-case have been paid, it will usually be found that there remains a surplus and several specimens for show. Of course, this system, like the invitation one, can be abused, and doubt-

The Surrey Education Committee, in pursuance of a policy of rewards to encourage regular school attendance, has ordered 100,000 pictorial post-cards of places of historical interest in the county at a total cost of £500.

less is, but in proper hands we do not think there is much objection to it. The patron, instead of ordering from a small photograph, sees the picture before deciding whether or no to purchase.

As before mentioned, Christmas cards should be already shown, so also should any special winter line you make, say, groups at parties, balls, etc., fancy dress portraits, or anything appertaining to the season. We think the once popular pictures with snow worked in might be made into an attraction again. Those who do not remember these may like to know that the effect of falling snow was obtained by taking an old tooth-brush full of liquid colour, holding over film of negative, and knocking sharply. After a little practice it will be found that the film is covered with small opaque dots each separate from the other. The snow on shoulders, hats, shoes, and other parts of attire is put in with a brush by hand. Beside the actual display of photographs, the present is an excellent season for other means of publicity. A tasty folder or booklet dealing either with the studio as a whole or Christmas work especially, should, if sent to the right people, secure full orders.

In conclusion, if, during the dull and somewhat depressing winter months, you feel inclined to let your showrooms and studios get frowsy and dirty, or the specimens bedraggled and faded looking—don't. It is just now, when everything else is murky and cheerless, that the public will appreciate clean and bright rooms and work. Moreover, perhaps, the other fellow is letting things slide; if so, you can get a lead and an honest one, not the poor sneaky methods of price-cutting or personal animosity.

QUESTIONS SUGGESTED BY THE R.P.S. EXHIBITION.

By AN OLD-FASHIONED PROFESSIONAL.

THE Royal Photographic Society's forty-ninth annual exhibition has now been open a month, and has, as usual, attracted a large number of visitors, photographers, and the general public alike, and the opinions expressed on the merits of the work shown have been, on the whole, very favourable. At the same time, I have heard disappointment expressed in some quarters, and this has been chiefly by country professional photographers who have come specially to London to see the exhibition, and learn what are the latest things in the art-science upon which they depend for their livelihood. By many of them disappointment has been freely expressed—that is, from the technical point of view—and this brings us to the question as to whether the R.P.S. has not of late years lent itself too much to the art side to the neglect of purely technical photography?

It will be remembered that a few years ago, when advertising to this subject, Lord Crawford—as President of the Society—made some pertinent remarks on the overlooking of what he tritely termed the “bread and butter” side of photography. He remarked that when he visited places abroad he usually brought away with him a number of photographs of the scenes visited, and those he purchased, as most others did, were clear, sharp, and good photographs of the ordinary type, such as those shown in the shops there, and similar to the views sold here. In expressing these views, Lord Crawford, we venture to say, was simply echoing those of the public generally and those for whom professional photographers cater. Now, the exhibition at the New Gallery contains but few, if any, examples, of that class of work. Pure, unsophisticated photography seems to be conspicuous by its absence. One of the principal objects of the Society, when it was formed some fifty years ago, it may be mentioned, was the advancement of photography both as an art and a science. At one time prints that had hand-work upon

them were not admissible to the Society's exhibitions. In present, as in some previous ones, there are few, if any, that have not been more or less worked upon in one way or other, some to such an extent that little photography is recognisable. Not only are the prints themselves worked upon, but what they are enlargements from smaller negatives, made through the agency of transparencies, the latter, as well as the enlarging negative, has been in many instances most elaborately worked upon by hand, so much so, in some cases, that but little of original photographic base is distinguishable in the finished picture.

Great advances have been made in lenses during the past years, and that they are appreciated by photographers is evidenced by the large sales the instruments have met with at the hands alike of professionals and amateurs; yet the majority of works shown at the New Gallery could just as well have been produced by those of the most primitive type, some, indeed, even with common spectacle lenses. Amongst a certain class of people an idea seems to prevail that if a picture is sharp, and good technically, it cannot be artistic; to be that it must be more or less of the fuzzy order, and in low tones. But what about the works of the late Mr. Vernon Heath, the Messrs. Bedford, father and son, Col. Gale, and a score of others? Were their pictures not technically good as well as sharp photographs, and were they not artistic productions? Are not a very large number of the published portraits of celebrities, and landscapes, produced by the leading photographers, which are technically good photographs, artistic as well? In the exhibition there are some excellent interiors that are exceedingly sharp good photography—are they the less artistic on that account?

Turning again to the “bread and butter” side of the question, would many of the works in the exhibition, if published and shown in the shop-windows, meet with a ready sale, or those the merits of which are so loudly applauded by some? I venture to say that they would not, even if they were issued in a cheap or post-card form. Taking the portraits as shown in the pictorial section (with a few exceptions), would sitters, as a rule, if they had them taken by a professional photographer, and had to pay for them, accept them as portraits of themselves? It would be useless, we know, in the majority of cases for the photographer to try to persuade the sitter they were “art photography.”

Here is another phase of the question that is pertinent, and that there is so much sophistication in the pictures in the present show. It is this. Is there, technically, such good photography done now as there was two or three decades ago when photographers did not rely so much upon retouching to improve the work, as they appear to do at the present time? This is a question that is of considerable interest in connection with the advancement of photography, and it is one that must well be taken into consideration by the R.P.S., which is formed with a view to the advancement of photography. It is true that there is a section devoted to professional work, but what encouragement does it receive? Here a charge is made of wall space, and, as a consequence, there is very little indeed shown except by the manufacturers of material.

It must not be assumed for a moment that I am inclined to decry art in connection with photography—let us have as much of it as possible. But I see no reason why the technical side of it should be entirely lost sight of, and this, some may think, is slowly being the case. Could not one of the rooms in future be devoted exclusively to technical photography—unsophisticated landscapes and portraits—after being approved by committee of selection, composed entirely of technical photographers, without charge for space, and, perhaps, the award of a medal for the best pure photography having artistic merit? Failing this, is not the subject one that the Professional Photographers' Association might well take into consideration. An exhibition in London under its auspices might

and greatly to the improvement of the technical, and "bread and butter," side of photography, and at the same time, perhaps, to its funds.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION AND ASSISTANTS' CERTIFICATES.

Following is the draft of the prospectus of the first part of the scheme of the Professional Photographers' Association for granting certificates of competency to operators, assistants, etc. This is put forward by the Committee of the Association tentatively, with the intention of obtaining the opinions of those interested before finally settling the draft. In our correspondence columns appears a letter inviting criticism, under the signature of Mr. William Grove, hon. secretary to the Association, which should be referred to:—

Pending the maturing of a scheme for holding examinations in practical photography, the Association is prepared to grant certificates to operators, assistants, etc., who can satisfy an examination committee appointed by a Committee of the Association of their competency on the testimony of their past and present employers.

Certificates will be granted solely on the grounds of photographic ability, and will take no cognisance of personal character.

The right is reserved of requiring such examination as can conveniently be arranged in addition to employers' testimony of ability, and also of calling for specimens of applicants' work. Candidates for certificates for retouching, and those who wish retouching to be included in their qualifications, will be required to furnish specimens of their work upon negatives supplied by the Association, performed under prescribed conditions. Application for a certificate must be made upon a form to be obtained from the hon. secretary of the Association, furnishing full particulars of the applicant's employments, their duration, etc.

Enquiry of the applicant's present and previous employers as to the capabilities of the applicant will be made from the office of the Association. A form will be used, and ordinary testimonials or references will not be accepted except when a previous employer is dead or not to be reached. All information given to the Association in reference to the granting of certificates, whether from applicants or those giving references, will be treated as strictly confidential.

Certificates will be general or special.

General certificates will be granted to operators and assistants in three grades, and will be for competency in studio routine and the ordinary work of portrait photography, not including retouching. General certificates will be granted to printers in three grades, and will be for competency in the work appertaining to the printing-room.

Special certificates will be given for aptitude in branches of photography not included in the general certificates, such as enlarging, retouching, landscape and architectural photography, etc.

As, when arrangements have been made for granting certificates upon personal examination, an examination fee will have to be charged, and, as it is not intended that candidates for certificates upon the testimony of the employers shall be more advantageously treated than those who shall submit themselves for examination, the following fees have been tentatively fixed:—For first grade, £2; for second grade, £1 10s.; for third grade, £1. Fees are payable with the application.

No certificate of the first and second grades will be granted to anyone under twenty-one years of age. In the third grade, under twenty years of age.

No reference will be accepted for service of less than six months.

For a third-grade certificate candidates must have had at

least three years' experience of which they can give an account, and must be able to refer to employers as to their photographic abilities during service extending over two years.

For a second-grade certificate candidates must have had at least five years' experience of which they can give an account, and must be able to refer to employers as to their photographic abilities during service extending over four years.

For a first-grade certificate candidates must have had at least eight years' experience of which they can give an account, and must be able to refer to employers as to their photographic abilities during service extending over six years.

GENERAL CERTIFICATES.—OPERATORS AND ASSISTANTS.

Third Grade.—Assistant's Certificate.—The candidate should be able to take charge of the camera when acting as studio assistant, must be competent at developing, fixing, and washing plates, and bromides and gaslight papers, must be able to fill slides, back plates, prepare and pack up requisites for an outdoor job, and generally carry out directions with regard to ordinary photographic work not requiring photographic experience and skill. He should be acquainted with the ordinary routine of a photographic business, and be able to make rough proofs in P.O.P. or albumen.

Second Grade.—Operator's Certificate.—In addition to the qualifications entitling him to a third-grade certificate, the candidate must have a general knowledge of studio work, and be able to pose and light the sitter, and act in the absence of the principal. He should be able to take groups outdoor and home portraits, be expert at copying, and have a general knowledge of the requirements of landscape and architectural photography. He must be able to perform all the chemical operations that may be required in ordinary photography, including the mixing of solutions and the reduction and intensification of negatives. He must be able to varnish negatives and prepare them for the retoucher or printer. He must have a general knowledge of printing processes, also of enlarging, and of the special qualities of negatives desirable for various applications.

First Grade.—Principal Operator's Certificate.—In addition to possessing the qualifications entitling him to a second-grade certificate, the candidate must prove his ability to take entire charge of the studio of a high-class establishment. He should be competent in electric and other modes of artificial lighting, must furnish evidence of taste and artistic feeling in posing, lighting, the use of accessories, and also in the mounting, framing, and general get-up of prints.

GENERAL CERTIFICATES.—PRINTERS.

Third Grade.—The candidate must be able to attend to a reasonable number of printing frames with printing-out papers. He should be able to print by actinometer under supervision. He must be able to fill and refill frames, and be acquainted with a system of keeping register of the number of prints made. He must be able to tone, fix, and wash P.O.P. or albumen prints.

Second Grade.—In addition to possessing the qualifications entitling him to a third-grade certificate, the candidate should be able to print in bromide and gaslight paper, and must be able to print either in carbon or platinotype. He must be able to mask negatives to vignette accurately, and to prepare and keep in order baths and other solutions used in his department, and also to trim and mount prints.

First Grade.—In addition to the qualifications entitling him to a second-grade certificate, the candidate must be able to organise and take entire charge of the printing department of a high-class business. He must be acquainted with the working of all ordinary printing processes, and be able to print in clouds, and backgrounds, and be an adept at simple combination printing. He must also be able to improve the results from defective negatives by tinting, shading, or other means, and generally must display artistic feeling in dealing with the work of his department.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Operator's and Assistant's Certificates.—Form of Application.

To the Honorary Secretary of the Professional Photographers' Association.

Sir,—In accordance with the published regulations, I beg to apply for a certificate, and declare that the particulars herein-after given as to myself and my photographic service are true.

I enclose fee.—Yours faithfully,

Signature.

Present address.

Full name.

Age last birthday.

Grade and description of certificate applied for.

Present employer's name and address.

Date of entering present employment.

Particulars of class of work engaged in.

Previous employers (give dates of entering and leaving their employment, and state kind of work principally engaged in).
Give full particulars, using the back of the paper if necessary.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Information given to the

Association will be treated
as strictly confidential.

51, Baker Street, W.

..... 19...

Dear Sir,—Under the regulations of the Association for granting certificates to photographic assistants, upon the testimony of their present and former employers, a copy of which is enclosed, Mr. has made application for a certificate of the grade, and states that he was in your employment from to

The President and Committee will feel obliged if you will kindly supply the specific information required by replying to the questions left open on the enclosed form. The certificates of the Association take no cognisance of personal character, but are granted solely for photographic ability and proficiency in the business of a photographer.

A stamped addressed envelope is enclosed for the return of the form.—Yours faithfully,

HON. SECRETARY.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Operator's and Assistants' Certificates.

To

Mr., of, having applied to the Association for a grade certificate, states that he has been in the employment of your firm, and that you are able to testify to his abilities in photography. A succinct reply to the questions is requested, and, at the conclusion, any general comments concerning the photographic qualifications of the applicant will be welcomed.

General.

How long was applicant in your employ?

(Gives dates from and to if possible.)

What position did he occupy?

Was he orderly, clean, and careful in his work?

Did you find his work satisfactory?

Third Grade.

Is he competent to develop plates?

" " develop bromide and gaslight papers?

" " back plates?

" " make rough prints in P.O.P. or albumen?

Has he assisted in the studio?

Can he adjust the camera?

Can he mount and finish prints?

Can he make good copies of photographs under supervision?

Second Grade.

Has he a general knowledge of studio work?

Can he take entire charge of the camera when acting as assistant to the principal?

Did you find his posing and lighting satisfactory?

Is he successful in the management of his sitter?

Can he satisfactorily manage groups
indoor?
outdoor?

Has he a general knowledge of the requirements of landscape and architectural photography?

Can he make good copies of old photographs and other difficult subjects?

Has he a general knowledge of printing processes?

Has he a general knowledge of making enlarged and reduced negatives?

Can he prepare developing and other solutions accurately?

Can he intensify and reduce negatives?

Can he varnish negatives?

Has he a good general knowledge of the ordinary routine of photographic business?

First Grade.

Has applicant been accustomed to have entire charge of your studio?

Is he successful in electric and other modes of artificial lighting?

Is he of good address and tactful with his sitters?

Do you consider he possesses artistic feeling in posing, lighting, and the use of accessories?

Also in the mounting and general get-up of prints?

Has he a fair knowledge of the optics and chemistry of photography?

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

General Certificate.—Printers.

How long was applicant in your employment?

(Give dates from and to if possible.)

Was he clean and careful in his work?

Did you find his work satisfactory?

Third Grade.

Can he attend to a reasonable number of frames?

Can he print by actinometer under supervision?

Is he able to fill frames and keep register of prints made?

Can he tone, fix, and wash P.O.P.?

Can he tone, fix, and wash albumen.

Second Grade.

Can applicant print in platinotype?

" " " carbon?

" " " bromide?

" " " gaslight?

Is he a good vignetter?

Can he sensitise albumenised paper?

Can he keep the silver bath in good working order?

Can he make toning baths and other solutions?

Can he trim and mount?

First Grade.

Can he organise a printing department?

Can he control under-printers and assistants?

Can he print in skies to landscapes, and do other combination printing?

Does he thoroughly understand all the ordinary printing processes?

Is he able to improve the results of defective negatives tinting, shading, and other means?

Is he possessed of artistic feeling in the work of his department?

Has he any knowledge of chemistry?

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Retoucher's Certificate.

General Questions as for Printers.

Do you consider him a good retoucher?

What was the largest size heads he was accustomed to retouch?

Is he good at large heads (three inches or over)?

Can he successfully make alterations with the knife?

Is he good at reducing high lights and halation?
 Is he good at strengthening under-exposed parts of negatives?
 How many negatives can he do in a day of eight hours (say, heads of one inch from chin to forehead)?
 Has he a knowledge of drawing?

SELECTIONS.

NOTEWORTHY OPINIONS CONCERNING ART AND PHOTOGRAPHY.

[Translated from the "Photographische Correspondenz."]

FRANZ VON LENBACH expresses himself in the following terms with reference to the study of the old masters:—

"Only by studying the old masters can one succeed in understanding what art must really be.

"Beauty was the aim of the art of the old masters, truth is the rallying-cry of the moderns. But the beautiful is always true, when it is bound to us organically by the legitimate process of its creation. Yet what is true is far from beautiful, as Piloty was careful to teach.

"If a thing is harmonious its effect is tranquil; but it is this that some of our youths strive against, who are full of nerves, excitable, and long for sensation. The mad juxtaposition of baroque ideas, glaring colours, and distorted forms, the audacious representation of the hateful and shameless causes an outcry, and an outcry it is intended to excite.

"These rude, vehement efforts separate the moderns from the old masters, those sensitive representatives of art.

"The crude and the violent have always attracted the multitude more than the purely beautiful.

"If we cross a street, for example, and a cab is driven straight at a child, the wheel passing over it, and cutting it in two, we and everybody else would run to it, and our minds would be so full of the frightful sight that the Venus de' Medici, the Venus of Milo, and Pallas Athene might pass by, and we should scarcely observe them.

"Upon this trait in human nature some artists at all times have reckoned, who wished to surprise, dazzle, and excite, instead of quietly blessing mankind. But the great masters of former times draw one so gently and sweetly within their circle.

"The object of their art was the representation of Nature as they saw it with a harmonising mind."

THE FALSE EDUCATION OF TASTE.*—Photographers are an inexhaustible theme. The obliteration of their work will continue to remain the artist's Utopia. Yet it should be unnecessary, for photography may be art in the purest sense of the word, as the exhibitions by amateurs within recent years have shown. Even the work of professional photographers may show some trace of art.

With this object in view it is quite possible to imagine a high school for photographers. First-rate portrait-painters would be the instructors, for everything may be had for money. Psychological, æsthetic teaching would lead the scholars to understand a little of human physiognomy, to find what is characteristic, and to discover the pose in which it may be most truly expressed. Also a collection of copies of good modern portraits should be available for study; learned men, merchants, officers, and actors, slim girls fresh from school, and stout butcher-wives. The scholars would see that even the most commonplace subjects may be translated into art, and that the work of the portrait-painter in carrying out his subject does not consist of retouching. By turning over the leaves of his book of specimens he would find guidance for the pose and arrangement of his work, and by comparing it with similar portraits by artists he would become aware of the points in which it was most wanting in taste.

But what are the facts? The reception room at once shows that the industrial art movement of the last ten years has

passed by the photographer without any effect whatever. This would be of no consequence if fashion alone were concerned. But industrial art of the present day formulates a new principle. We are honest people. Take us as we are, and let us denounce as swindlers those who deceive us with high-sounding names. We should therefore demand honesty from the industrial arts. No false splendour should cover our inward hollowness. Everything must be what it proclaims itself. Purpose and material alone must determine its form. We are at last also awakened to the consciousness of class. We find it paltry now to decorate our rooms with plaster and papier-mâché, in imitation of the marble and bronze used for the decoration of king's palaces. The king is honoured by his dignity; the work of our hands should honour us. Our industrial art is evidence of this democratic pride.

Only at the photographer's do we find a parade of the columns, railings, balustrades, and swinging-doors, by which in early days banker's wives were given in their pictures the appearance of Van Dyck princesses. Here we see toppling tables, rickety stands, and elaborately-turned chairs. The miserable lumber not only stands there, but represents artistic accessories. It gives tone. The fat butcher's wife steps on to the balustrade and plays the part of Juliet spying for Romeo. The learned man sits, possibly straddles, the tilting-chair, before the what-not, and keeps still when the photographer places in his hand as insignia of his calling as investigator Meyer's Encyclopædia or Redwitz's "Amarant."

The most earnest people, when at the photographer's, appear as though possessed of the devil. Educated, as they are, in the history of art, they remember Millet's words: "The beautiful lies in the harmony of man with his work" and they find the truth of this confirmed in life. The peasant, who, in his jacket in the field, looked as dignified as a king, and the porter, who, in his blue blouse, was like a primeval giant, come out ridiculous and awkward, as though taking a walk on Sunday afternoon. The hat grows into a chimney-pot, the unaccustomed clothes confine him, and he loses his natural freedom and its character—that grand rhythm given by labour to his body. The waitress, who looks so smart and neat in her white apron, with a tankard in her hand, exposes her admirer to ridicule when she appears bedizened as a caricature of a lady "Unter den Linden." The educated man knows all this. Nevertheless, he puts himself in holiday humour when he goes to the photographer's. He uses the curry-comb, curls his moustache, permits a fur which does not belong to him to be thrown pictorially over his shoulder, and looks inspired, as though he were the recipient of a revelation. Finally, whatever remains of the character of the individual is effaced by retouching.

Everybody has some share of character. Life is the pencil which has drawn us. The skull is the receptacle of the thoughts which dwell behind the forehead. Every woman, every young girl, is beautiful, because in this world she exists but once, and resembles no other, even her twin-sister, from whom she differs in fine gradations. At the photographer's everyone poses the same, adopting one of the three attitudes which the catechism of photographic rules prescribes (?). The wrinkles are smoothed out, the missing hair supplied, and the snub nose straightened. The eye has lost its expression, the forehead its shape, and the face of the simple schoolgirl its freshness and charm. The head of the man has grown into a hairdresser's model, and the girl into a doll.

This appears to be of very little moment. But serious consequences are involved. According to Schiller, evil acts continue to bear evil. Such parodies, stripped of individuality, do not appear coarse to the photographer. On the contrary, he feels flattered by such a picture, sets it upon a walnut stand, or hangs it upon the wall in a plush frame and looks at it every day with satisfaction. Truly, it is not decorative—it

* Fragment of an essay. R. Muther, "Studies and Criticisms." Wiener Verlag.

should be "in oils." The empty, expressionless "cabinet" must be raised in power and become the emptiest, the most expressionless. It must go to an art institute to be enlarged and daubed with oil colour. Many think they would like to have their portraits painted. And then, woe to the artist! Begin how he will, the photograph was more beautiful. The martyrdom of our portrait-painters is owing to retouched photographs.

PROFESSOR RICH. MÜTHER.

[Fortunately, the conditions which are here depicted belong to the ocean of "tempi passati," and it has long been acknowledged—at least, theoretically—by all educated photographers, that the retention of characteristic form is a leading fundamental principle.—Ed. of "P. C."]

DR. KOENIG'S COLOUR PROCESS.

[Supplementary to what has already appeared on this subject, we are indebted to Mr. Jules Fuerst for the following translation of the lecture delivered by Dr. E. Koenig before the German Naturalists' Congress, Breslau, on the 21st September, 1904.]

WHILE the Leuko bases of some classes of organic colouring matter, i.e., of Safranines are so unstable that it is not possible to isolate them, others like the Leuko Malachite Green are, as is well known, easily prepared in a pure state, and are comparatively constant when exposed to air. Many chemists have probably observed that these most constant Leuko bases when kept for a long time, will colour strongly only when exposed to light. Careful researches about the light-sensitiveness of the Leuko bases have only been made by Gros, in Ostwald's Laboratory, who examined especially the Leuko compounds of fluorescein and its substitutes. He found that Leuko compounds, roughly prepared are nearly all more or less sensitive to light and measured the oxygen absorbed on exposure to light of the water solutions of Leuko bases, i.e., their salts.

Nobody else seems to have worked in this direction or to have thought of using the Leuko bases for making photographic images.

Before I start on my subject I will touch in a few words on a purely photographic subject. I presume the principle of three colour photography, as known, viz., of the object to be photographed three part-negatives are made, of which one, when copying, renders only the blue, the second, the red, and the third, the yellow parts of the object. The production of such negatives is comparatively simple, and the principal reason why three colour photography (which for the graphic industries is of greatest importance) has not yet found use in photographic practice is on account of want of a suitable copying process. I will not detain you by enumerating the various copying processes, but would only say shortly that all methods used hitherto base on the light sensitiveness of gelatine saturated with bi-chromates, be it by copying on to coloured pigment paper, or be it by colouring colourless gelatine images with organic colours. The three monochromatic part-negatives which have been got by one of the methods mentioned, are joined into one image, which then renders all the colour shades of the original. Undoubtedly in this way very nice three-colour images can be obtained, but their production is so difficult that only a few people can produce acceptable coloured paper images. Not the smallest disadvantage of the old methods is the impossibility to follow the progress of the copying process ocularly.

An ideal copying process for three colour photography would undoubtedly be one where neither colouring takes place, nor where copies are made on coloured paper, but which works only with colourless layers which when exposed to light will, according to their previous preparation, colour directly yellow, red, or blue.

To find such a process we in the Photo-Chemical Laboratory of the Farbwerke Meister, Lucius and Bruning, Hoechst a/M, carefully examined into the most different Leuko bases, but soon began to see that the Leuko bases by themselves on exposure to light are not capable of giving sufficiently vigorous and brilliant images. We then supported the Leuko bases by a layer of acetylhydrocellulose, or gelatine, but our hope to obtain thus more vigorous images was not realised.

Only when we chose collodion, as image carrier, we suddenly observed a marvellous step forward in light sensitiveness. Leuko bases which were exposed to light for hours by themselves, gave only a faint coloration, but were vigorously oxydised in presence of collodion in a short time. Other Leuko bases which for themselves were so light

sensitive that on fairly long exposure under a negative they gave distinct, although weak and photographically useless image, colour in the collodion film rapidly and intensively.

We soon concluded here that collodion could not act as a mere image carrier, and, in fact, it soon showed itself that the Leuko bases were oxydised on exposure to light at the expense of the nitric acid groups of nitrocellulose. We then examined a great many other bodies and found that, similar to nitrocellulose, all nitric acid esters, especially those of the higher alcohols re-acted. On the other hand the nitric acid esters and isomeric nitro compounds of the aliphatic and aromatic series are ineffective. The nitrosamines show similar, although weaker, effects than the nitric acid esters.

It is interesting to know that the light sensitiveness of mixture nitrocellulose and Leuko bases can be diminished considerably by addition of urea or antipyrin. This observation seems to point to the fact that the Leuko bodies are actually oxydised by No or No₂ groups which dissociate out of the collodion.

Addition of turpentine or aniseed oil, which are looked upon as oxygen carriers, do not or hardly accelerate the production of Leuko images. But when we once added to the solution of Leuko bodies in collodion various organic bases with the intention of preventing small air oxydation occurring in some Leuko bodies, we observed with astonishment the films (layers) containing chinolin and its homologues, increased again extraordinarily in their light sensitiveness. An explanation of this curious phenomenon cannot be given. It is very remarkable that more vigorous pictures should be obtained with chinolin bases than without, because it should be expected that the addition of a strong base would rather prevent the formation of colouring matter, as it is well known that the salts only of the colouring bases are coloured. In this picture you see clearly the influence of chinolin which, moreover, is principally effective with the Leuko bases of the blue and green triphenylmethan colours.

Nitrocellulose is not by any means the most effective of the above mentioned compounds, but is only specially suitable for the production of pictures because it produces at the same time the layer (film) that is destined to carry the pictures. Still more sensitive to light are the mixtures of Leuko bases with the nitric acid esters of glycerine, glucose, and mannite.

For instance, if a piece of blotting paper be saturated with ether solution, say of Leuko malachite green or Leuko flavanilin, barely colours with a short exposure, but if some nitromannite be added to the solution the paper exposed to light colours intensely and rapidly. The light-sensitiveness of mixtures of Leuko bases with nitrocellulose can be increased quite extraordinarily by the addition of nitromannite. You see here two pictures, of which one is much more vigorous than the other. The exposure in both was twenty seconds. The light sensitive film consisted of nitro-cellulose, Leukosetocyanin (o-Chlorotetraethylamidodiphenylmethan), and chinolin. To film for the first picture a small quantity of nitromannite was added.

I would repeatedly observe that it is quite impossible to produce approximately useful photographic images with Leuko bases alone, with Leuko bases which are carried by indifferent films. Copies result always flat and without vigour, the oxydation of the Leuko bases in light through the oxygen in the air seems soon to react maximum long before the entire quantity of the Leuko bases is oxydised.

Also bodies which are not so-called Leuko bases in the ordinary sense are oxydised by the light into colours in the presence of repeatedly named nitric acid esters, as, for instance, p-amidodiphenylamin. This base is known to be much used in carbon printing for oxydation black, and gives when mixed with collodion or similar bodies and coated on paper strongly coloured pictures, when exposed to light in a very short time.

Blue images can be made by means of o-Chlorotetraethylamidodiphenylmethan, green images with Leukomalachite green, violet images with m-nitro or m-amidotetraethylamidodiphenylmethan, red images with p-Leukoaminin or Leukohodamines, violet images with Hexaethylparaleukanilin, yellow images with Leukofluorescein and Leuko flavanilin.

The fixing of the images gave great difficulty to begin with. Since Leuko bases can be dissociated from the collodion film with benzene, toluol, ether, or chloroform, but such means of fixing are not used in practice. The nearest fixing mediums were diluted mineral acids, which nearly all Leuko bases are easily dissolved. Nevertheless, images could not be so fixed because the Leuko bases as well as collodion

show a certain tenacity to nitrocellulose and kept very fast under certain circumstances. Better result was obtained in fixing with diluted organic acids, and finally it was found that the monochloroacetic acid was the best fixing medium for nearly all Leuko bases; acetic acid, di- and tri-chloroacetic acid cannot be used.

Gros has already examined the behaviour of Leuko bases against multicoloured light, and "roughly," as he says, he found that with most Leuko bases a maximum appears when illuminated with complementary coloured light. Gros obtained with all Leuko bases the weakest effect under red glass, the strongest under "pink" ("Rosa"). We exposed the various sensitive films under colour filters, as used for the additive process of three-colour photography, and it was found that the exposed strips produce under the complementary coloured filter a maximum, and under equally coloured a minimum of intensity. Thus, blue, green, and violet is coloured strongly under red and yellow but scarcely under blue, whereas red under green and yellow filter is coloured very strongly, under blue little, and under red not at all. Finally, yellow under blue is coloured very strongly but scarcely under yellow. For information, we show here a strip of collodion paper which naturally shows the strongest black coloration under blue.

The strong action of the so-called nonactinic red on the blue and green light-sensitive films is very interesting.

Ostwald has already shown that the action of light on photographic preparations is not a peculiar one, that light really only accelerates effects which take place themselves after a considerable time even when light is excluded. Thus, as is well known, photographic plates and papers are decomposed when kept for a long time even in the dark, and especially rapidly the light-sensitive gelatine when mixed with bichromate. With our new light-sensitive films it is the same thing. The effect produced by light in a few seconds or minutes takes place in the dark after hours, days, or weeks, as the case may be, and the most light-sensitive films are also in the dark the least permanent, so that they must always be prepared only shortly before use. I wish, however, to observe that even when kept a long time in the dark the films are never coloured so deeply as they do in a short time on exposure to light.

The application of these observations for three-colour photography is therefore to be summed up in the following manner:—A piece of paper is coated with blue collodion and exposed to light under the corresponding part-negative. When it appears sufficiently vigorous it is fixed in a 10 per cent. solution of chloroacetic acid, washed and coated with a thin hardened gelatine film, and then dried. The gelatine film serves to protect the first collodion film from dissolution when coating the second. The dry blue image is then coated with red collodion and the corresponding part-negative is placed in such a manner that the contours of the negative register exactly with those of the blue image. Again, expose to light, fix, wash, and produce finally in quite the same manner the yellow image. On account of the perfect transparency of the extremely thin films and on account of the brilliancy of the colours used the copies appear very uniform, and the shaded colours especially show with great effect. The quantity of Leuko base, as used, is very small, in consequence of the enormous expansiveness of triphenylmethan dyes, so that a picture made in three layers is no more expensive than an ordinary gelatine or pigment print.

The light permanency of the pictures is, of course, not absolute, though relatively fast colours are used for making the part-pictures. The least fast is the blue, which, however, exceeds in permanency the so-called cyanotype (iron-blue prints). Considering the difficulties encountered up till now when copying from three-colour negatives the new direct copying process of the Hoechst *Farwerke* to be known as "Pinachromy" may be chronicled as an extraordinary improvement. As is well known, coloured diapositives have been easily made, but three-colour photography could not become popular so long as it was not possible to produce in a simple way white paper pictures (positives). This, we believe, our copying process affords, even for the mere amateur, and will, we hope, contribute to give new life to the somewhat stale interest in photography.

INSTRUCTIONS FOR "PINACHROMY," FOR PRODUCING COLOURED PHOTOGRAPHS (POSITIVES).

This copying process, based on the oxydation into colours by exposure to light, of colourless Leuko bases in the presence of certain substances like collodion or other nitric acid esters.

The main substance for all three preparations is a

1.5 per cent. collodion, made, for instance, by mixing
1 litre of a 3 per cent. commercial raw collodion with
500 c. cm. alcohol, and
500 c. cm. ether.

When using 2 per cent. commercial collodion mixed with

500 c. cm. 2 per cent. collodion.
85 c. cm. alcohol, and
85 c. cm. ether

The three part-negatives must not be weak or flat, but must be of good density and very clear.

Copying in direct sunlight gives specially brilliant pictures.

As a basis for the picture it is best to choose a white matte or brilliant Baryta paper, not too thickly coated. Many papers, especially those with a very strong layer of baryta, have the property that they are put out of shape by the various manipulations, and such papers are naturally useless as they prevent the images being correctly registered.

The black bottles contain the Leuko solutions.

The white bottles contain the necessary additions.

The bottles for blue, and additions for blue, are round.

The bottles for red, and additions for red, are square.

The bottles for yellow, and additions for yellow, are octagon shape.

(A weak colouring of the colour solution mixed with collodion has no importance for the success of the picture.)

For use, take:—

50 c. cm. collodion 1.5 per cent.,
5 c. cm. Leuko solution, and
5 c. cm. of the particular additional solution.

Mix same in a dark room lighted by artificial light. Make only sufficient for what is required during the same day.

It must be observed that the blue collodion is not sensitive to dark blue, very sensitive to red, yellow, and green light. The red collodion, on the other hand, is not sensitive to red light, little sensitive to dark blue, and very sensitive to green and yellow light. The yellow collodion in general is only sensitive to blue light.

I. PRODUCTION OF THE BLUE PRINTS.

Commence making the blue print by taking a piece of paper which is from 1.2 cm. larger than is required for the negative, and pour the blue collodion over it. The simplest plan is to turn up the edges of the paper about 5 mm. high, fix the paper with four pins on a piece of wood, pour the full quantity of collodion over it and drain under a continual rocking the remainder back into the bottle. Collodion which has already been used may be used again by the further addition of some alcohol and ether.

The preparation of the paper is made in a very weak artificial light.

To make a layer, 10 by 13 cm. size ($\frac{1}{2}$ -plate size), about 1.5 c. cm. collodion is used.

After the paper has been dried it is exposed under the red filter negative to daylight. When looking at the copy it is necessary to be very careful on account of the enormous light-sensitiveness of the paper.

The copying can be done very quickly, and with clear negatives and bright sunlight, 20-40 seconds are sufficient. It is recommended not to print the blue picture too deeply; with some experience one soon obtains the proper degree. The image is then fixed in the dark in 15 c. cm. fixing acid and 85 c. cm. water, and it is recommended to add to the fixing bath about 1 c. cm. of a 10 per cent. solution of sulphite of sodium. The bath, in consequence, remains clear for a longer time and can be used for fixing from 5 to 6 copies, 9 by 12 cm. ($\frac{1}{4}$ plate) size. After fixing, wash for five or ten minutes, and dip the copy into the following chrome-gelatine solution:—

3 grammes gelatine,
200 c. cm. water,

0.6 gramme chrome alum (it is best to use basic chrome alum).

This solution must be made up fresh every day.

To dry, use clips for hanging up the copy. Then again dip into the chrome-gelatine solution. When hanging up, it must be observed, the edge of the copy (which was in the first instance on top) must now be hung downwards.

II. PRODUCTION OF THE RED PRINTS.

The dried copy, prepared with chrome gelatine, is now covered with red collodion in a light red light, and is dried in the dark.

Cover the blue print with the green filter negative in such a manner that there is a perfect register. This work can be done by diffused daylight. Print until the red appears sufficiently vigorous* and fix for five minutes in the following solution:—

15 c. cm. fixing acid,
85 c. cm. water.

The addition of sulphite is detrimental here.

The copy must be kept actively moving in the fixing bath. This bath is used only once. It is recommended, when printing, to cover the projecting edges of the print with small strips of paper in order to protect them from the light.

The fixed print is washed for about five to ten minutes in the same way as the blue print, and covered twice with chrome gelatine.

III. PRODUCTION OF THE YELLOW PRINT.

Pour over the dried blue-red print the yellow collodion in light-red daylight, or white artificial light, and expose to light under the blue filter negative.

Fix for five minutes in the following:—

15 c. cm. fixing acid,
85 c. cm. water,
5 c. cm. sulphocyanide of ammonia, 1.5,
1 c. cm. sulphite solution, 1.10.

After fixing, the image is washed for five or ten minutes in distilled, or rain, water, and is again dipped into the chrome gelatine and then dried.

To protect the complete print against mechanical damage, it is best to cover it with a positive varnish.

We draw the attention of users to the fact that the concentrated fixing acid is very caustic, and that sensitive skins are irritated by the diluted fixing baths.

ROYAL PHOTOGRAPHIC SOCIETY EXHIBITION.

TECHNICAL AND SCIENTIFIC EXHIBITS.

THE section devoted to scientific and technical photography and its application to processes of reproduction contains a good number of what may be regarded as instructive exhibits, many of a merely interesting character and only a few that one would wish elsewhere. As was to be expected immediately after last year, when this section was devoted entirely to invitation work, from some points of view the technical section is not all that it should be. The break in the continuity of the section as a competitive one, dependent upon the voluntary entry of exhibits, makes itself felt, the effect being shown in the fewer exhibits and the non-representation of many phases of applied photography. There are many reasons which can account for a much greater shrinkage, however, than that shown in this year's exhibition. Photography undoubtedly attains its greatest and most lasting value, say what one may about its artistic aspect, as an impartial and exact recording agent, and there are more great men in science who recognise its unassailable position in that sense than those in the fine arts who admit its claim to rank as a means of artistic expression. On the other hand, it has to be admitted that few of these scientific men have any regard for photography for its own sake. They apply it to astronomical research, the microscope, surveying, and an endless list of purposes, but each centres his interest in the study in which he is engaged, not in photography, which makes it possible for him to achieve his ends. It is not so much the photograph of which the photomicroscopist is proud as the wonderful record of the subject he is examining. Firstly a microscopist, he is only secondly a photographer, and one must not wonder at his preference to show his results to his microscopical friends rather than to his brother photographers. This fact is certainly at the bottom of the want of character seen in most of the technical exhibitions we have had. In the pictorial side of photography, the photograph and the maintenance of its author's reputation as a photographer are everything, but in the direction of applied photography it is the subject to which it is applied that benefits. There is no cause for wonder, therefore, that the scientist who has successfully applied photography to his work so often fails

to be interested in a merely photographic show, and one should be encouraged rather than depressed by the fact that the section this year includes what it does, incomplete though it be.

Two medals have been given by the judges in this section, one to Mr. A. C. Banfield, and the other to Mr. C. Thurston Holland.

Mr. Banfield receives the medal for a series of thirty-two prints illustrating in a strictly comparative manner the successive motion of a cat and dog jumping an obstacle one foot high. There are sixteen pairs of photographs taken at approximately equal intervals, and they illustrate in a very convincing manner, as the catalogue points out, the ability of the animals to judge the amount of effort necessary to carry them clear of the obstruction. The prints show very clearly how the creatures take the ground and how their subsequent movement are ordered. The series is a clever supplement to the photographs of splashes shown in this section last year by the same exhibitor, and their recognition by the judges will be generously endorsed.

Mr. C. Thurston Holland gains the society's medal for a series of radiographs which are exceptionally fine. There are eighteen prints all of a pathological nature. We were most struck by the print of a malignant growth in the fibula, of myeloid sarcoma, which shows very clearly the growth within and expanding the bone. This was afterwards verified by operation. Next in importance is a print showing exostosis of the tibia, growing from a broad base and almost entirely composed of bone. Others which appealed to us show acute tubercular disease of tibia and fibula, and acute suppurative inflammation of the osium and periostium (the thin, delicate membrane forming the immediate covering of bones) of the tibia. Mr. Holland is to be congratulated on his excellent exhibits, which well deserve the distinction it has achieved.

The application of photography to the microscopic examination of metals is admirably shown in Dr. Carpenter's series of photomicrographs. One is enabled to distinguish with ease the change of structure in a boiler plate brought about by shearing. The breaking up of the two structural constituents of mild steel by rolling, the structure of welded mild steel plates, with satisfactory and unsatisfactory welds, and the structures of sound and faulty bronzes are also well rendered. The magnifications are principally 150 diameters.

Mr. Arthur E. Smith exhibits a number of fine photomicrographs of which the vertical section of the human tongue, showing fungiform papillae (x 175), is undoubtedly the best. We do not remember having seen a finer illustration of this subject in any medical text book. The section of human skin, by Mr. T. C. Hughes, showing sweat gland and duct, is also good, but the definition is not so fine as in the former. In another branch Mr. Smith's print of the eggs of housefly (x 72), is good, while for extreme definition his stem section, *Aristolochia Gigas* (x 50), can hardly be beaten. Mr. Walter Plover Young has four photomicrographs of botanical specimens, the most interesting being the single hair of the stinging nettle, showing the cutting edge still protected by terminal knot. Mr. Edgar Senior is represented by two photomicrographs, among them being one of the tongue of a butterfly (x 77). Other photomicrographs of a good order are the low power work by Mr. J. I. Pigg, who shows the stag beetle, hawkmoth and leaf insect.

Process work is represented by some examples of the student's work at the London County Council School of Photo-engraving, at Bow Court, including photolithographs, collotypes, and tri-colour impressions. Other exhibits coming under this head are the "Colourtype" reproductions from paintings by Carl Hentschel, and some of the work reproduced by Messrs. John Swain and Son. The Art Reproduction Company have a few frames of photogravures of very good quality, one being coloured after the method previously seen in this firm's work, and with considerable success.

Mr. F. W. Plews has on view a number of examples of photo-algraphy in three and more colours, made in an endeavour to introduce three colour work into lithography.

It is convenient here to mention the latest results by Mr. J. Horn Player, with his process of copying by passing light through the sensitive paper on to the print or design to be copied. The process has been described several times, and is now well known, but some new material will be found in the two copies of engravings printed on bromide paper by a luminous negative (excited to fuller action by heat), obtained by allowing yellow light to pass through an isolated phosphorescent surface on to the picture copied, the two being in close contact.

The Astronomer Royal sends ten photographs, which will bring hom

* The red collodion copies take a longer time to copy than the blue collodion.

to many who have not grasped it the magnitude of the task which observatories throughout the world have entered upon. They are specimens of the Greenwich section of the international photographic chart of the heavens, which will require as many as eleven thousand plates before completion can be announced. The work is being performed in duplicate, the second series being so taken that the central portions of the plates of the first series are near the edges in the second series.

Of natural history photographs there are several, the best amongst them being the small collection contributed by the Zoological Photographic Club. Mr. Douglas English helps the success of this department of the exhibition by his pictures of the polecat, the stoat, marten, shrew, weazels, and other creatures in characteristic attitudes; while his fellow-contributors, Messrs. R. Fortune, H. Lea, J. Atkinson, and W. Y. Sainsbury, also deserve high commendation for their work.

A clever photograph is that of a flying seagull, taken by Mr. B. H. Bentley, at sea. He tells us that the exposure was 1-500 second, at $\frac{1}{4}$, a reflex focussing arrangement being used in combination with a telescopic eyepiece to obtain a maximum of sharpness. The print is enlarged six diameters. Mr. R. A. Malby shows close by a set of prints illustrating the feathering of a thrush, the bird's side, breast, inner and outer sides of wing, feet, and legs being depicted. Miss E. Turner has succeeded in photographing a short-eared owl, enjoying a sun bath. As a record of a somewhat curious proceeding, the photograph is not without its interest.

Captain F. D. S. Fayer's photographs of the Daboia are somewhat unique, showing as they do much of the structure of the mouth and fangs, and the curious method of handling these venomous creatures. The same exhibitor's dragon fly preserves exceedingly well the delicate tracery of the wings. Close by Mr. J. P. Miller has two prints of the young cuckoo in the act of ejecting respectively an egg and a nest mate from the nest. The former is the more convincing photograph.

Mr. F. Martin Duncan, well known for his remarkable photographs of submarine creatures, shows a picture of the Eledon, a species of Octopus, engaged in a duel *a la mort* with a crab. His chameleon pictures are also very good. Miss Marie Léon's study of edible snails from the Surrey hills also makes a good, as well as an instructive, picture.

Very interesting is the series of six photographs by Mr. O. G. Pike, showing the progressive stages of a chicken emerging from its shell. The prints show in succession the newly-laid egg; the egg twenty-one days after, as taken from the incubator, the shell having been pierced by the chick to admit air; the appearance of the shell after further attacks on the shell by the bird from the inside; and the further stages up to the escape from the shell. The last print showing the chick surveying the wreck of its prison is very good.

There are a few examples of colour photography, but they are not inspiring. Mr. J. G. Jackson has utilised the carbon process, with three layers of differently coloured tissues superimposed, in the production of his exhibit, but it leaves much to be desired. Mr. S. R. Brewerton's fruit study is more successful, and is by the imbibition method of Sanger Shepherd. Miss Acland has two photographs in colour, the base being a pink carbon, the yellow and blue being added by imbibition. Mr. Otto Pfenninger has employed Dr. Jumeaux' process in getting his results, which do not, however, encourage one to think that colour photography in its perfect state is very near the popular grasp.

Mr. W. M. Martin shows photography adapted to the study of comparative anatomy. There is in the South Kensington Museum (Natural History) a case showing the progressive stages in the hatching of the chicken from the egg and in the frame now under notice. Mr. Martin has a series of photographs, seventy in number, showing the embryology of a chicken. Each photograph is fully described upon the mount and shows the expenditure of a considerable amount of skill, time, and patience. One of the photographs is taken by means of X-rays and the remainder some by transmitted light, others by a combination of transmitted and reflected light.

Among the miscellaneous exhibits the portrait taken by means of ultra-violet rays by Mr. Edgar Senior will arrest attention. In making this photograph the screen devised by Professor R. W. Wood to cut off all visible radiation was employed. Close by hang four examples of a method of photographing in low relief, claimed by Dr. F.

Detlefsen as his own. We have no particulars of the method, but the results do not make one feel the deprivation very seriously.

Mr. R. H. Baskett exhibits two frames of lace and wallpaper designs, produced by photographic means, from a small piece of lace, the leaves of common ragwort, bramble, forget-me-not, etc. The element, whatever it may be, from which the design is to be made, is reflected in two silver-surfaced mirrors and photographed in a manner described by the exhibitor, who points out that an endless number of designs can be produced of the greatest value to designers and art workers. Certainly, the few specimens shown have great promise, some being exceedingly beautiful and decorative.

The Rev. J. M. Bacon's balloon pictures are very similar to those he has shown on previous occasions, and do not call for much comment. With his daughter, who lectured on Monday last at the Gallery upon the camera and the balloon, he keeps this field of work very much in his own hands, and one cannot help feeling that, so thorough has he been, that there is little more that the balloon photographer can show us.

Before closing this notice it is only just to mention Dr. Rodman's radiographs of the Mollusca, which demonstrate in a very convincing manner the internal anatomy of shell. The exhibit speaks well of the author's skill, the delicate details of the substance of the shells, and their construction being excellently rendered.

Finally, it may be pointed out that this section must be taken no less seriously than the pictorial. A hurried examination will reveal little, while a careful inquiry into every exhibit will show us much that we may well emulate, even though we find much that calls for the reverse of praise.

THE DEFENCE OF BRITISH WEIGHTS AND MEASURES.

FROM the British Weights and Measures Association, of 25, Victoria Street, London, S.W., we have received a pamphlet written with considerable vigour of argument in favour of the retention of the existing system of British weights and measures, as against the adoption of the metre. The opening sentences of the pamphlet are as follows:—

"The persistent efforts of the advocates of the French metric system to get it enforced in the British Empire have brought into being the British Weights and Measures Association, whose primary object is to combat the metre. It also seeks to standardise and simplify British imperial weights and measures so as to make them in the greatest degree available for all purposes.

"There is a risk that the metric advocates will be successful if opposition is not organised, for the tendency is to let judgment go by default on account of the ignorance which prevails as to what the suggested reform really means to Britons. Believing that the enforcement of the metre in the British Empire would be a national calamity, we seek not only to organise those whose studies of the subject have enabled them to see the hollowness of the metric pretensions, but also to provide means of educating those who now directly support the metre by reason of their knowledge being limited to theoretical application, and of those by whose apathy the movement receives negative support and who may possibly have never had occasion to give the subject a thought, but who will be sufferers by it should it be enforced."

Our readers who have to deal with paper, cardboard, and the like, will, perhaps, be the more interested in the following, among many other concrete objections, to the "metric" system which are quoted in the pamphlet:—

"Throughout the Anglo-Saxon race paper is bought and sold by the lb.-weight and inch measurement. A man in the trade can judge to a nicety the weight of a paper by its feel. If you take the inch and pound away from him you take his trade off him, and compel him to begin learning afresh. So in cardboards and similar goods, the custom is becoming more general to buy and sell boards by the 'points,' or mills, thick, and the difference of one point (a thousandth of an inch) is often the difference between a fair profit or a considerable loss. Here again their micrometers and other measuring machines and gauges would needs be thrown away. Every repeat order that came in would require the lbs. of ink previously used transposing to grammes, and inches of paper to millimetres. The common size of 20 by 30 would then be simplified to 508 by 762

and the common crown 8vo, 5 by 7½, would appear as 126.997 by 190.496."

Again, in reference to the general aspect of the controversy, we read:—

"Measures of weight and of volume relate practically to the present and to the future, but measures of length, particularly in a great manufacturing nation, are linked irrevocably to the past. No Act of Parliament can obliterate them. It is considerably over 100 years since the metre was introduced into France, but neither fines, imprisonment, republican nor autocratic terrorism have killed the old measures of length. The manufacturers use them to-day, and the people also where they dare. Many engineers in metric countries concede the fact that the metre was an unfortunate length to adopt. The metre itself is too long even for large engineering work, the decimetre too short, and the millimetre is too long for fine work. The foot, the inch and the mill are ideal dimensions, and from one end of the world to the other are identical in length amongst the English-speaking race. To introduce the metre and its derivatives would be to introduce confusion where there is now uniformity. This anarchy would remain beyond the third and fourth generation, it would remain so long as the metre was enforced. The metre has neither virtue nor convenience in it; it is an unnatural length and must of necessity create trouble wherever and whenever enforced, so long as human beings are what they are to-day."

We note that the association is seeking to enlarge its membership. From time to time we have placed the aims and objects of the Decimal Association before our readers; we now have pleasure in giving equal publicity to the other side of the controversy.

Exhibition.

EDINBURGH AND MIDLOTHIAN.

The Edinburgh and Mid-Lothian Industrial Competitive Exhibition was opened in the Waverley Market, Edinburgh, on Friday last by Mrs. Burnet Smith (Annie S. Swan) and presided over by Lady Cranston. The Lord Provost and Lady Cranston have given their generous support to what may now well be regarded as an institution in the city. For the eighth year in succession the Exhibition has been held with ever-increasing popularity and success, until now the entries number 4,385.

The awards in the photographic sections are as follows:—Open Section.—Landscape: 1, R. M. Readdie, Edinburgh; 2, J. E. Latharn, Manchester; 3, Alexander Allan, Edinburgh. Animals: 1, R. M. Readdie, Edinburgh; 2, J. Dunlop, Motherwell; 3, W. H. Lindsay, Hamilton. Flowers, Fruit, and Still Life: 1, James Dunlop, Motherwell; 2, S. G. Kimber, Southampton; 3, Alexander Allan, Edinburgh. Portraiture: 1, John Smith, Hastings; 2, W. H. Lindsay, Hamilton; 3, S. C. Burgess, Ashby-de-la-Zouche. Child Portraiture: 1, W. H. Lindsay, Hamilton; 2, Mrs. Turnbull, Hawick; 3, J. A. T. Sturrock, Edinburgh. Architecture: 1, S. G. Kimber, Southampton; 2, James Dunlop, Motherwell; 3, R. M. Readdie, Edinburgh. Figures and Genre: 1, S. G. Kimber, Southampton; 2, Alexander Allan, Edinburgh; 3, James Dunlop, Motherwell. Snapshots.—1, Arthur W. Walburn, West Hartlepool; 2, W. H. Lindsay, Hamilton; 3, R. Dunlop, Motherwell. Seascape and Marine: 1, David H. Munro, Edinburgh; 2, D. Littlejohn, Glasgow; 3, Arthur W. Walburn, West Hartlepool. Any Subject (N.C.): 1, R. Lunn, Juniper Green; 2, J. A. T. Sturrock, Edinburgh; 3, S. G. Kimber, Southampton. Enlargements: 1, R. Lunn, Juniper Green; 2, Alexander Allan, Edinburgh; 3, J. A. T. Sturrock, Edinburgh. Carbon, and Sepia Platinotype Work. Landscape: 1, J. E. Latharn, Manchester; 2, Alexander Allan, Edinburgh; 3, S. G. Kimber, Southampton. Local Section.—General Photography: 1, William Bryce, Glasgow; 2, G. Sutherland, Edinburgh; 3, Adam Russell, Wishaw. Animals: 1, Albert Haynes, Alderley Edge; 2, J. S. Bryce, Lanark; 3, Isaac Lightbody, Hamilton. Flowers, Fruit, and Still Life: 1, A. Ramsay, Wishaw; 2, Thos. A. Thomson, Edinburgh; 3, G. Graham, Girvan. Portraiture: 1, R. N. De Pinto, Leith; 2, James Fallow, Wishaw; 3, J. A. T. Sturrock, Edinburgh. Child Portraiture: 1,

Albert Haynes, Alderley Edge; 2, James Fallow, Wishaw; 3, J. Jack, West Calder. Architecture: 1, Albert Haynes, Alderley Edge; 2 and 3, John Anderson, Belfast. Figures and Genre: 1, John Anderson, Belfast; 2, Wilton Rex, 12, Linkfield, Musselburgh; 3, David Munro, Edinburgh. Street Scene or Scenes: 1, Albert Haynes, Alderley Edge; 2, Robert Dykes, Edinburgh; 3, J. A. T. Sturrock, Edinburgh. Snap-Shots: 1, George Dunn, Edinburgh; 2, G. Graham, Girvan. Seascape and Marine: 1, David H. Munro, Edinburgh; 2, R. Lunn, Juniper Green; 3, Albert Haynes, Alderley Edge. prize list will be continued in our next issue.

FORTHCOMING EXHIBITIONS.

October 15-29.—Coatbridge Photographic Association. Hon. Sec. Geo. W. Campbell, Ailsa Cottage, Coatbridge, N.B.
October 19-22.—Rotherham Photographic Society. Hon. Sec., C. Hemmingway, Tooker Road, Rotherham.
October 26-28.—Watford Camera Club. Hon. Sec., H. G. T. foot, 3, The Parade, Watford.
November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretaries, L. C. B. Appleby, Barnbygate House, Newark.
November 2-23.—Plymouth. Hon. Sec. Photographic Society, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.
November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.
November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec. James Dunlop, Myrtlebank, Motherwell.
November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.
November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-O'Connell, 52, Frederick Street, Sunderland.
November 17-18.—Braintree and Bocking Camera Club. Hon. Sec. W. H. Tilston, 81, High Street, Braintree, Essex.
November 17-19.—Darwen Photographic Association. Hon. Sec. J. G. Thomas.
November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
November 22-23.—Ipswich Camera Club. Hon. Secretary, R. Sutton, 37, Henley Road, Ipswich.
November 23-26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.
November 24-25.—Isle of Thanet Photographic Society. Hon. Sec. G. W. Simmers, Aberdeen House, Ramsgate.
November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.
November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarnock Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.
December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.
December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-10 West 101st Street, New York.
December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.
December 13-20.—Southampton Camera Club. Hon. Secretary, G. Kimber, Oakdene, Highfield, Southampton.
December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.
January 12-14, 1905.—Boston Camera Club. Hon. Sec., H. M. Hames, 65, West Street, Boston.
January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.
January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905. — Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Isot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

THE MAKING OF A WELSBACH MANTLE BRIEFLY TOLD.

The incandescent gas mantle was invented by Auer von Welsbach in 1885, and patented all over the world. The manufacture and use of mantles was first taken up in Austria, and has since found its way in all of the civilised countries where gas is introduced. At the present time, writes "The Scientific American," it is estimated that no less than one hundred and fifty millions of mantles are manufactured annually. In the United States, although there are about forty millions manufactured annually, the industry is only partly developed. The public is gradually learning to use the mantle. The mantle is made as follows:—A "cone" or spool of No. 40 white cotton thread is knitted into a "stocking" or hose, about two inches in diameter. This stocking is thoroughly washed and dried. Then it is saturated with a solution of nitrate of thorium and one per cent. of nitrate of cerium. The thorium is manufactured from a sand called monazite, which is found in Brazil and in the State of Carolina, and is rather expensive, being sold at 6.50 dollars per pound. One pound of nitrate of thorium yields from 300 to 340 mantles, depending on the quantity distilled. After the cone has been washed and dried it is either cut to proper size and impregnated with the thorium solution, or is first impregnated and then cut to the required lengths. The impregnated stockings after being cut and dried are sewed at one end with asbestos thread, so as to form a head provided with a loop, which serves to hold the mantle in process of manufacturing and when in use on the burner. Then the impregnated stocking is hung on a wire by an asbestos loop, and heated in a gas flame of the Bunsen type. This is done in order to burn out the thread. The next process is called the shaping. The mantle now consists only of ashes of thorium (oxide of thorium) and is carefully held over a Bunsen flame, and gradually given the right shape, at the same time being hardened. As soon as the mantle is shaped and hardened it is practically completed; but in order to protect it from breakage it is "dipped" in a stiffening solution. There are many forms of "dip," but the one most used is made of soluble cotton (gun-cotton) dissolved in good alcohol and acetone. To this mixture castor oil and shellac are added. Before the mantle can be used on a burner this "dip" or coating must be burned off. The method employed in the manufacture will be described in detail in an early issue, and fully illustrated.

IPSWICH Social Settlement Camera Club.—The first meeting of the winter session was held on Friday night. The subject for the evening was "Flashlight Photography." Mr. Grix showed various methods of taking photos by flashlight.

New Books.

"Science and Practice of Photography." By Chapman Jones, F.I.C., F.C.S., F.R.P.S. Fourth edition. Rewritten and greatly enlarged. 569 pp. London: Iliffe and Sons, Ltd. 5s. net.

For some years "The Science and Practice of Photography" has been the textbook of many photographic technical schools and classes, and in the sixty-eight chapters every section of the subject receives careful treatment at the hands of the author, whose style is extremely simple and lucid. In this new edition the whole work has been most carefully gone through and brought up to date, a process rendered necessary and desirable by the large amount of photographic progress that has been achieved since the publication of the last edition. The work does not pretend to teach either chemistry or optics, but only to make clear to the student the matters that immediately concern him, and to enable him to use intelligently the methods given in his practical work.

One of the added chapters treats of the developable image. The theory that light, when it produces a developable image in an ordinary gelatino-bromide plate, causes decomposition of the silver bromide, in the opinion of the author, has long been untenable. A mechanical working hypothesis has been suggested.

Interesting chapters on the more exact testing of sensitive plates by the use of the Chapman Jones Plate Tester, and on measuring and comparing opacities are included, but, as the author remarks in his preface, "only the fringe of this subject is touched." If it were possible to write a useful treatise on this matter, the aim and scope of the present volume would render its inclusion impossible.

"The Optics of Photography and Photographic Lenses." By J. Traill Taylor. 98 illustrations. 270 pp. Third edition. With an additional chapter on Anastigmatic Lenses by P. F. Everitt. Price 3s. 6d. London: Published by Whittaker and Co., 2, White Hart Street, Paternoster Square, London, E.C.

Much of the matter in this little book was originally published in the columns of the JOURNAL more than twenty years ago, and some of it is even older. When Taylor wrote the various articles and delivered the many little discourses upon which the work is based, optical science was a very different thing from what it is to-day. It is not unjust to his memory to say that his life's work was practically over when the anastigmatic era set in. Hence it is that the first edition of the book, which was published about twelve years ago, contained little or no reference to the revolutionary labours of Abbe, Schott, Rudolph, Von Hoegh, and many other Continental optical savants. In a measure this deficiency is made up in the present edition by Mr. P. F. Everitt, who devotes the thirtieth chapter to a concise view of the principal anastigmats introduced since the year 1898, when the Concentric was patented by Dr. Schroeder and Mr. J. Stuart. Mr. Everitt, however, is of opinion that the Antiplanet introduced by Dr. Adolph Steinheil about 1879 "may be regarded as the forerunner of the Anastigmats." Steinheil's intention, adds Mr. Everitt, evidently was to construct a lens conforming, as closely as circumstances permitted, to the necessary conditions for correcting spherical aberration and astigmatism as subsequently published (that is, in 1897) by Dr. Rudolph Steinheil. These conditions are briefly quoted. Following the "Concentric," the Abbe-Rudolph triplet of 1889 is mentioned as being the first of the Zeiss lenses to be introduced, although in its construction apochromatism rather than anastigmatism appeared to be aimed at. To the Protars, patented by Dr. Rudolph in 1890, is assigned the distinction of being "the first successful attempt to supply photographers with an achromatic objective combining spherical correction with anastigmatic flatness of field." Thence, step by step, we are taken through the subsequent work of Dr. Rudolph, Dr. R. Steinheil, Dr. Kämpfer, Von Hoegh, Dr. Harting, and other German patentees. The achievements of H. D. Taylor and H. L. Aldis in this country also receive recognition. Each lens is diagrammatically illustrated, and the introductory parts of the chapter which deals with the nature of the glasses and the manner in which they are to be used in correcting errors should enable the "users of photographic lenses," for whom Taylor's book was avowedly planned, to understand in some degree the optical problems involved in modern lens construction. The other thirty-eight chap-

ters of the book have, where necessary, been subjected to revision, but the volume would not have suffered if the pruning knife had been occasionally applied to it, such paragraphs as: "Maps or charts A lens of the rapid class is most advantageous for this kind of work," having a distinctly obvious if not belated appearance. But on the whole, Taylor's book in its present form does not recede from the position it assumed on its first publication. It is a popular and easily comprehended introduction to the non-mathematical optics of the photographic lens used on the camera and the projection lantern, and it includes a great deal of general information which the photographer should find useful in his work. A word of reference is due to the historical portions of the volume, which should interest the student of lens evolution.

Patent News.

The following applications for patents were made between October 3 and October 8, 1904:—

Polychrome Photographs.—No. 21,210.—"Improvements in and relating to polychrome photographs." (Charles Louis Adrien Brasseur.)

Cameras.—No. 21,285.—"Improvements in Cameras." (John Stratton Wright.)

Cameras.—No. 21,295.—"Improvements in photographic cameras." Date applied for under Patents Act, 1901; October 14, 1903, being date of application in United States. (Magnus Niell.)

Developing Apparatus.—No. 21,335.—"Improvements in photographic developing apparatus." (James Wyndham Meek.)

Cameras.—No. 21,439.—"Improvements in photographic cameras." (Alexander Milne.)

Camera.—No. 21,527.—"Panoramic Camera." (William James Johnston.)

GILMOUR AND DEAN, LTD.—Registered October 3 in Edinburgh. Capital £30,000, in £1 shares. Objects: To acquire as a going concern the business carried on under the style of Gilmour and Dean at 50, North Hanover Street, Glasgow, with all or any of the assets appertaining thereto, and to carry on the same and the businesses of engravers, lithographers, printers, photographic and colour printers, die sinkers, stationers, etc. Registered office, 50, North Hanover Street, Glasgow.

"We do not, as at present advised," says the "Standard," "entirely condemn the Carlsbad authorities who insist on suppressing the amateur photographer." Neither do we when he makes himself a nuisance and persists in following persons of note with his camera, as he did in the case of Pierpont Morgan, to the exceeding annoyance of the would-be victim. I have recently come across a caricature of President Roosevelt under a broad grin, which probably the President would give many dollars to withdraw from circulation. There was money in it for the photographer, and probably this is a clue to the objectionable practice. It is presumed that public personages are public property, but good taste might be exhibited even in laying down such a questionable dictum. Our own King, in spite of his well-known good nature, must feel the ordeal terribly trying at times, and I have seen at least one snap-shot of him vainly endeavouring to cover his face with his hands. Some sort of a "black list" is necessary that the many innocent shall not suffer with the few guilty, and, although one would scarcely object to photographs of public men on public occasions, the privacy of domestic life might be left intact. It is not difficult to foresee that steps will have to be taken some time in the near future to protect the victims of the irresponsible or the mischievous snapshotter, and the Paul Pry of the camera will have an unhappy time. Thoughtlessness and the want of appreciation of the rights of others may have something to do with the nuisance. The man who makes exposures on fortifications, and is promptly hauled before the authorities, generally does it because he doesn't think, and not because he has found the picturesque or expects to make money out of it. A little discretion and good feeling on the part of the photographer is all that is needed to obviate any necessity for a Carlsbad suppression in this country.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
24	Southampton Camera Club	In Birdland with a Camera. Illustrated. Mr. O. G. Pike.
24	South London Photo. Society	Enlarging Processes. Mr. H. Edmeads.
25	Glasgow Southern Photo. Assn	The Hand Camera, and What Can Done With It. Mr. Wm. A. Frame.
25	Rodley and District Ph. Soc.	A Bit of Old England. Mr. Mackay.
25	Hackney Photo. Society	Members' Lantern Slides.
25	Nelson Photographic Society	Members' Question Evening.
26	North Middlesex Photo. Society	Scottish Snapshots. Mr. F. Mortimer.
26	Boro' Poly. Photo. Society	Hints on Lantern Slides. Mr. Algernon Brooker.
26	G.E.R. Mechanics' Institution	Lantern Slide Making. Mr. H. Bennett, F.R.P.S.
26	Cricklewood Photo. Society	Lantern Slide Making. Demonstrated by Mr. T. C. Spencer.
26	Edinburgh Photo. Society	The Camera: and the Optics of Photography. Mr. Robert F. Sherar.
27	Royal Photographic Society	A Popular Talk on Colour Photography. Mr. T. K. Grant.
27	Camera Club	The Results of Recent Exploration in Egypt. Professor Flinders Petrie, D.C.L., F.R.S., &c.
27	Rugby Photographic Society	Photographic Novelties. Members.
27	Watford Camera Club	Second Annual Exhibition at the Club. Exchange.
27	London and Prov. Photo. Asso.	Open Night.
27	Southport Scientific Societies	The Innocents Abroad. Mr. F. C. Clifton.
27	Liverpool Amateur Ph. Assn.	Nosces from some Old English Stone. Mr. Adolph W. Beer.
27	Hull Photographic Society	North Wales. Mr. Godfrey Bingley.
28	Wakefield Photo. Society	Photographic Picture Making. Mr. Thos. Heaps.
28	Boro' Poly. Photo. Society	Instruction Evening. Development.
28	Watford Photographic Society	Printing Methods—Gum Bichromate.
28	Royal Photographic Society	The Engadine and Lucerne. Mr. Samuel J. Beckett, F.R.P.S.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 13. Mr. Thomas Bedding, F.R.P.S., in the chair.

The principal business of the meeting was the bestowal of the annual Henderson award for the best paper read during the past year. The voting ultimately went in favour of Mr. J. S. Teape for his paper on "Intensification Without Metallic Salts," which was reprinted in the BRITISH JOURNAL OF PHOTOGRAPHY for April 1904.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held on Friday the 14th inst. Present: Messrs. Alfred Ellis, F. A. Bridge, A. Mackie, Lang Sims, S. H. Fry, H. C. Spink (Brighton), H. S. Mendelssohn, E. Scammell Wm. Grove, H. Edmond S. Hull, P. Lankester (Tunbridge Wells), H. A. Chapman, J.P. (Swansea), W. Gill (Colchester), and P. E. Marshall (Hon. Solicitor).

Mr. Alfred Ellis (President) in the chair.

The minutes of the previous Committee meeting, held on September 9 were read and confirmed. The draft report of the Committee for presentation to the members at the annual general meeting on the 21st inst. was read and approved.

The draft prospectus of the Committee's scheme for granting certificates of competence to operators, assistants, etc., was read. That it should be brought forward and discussed at the annual general meeting had already been arranged, and in order that a full opportunity should be given for due consideration of the provisions before the Committee should finally decide upon issuing it in its complete form, it was decided that the draft should be handed to the Editor of the BRITISH JOURNAL OF PHOTOGRAPHY for publication.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION, HULL BRANCH.

A MEETING of the Hull Branch of the Professional Photographers' Association was held on October 12, Messrs. Wellstead, Fussev, Duncan, and the Hon. Secretary being present. "Examinations for Assistants" and the proposed "Benevolent Fund" were on the agenda.

Mr. Fussey said employers would welcome a scheme which would enable them to discriminate between capable assistants and the large number of unskilled people who answered advertisements. There were many grades of photographers, but the class of inexperienced assistants seemed to be growing, and threatened to crowd out the better men altogether. He hoped the Association could arrange for practical tests, and not set too high a value on purely theoretical knowledge. Mr. Duncan said the ability to make money was the best sort of test, whether in master or assistant. Mr. Wellsted hoped it would be possible to secure a studio in town in which operators and retouchers could within a specified number of hours produce test work certified by the Association. It would have a peculiar value, and would appeal to those photographers who believed that a good man found himself at home anywhere, while such a test would be a trap to the duffer. The Hon. Sec., in pressing the claims of the proposed new Benevolent Fund, said that in February, 1902, when Mr. Lang Sims brought this matter forward, the then president of the P.P.A., Mr. Thomas Bedding, had earnestly urged the opening of a fund to alleviate the distress prevalent at that time. He had remarked that "the rapid distribution of the late Benevolent Association funds had destroyed the one and only centre towards which an unfortunate man or woman might direct his or her gaze." What was true then was much more so now, and he hoped the Hull Branch would do its share in this altruistic effort. As apologies for non-attendance from several members had been sent, it was decided to call another meeting in Hull soon after these important matters had been discussed in London.

HULL PHOTOGRAPHIC SOCIETY.

This society opened the winter syllabus on Thursday, October 6th, by a smoking concert of excellent proportions. Their room was full, and promises well for success and enthusiasm. The president spoke at some length upon the possibilities of photography as an art, from a pictorial point of view, and made much impression when he pressed each one to specialise. He also gave advice upon subjects which each one present might undertake, and proved conclusively that the best work and negatives was usually produced during the fall of the autumn, through the winter, and nearly spring, therefore there was no need to put away the camera, but have it ever ready for spare moments and unusual effects, and he was sure they would profit in their pictorial aspirations. It was also a fine opportunity to look through the existing negatives and pick out and study their merits with a view to making lantern slides, enlargements, and probably pictures for some public exhibition and for the glory of their friends. He also pointed out the extreme advantage of pulling together and for each member to attend regularly during the weekly demonstrations and lectures (this year's being the strongest and best that it is possible to have arranged), and feeling as if they had an individual interest in his fellow members, and by so doing it would not only be to their mutual advantage, but the furtherance of a noble, instructive, and most fascinating art as well as hobby. He gave many branches which might be taken in hand, according to the taste or ability of a member, and we believe a new light has been struck in the Hull society which should prove second to none outside London, and it only needs application to be on a par with several societies in the country, which have made their mark by combined vigorous enthusiasm, and we sincerely hope Hull may secure a share of what they appear to be aiming at. The harmony was contributed by some half-dozen gentlemen, friends, and members. The Rev. C. O. Stewart presided most ably at the piano, and also contributed several popular songs.

WILSTER AMATEUR PHOTOGRAPHIC SOCIETY.

The opening meeting of the session in connection with this society, which was established in 1885, was held in the club-rooms, the Museum, College Square North, on Monday last. Mr. David Elliott, B.A., T.C.D., presided, and, in expressing the pleasure it gave him to meet the members and friends of the society at the opening of the winter session regretted that since their last meeting they had lost one of the oldest members and workers, the late Mr. Alexander Tate, C.E., for many years a member of the council of the Photographic Convention of the United Kingdom. As regarded amateur photography, from the number of cameras to be seen in daily use and the increasing lists of dealers there evidently was an amount of pleasure to be gained in the hobby, and he hoped that the Lord Mayor's gold

medal would be well competed for. Mr. Thomas N. Murray, hon. secretary, read a lecture, written by Mr. C. H. Hewitt, on "Portraiture," illustrated by some very fine slides taken by himself. One of the slides showed a portrait of Miss Dorothy Catherine Draper, taken by her brother, Professor John William Draper, M.D., LL.D., of New York University, early in the year 1840, which is almost certainly the earliest sun picture of the human face.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

THE session of this society opened on Tuesday evening last with a lantern lecture at the Victoria Hall. Mr. L. Hough, the president, presided, and offered a few words of welcome to Mr. F. Martin-Duncan, whose lecture on "Denizens of the Deep, or Studies in Marine Photography" was greatly enjoyed by a large attendance. Marine photography, the lecturer said, had received comparatively little attention, but it was full of charms and interest, and when once taken up was never dropped again, but became a life-long hobby. The apparatus required was not of so elaborate a character as might be imagined, but a large and inexhaustible stock of patience was necessary, and sometimes he had to wait a fortnight and three weeks before he was able to obtain a successful photograph. The lecture was illustrated with a number of views thrown on the screen, and constituted not only an example of what may be achieved in the instruction of this kind of marine photography, but also a useful and instructive natural history lesson. Photos of the more familiar objects of the sea-shore were shown, some of the more interesting being pictures of various kinds of seaweed, marine insects and animals, small fishes, star fish, the sea urchin, crabs, sea worms, cuttle fish, and the octopus. The lecturer told of an exciting adventure he had in the Bay of Naples with a large octopus, whose tentacles seized round the legs and dragged him into the water. He was rescued with difficulty by a Neapolitan boatman. At the close of the lecture the president stated that the society numbered 120 members, and was most flourishing. Persons interested in photography were invited to attend the fortnightly meetings at the Oriental Cafe in the Market Place, where a dark room was set apart for the use of members.

ARCHITECTURAL ASSOCIATION CAMERA CLUB.

At the first meeting of this club, held on Tuesday evening at the Royal Architectural Museum, 18, Tufton Street, Westminster, a paper on "Westminster Abbey," illustrated by over a hundred lantern slides, lent by Mr. S. B. Bolas, was read by Mr. D. M. Mackenzie. Mr. Francis R. Taylor, chairman of the club, presided. Mr. Mackenzie briefly told the story of the Abbey's origin, rise, and progress, and, having shown and explained a ground plan of the Abbey church and monastic buildings, took his audience down the nave into the choir to see Blore's stalls and J. L. Pearson's organ case, through the north and south transepts, round the ambulatory chapels from south to north, pointing out some of the more noteworthy monuments, and having made a survey of Henry the Seventh's chapel and its north and south aisles, and an examination of the galaxy of royal tombs in the Chapel of the Confessor, concluded an interesting hour-and-a-half's lecture with glances at the chapter-house and its crypt and the cloisters, leaving the historic buildings by way of the Abbot's Courtyard. In proposing a vote of thanks to Mr. Mackenzie, with whose name that of Mr. Bolas was coupled, Mr. Francis Hooper remarked that now that the Architectural Association had removed its headquarters to the very doors of the Abbey, they might expect that their students would give its architectural treasures closer attention. He much regretted that, under the present régime, so few facilities were placed in the way of bonâ-fide students for sketching, and especially that permits were granted for such short periods. Mr. John D. Crace, in seconding the vote of thanks, remarked that the Council of the Royal Institute of British Architects ought to be moved to unite with the committee of the association in requesting that every facility for sketching and measuring at leisure should be granted to properly accredited architectural students.

DERBY PHOTOGRAPHIC SOCIETY.

THE annual meeting of this society was held at Derby, under the presidency of Mr. C. B. Keene. The annual report alluded to the recent visit of the Photographic Convention to Derby. There were

ninety-five members, and the accounts showed that the finances were in a satisfactory state. Sir William Abney and the Hon. F. Strutt were elected patrons of the society. Dr. E. Collier Green was elected president in succession to Mr. G. Herbert Strutt, and Mr. G. T. Lee and Mr. W. R. Bland accepted office as vice-presidents, Mr. Keece having expressed a desire to retire from office, though promising to remain an active member of the society. Mr. J. B. Copeland, who now lives away from Derby, resigned the hon. secretaryship, and Mr. A. H. Bennett was appointed as his successor. Mr. F. H. Gandy was appointed hon. treasurer.

News and Notes.

"HINTS on Lantern Slides, with Examples," is the title of lecture to be given by Mr. Algernon Brooker at the Boro' Polytechnic Photographic Society on Wednesday evening, October 26.

At the exhibition of the Brentford Photographic Society, to be held in March, 1905, the judges will be Messrs. Thomas Bedding, F.R.P.S., R. W. Craigie, and J. C. S. Mummery.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for current month has been awarded to E. O. Henrici, Esq., 62, The Common, Woolwich, for his negative "The Matter-horn."

MESSRS. EYRE AND SPOTTISWOODE announce, in connection with their Woodbury lantern lectures by prominent authors, that they have arranged for two further lectures, which, together with full sets of slides, will be sent free of charge to any responsible applicant.

THE members of the Darlington Camera Club opened their winter session on Thursday last, when Mr. R. W. Chapman gave a demonstration on "Flashlight Photography," and in the course of his experiments photographed the company present.

ROYAL Photographic Society.—At the New Gallery, 121, Regent Street, on Monday, October 24, Mr. John H. Avery will give an account of "A Journey to Fanatical Fez," illustrated by his own photographic lantern slides. Gallery opens at 7 p.m., lecture at 8 p.m.

WHITBY Camera Club.—At the annual meeting the report showed a very satisfactory state of affairs, and promises of several new members with the opening of the winter season. Mr. G. S. French was elected president, and Mr. Woodhouse Parkinson, Ocean Road, Whitby, hon. secretary.

A WELL got-up little booklet from the well-known firm of Wratten and Wainwright, dry plate makers, of Croydon, has been sent us. It contains full particulars of the "London" plates, the reputation of which, for reliability, has been long recognised, particularly in tropical climates. Many excellent half-tone reproductions illustrate the price list.

NORFOLK Photographic Society.—At the first meeting of the winter session, held at Strangers' Hall on Friday last, Mr. A. E. Coe gave a demonstration of the best method of reducing and intensifying those negatives capable of improvement by these processes. It was decided later in the evening to hold the annual exhibition in February next.

SOUTH London Photographic Society.—The elementary evenings of this Society started off in fine style with a lecture on "Photographic Apparatus" given by the hon. secretary, H. Creighton Beckett. The Committee are glad to know that many unattached photographers have availed themselves of the offer made some weeks ago, and have applied for cards of admission to these evenings. Fuller particulars can be obtained from Mr. Beckett, 44, Edith Road, Peckham, S.E.

MRS. ALSTON begs to announce that, owing to the increasing number of her pupils, she has been obliged to remove her studio from 175, New Bond Street, to larger and more commodious premises on the first floor at 52, New Bond Street. At this address free demonstrations of crystalloleum painting, a new and beautiful process for tinting photographs, rivaling the finest miniatures on ivory, are being given daily from 11 a.m. to 12 noon.

SOUTHAMPTON Camera Club. The members held a meeting on the 17th inst., when, in the absence of Mr. W. D. Welford, F.R.P.S.,

who was unable to keep his appointment, Mr. G. Vivian very ably filled the gap, and entertained the company with his instructive lecture on "Old Southampton," which was illustrated by many incidental and interesting lantern slides. The lecture was much appreciated, and Mr. Vivian was accorded a hearty vote of thanks for his excellent impromptu entertainment.

"COXIN" Competition.—Messrs. W. Butcher and Sons have asked us to draw attention to the fact that the "Coxin" competition closes on the last day of this month. There will be sixty-eight prizes. 1st, all. The 1st prize is a Humber standard motor bicycle; 2nd, Riley combined billiard and dining table; 3rd, "Monarch" gramophone; 4th and 5th, photographic apparatus. Duplicates of these first prizes will be awarded to the dealers who sold the bottles having the winning coupon.

THE Scenic Artists' Association proposes to hold next month the First Annual Exhibition of the works of Scene Painters, started at present. Scenic artists, theatrical managers, and others willing to lend models of theatres, sketches of scenes, properties, and costumes of historic interest, old playbills, posters, portraits of celebrated scene painters, paintings, drawings, and photographs of stage scenes, etc., etc., are invited to communicate with Mr. H. Lawrence Harrison, the secretary of the association, at 5, Robert Street, Adelphi.

SOUTH London Photographic Society.—This Society had quite a gala night recently, when, before a crowded audience, nearly 200 slides were passed through the lantern. A large number of the slides were prize winners in some recent competitions promoted by the photographic Press, and some very fine work was shown. A very pleasing feature of recent meetings of this Society has been the numbers of nominations for membership announced, and it is confidently believed that the active membership will pass the 200 mark by the end of the year.

THE first ordinary meeting of the session, in connection with the Newcastle-on-Tyne and Northern Counties' Photographic Association was held on Tuesday last, at the Young Men's Christian Association, Newcastle. A lecture was delivered by Mr. A. E. Cowling on "Architectural Photography for Beginners." Mr. J. W. Lyson presided. The lecturer, who is chairman of the Federation of the Photographic Societies of Northumberland and Durham, illustrated his discourse by the introduction of a number of very fine slides. The second ordinary meeting will be held on Tuesday, the 26th inst.

YORKSHIRE Philosophical Society: Photographic Section.—The annual meeting of the Photographic Section of the Yorkshire Philosophical Society was held in the Museum on Wednesday last. The report for the past session was read by the hon. secretary, Mr. E. Dennis Taylor, who recapitulated the chief events of the session. Dr. Tempest Anderson, M.D., was unanimously re-elected to the office of president. Mr. J. N. Kitching, and Mr. N. Bellerby, were re-appointed vice-presidents, and Messrs. H. Dennis Taylor, Standcliffe Mount Villas, and Malcolm Spence, Marygate, joint hon. secretaries.

ONE of the most impudent thefts of a work of art that have occurred in modern times has taken place at the National Portrait Gallery. Last Wednesday week one of the most valued miniatures in the nation's collection was stolen from its place in the screen-room on broad daylight, during the hours when the gallery was open to the public, and while the attendants patrolled the rooms. The missing miniature is a portrait of Baron Thomas Dimsdale, the great inoculator for small-pox, and was painted by Andrew Plimer. It was presented by Lady Dimsdale, wife of Sir Joseph Dimsdale, ex-Lord Mayor of the City of London, to the nation in 1880.

HILLSBORO' and District Photographic Society.—The annual general meeting of this society was held at Miss Makin's schoolroom, Hillsboro', on Wednesday last, the 12th inst. The secretary and treasurer each gave a very satisfactory report on the year's working. A good collection of the members' competition prints was exhibited. The prize winners were: for the monthly competitions, Mr. Z. Carr; for the president's special competition, Mr. W. T. Furniss. The new officers elected for the ensuing year are: president, Rev. T. Campey; treasurer, Mr. T. Carr; hon. secretary, Mr. B. F. Glossop, Southey Villa, Walkley Bank Road, Sheffield.

THERE was a small but interesting side show at the soirée of the R.P.S. which could not possibly have been seen by anything like the present. Professor R. W. Wood was to have shown in person the

latest results by his diffraction grating method of photography in colours, which he described some years ago before the society (BRITISH JOURNAL OF PHOTOGRAPHY, June 9, 1899), but at the last moment he was called away and his exhibits were shown by Mr. T. E. Freshwater, who again demonstrated the beautiful results obtainable by this process at the meeting of the Affiliated Societies at the New Gallery on Friday last.

On Friday evening last, the 14th inst., Mr. Alfred Ellis, the retiring President of the Professional Photographers' Association, entertained the members of his committee with Messrs. P. E. Marshall, hon. solicitor, and Thomas Bedding, F.R.P.S., Past-president, at the Eccentric Club, Shaftesbury Avenue, W. An admirable dinner was served to a party of eighteen. The President read speeches entirely out of order, and the only instance of insubordination was on the part of Mr. Bedding, who, instigated to rebellion by a majority of those present, persisted in proposing Mr. Ellis' health and congratulating him on the important work which crowned his year of office. A delightful evening was spent by all.

MR. WILLIAM F. SLATER, F.R.P.S., has arranged during the winter season to lecture and demonstrate before photographic societies on Messrs. R. and J. Beck's novelties in hand cameras and lenses, illustrated with lantern slides. Synopsis: Some Errors and Corrections in Photographic Lenses; Distortion; Chromatic and Spherical Aberration; Astigmatism; the New "Unofocal" Anastigmat Lenses; "Zambex" Cameras for Daylight Changing of Ordinary Flat Films; "Dai Cornex" Cameras for Daylight Changing of Plates; Telephotography; The Negative Lens; Comparison of Long Focus and Telephoto Lenses; The "Multiflex" Telephoto Lens; Telephoto Cornex Hand Camera; Depth of Definition; Focus of Infinity; The Use of the "Cornex" Index; A Simple Method of Testing of Shutter Speeds.

SCOTTISH Survey Work.—The list of contributions acknowledged in this month's number of the Transactions of the Edinburgh Photographic Society is truly a goodly one, and Mr. James Burns, who manages the survey section, is to be congratulated upon the result. The portion of old Edinburgh between the Castle and Holyrood is being made the subject of a special effort to get as complete a record as possible of its aspect, both past and present. "It would be a good thing if one of our local societies made a step in this direction," remarks a Glasgow contemporary, "as there must be in the possession of photographers in our city quite a wealth of material which would yield a record of what has passed and is rapidly passing away in our midst. In the survey section of the Edinburgh Society prints are taken from negatives which, in some cases, are only lent for the purpose, but nothing seems to be left undone which will help to make the section a success. In this way from prints and negatives given, and from copies of old prints and every available source, a record is made of old and historic places, many of which are still in existence, whilst others have completely altered in appearance or passed away altogether."

POSE FOR OBESITY.—An amusing story has been told by a man who had to appear in the Paris courts to answer a charge of vagabondage, writes a correspondent to the "Morning Advertiser." He was a very tall man and terribly thin. "What is your profession?" asked the president of the court. "I pose as a model for obesity," replied the prisoner. The judges were surprised to hear that this lean specimen of humanity should pose as an advertisement in order to encourage those who desired to reduce their corpulency, and sought a detailed explanation. "Why, it was in this way," replied the prisoner. "I was in the service of a manufacturer of chemical products which reduced obesity. I donned a mail of rubber which could be inflated like a pneumatic tube. Then I was photographed. Afterwards my portrait was exhibited in a case with the inscription, 'Before treatment.' The rubber was then deflated a little, and another photograph was taken entitled, 'After a month's treatment.' Finally I was divested of my rubber garment, and a photograph of my original self taken. It was labelled, 'After two months' treatment.' The poor vagabond then explained that the dead season of his profession began. No more photographs were wanted. Those that had been taken were used for an indefinite period. He had therefore to starve. Hence the charge of vagabondage preferred against him.

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE P.P.A. MEETING.

To the Editors.

Gentlemen,—At the annual general meeting of the Professional Photographers' Association, which will be held at the rooms of the Royal Photographic Society, 66, Russell Square, London, W.C., on (this) Friday evening, October 21, the committee will present their tentative scheme for granting certificates to photographic operators and assistants. Mr. Snowden Ward's suggestion for the formation of a benevolent fund will also be discussed.

As both these subjects are of importance to many outside the membership of the association, the committee will be pleased to have the attendance of any who may be interested.—I am, yours, etc.,

WILLIAM GROVE,

Hon. Sec. and Treasurer.

October 12, 1904.

[The above communication should have appeared in our last issue, but it miscarried in transit. Details of the proposed examination scheme are given in full in another part of the Journal. We trust that there will be a large attendance of photographers this evening at Russell Square, in order that both subjects before the meeting may be adequately discussed.—Eps. B.J.P.]

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—By your courtesy, in another part of the Journal will be found the draft prospectus of the first part of the association's scheme for granting certificates of competency to operators, assistants, etc., and I am desired to invite the attention of all who are directly or indirectly interested in the matter, and to ask their assistance in enabling the committee to inaugurate a system which shall be acceptable and useful equally to employers and employed. To this end the committee will welcome reasonable criticism, and, before deciding upon the conditions and provisions finally to be adopted, will carefully consider all suggestions placed before them. Our most useful critics will be those whose criticism is constructive, merely destructive criticism will help us very little, and the simplest and most easily understood method of conveying their ideas will be for those who desire to assist us to send a copy of the draft emended in such a way that it constitutes a complete prospectus of the scheme, embodying their own improvements. To facilitate this course I shall be pleased to send a printed copy of the draft upon request.

Owing to the wide differences there are in systems of conducting photographic businesses it has been found impossible to make provisions to meet every case exactly, and, where the necessity for compromise has arisen, an endeavour has been made to select that which appeared the most generally applicable. The importance of preserving the general applicability of the conditions I would impress upon the notice of those who may favour us with their comments.

In conclusion, may I remind your readers that the Professional Photographers' Association exists for the purpose of advancing the interests of professional photographers, and that its influence and power of carrying out its objects are dependent upon the support accorded it by the professional photographers of this country. The want which has long been severely felt, and which we are now attempting to provide for, is but one of the many pressing needs in professional photography that will be tackled in turn; but our progress would be quicker if the voice of the association were the voice of the majority of the profession. We are not impeded by want of able and willing workers to direct and carry out our schemes. We are not hindered for want of money, our trifling subscription provides for our current needs. What hampers us is want of loyalty on the part of those whose interest it is, and who should consider it their duty to accord us their active personal support.—I am, etc.,

WILLIAM GROVE, Hon. Secretary.

51, Baker Street, London, W.

THE PROPOSED BENEVOLENT FUND.

To the Editors.

Gentlemen,—I desire to state that if there is one member of the photographic profession in a position or qualified to press the claim of the proposed fund, I am that person. Naturally the reader will look down at the signature of this letter, and my signature represents my present position. On October 8, the same day that Mr. Watson's appeal appeared in your issue, my doctor sent me to bed, and I have been there more or less since that date, and have, therefore, had plenty of time for reflection. When one has gone for, say, forty years (taken all in all) almost in perfect health, save slight colds, etc., and is then brought sharp, without any warning, face to face with a blank wall (to use a figure of speech), and there is no turning or moving till that obstacle is removed, one's breath is almost taken away. I read Mr. Watson's letter in great pain and weariness, having undergone a somewhat painful (though minor) operation that same day, and have been obliged to lay up since that; though this has almost overwhelmed me, what would have become of my wife and children if this had happened ten or fifteen years ago, before my business was established, or I had assistants to take my place?

Now I am sure your readers will readily see this is the sort of case that if help was needed the benevolent fund might prove a lasting benefit to such a man and his family, that I appeal for subscriptions towards this grand and noble effort. I have pleasure in enclosing cheque for one guinea, and shall do all I can to further the same.—I am, yours, etc.,

October 17, 1904.

[We have handed our correspondent's cheque to the hon. treasurer of the P.P.A.—Eds. B.J.P.]

To the Editors.

Gentlemen,—I should be glad to pay a small annual subscription towards a Professional Photographers' Benevolent Fund. At the moment I could not find any other address to write to.—I am, faithfully yours,

W. MAYOR.

Leven, Fife, October 17, 1904.

[In last week's JOURNAL, p. 896, the address of the Hon. Sec. of the P.P.A. was given in full.—Eds. B.J.P.]

"ONE MAN AT THE SALON."

To the Editors.

Gentlemen,—The premier exhibitions have this year been, on the whole, very well treated by the lay Press, but I was surprised to find from one report in a London daily that the Salon was a one-man show. The learned critic here contributed five paragraphs, and, apart from the first, which is devoted to a verbose—not to say laudatory—criticism, in which such phrases as "most successful," "contributors and selection committee deserve heartiest congratulations," "commercial element reduced to the least possible dimensions," "members work together with rare skill and devotion," "animated by the single desire to infuse originality and artistic charm into a banal and not fascinating piece of mechanism," lead one to the expectation of a feast of good things. The last-quoted remark is rather suggestive of a wild goose chase, but it is evident that the writer's intentions are good.

The artistic notice continues somewhat in the strain following:

"Look, for instance, at Mr. William Bailey's 'Study in Scarlet,' a portrait well arranged and full of character, suggesting and revealing itself with perfect lucidity, yet delicately, and with a coy suggestiveness which is full of charm. Before such a picture one hardly feels the dualism of machine and artist, which, as a rule, makes itself too surely felt. The representative value of the picture is not sacrificed to the over-mastering impulse of the artist to make himself felt. It is a portrait of the sitter fixing and exhibiting the characteristics of the sitter, with something of the skill and intelligence of a fine draughtsman. Yet no one who has ever used a camera would suppose that the machine alone could do so much; it must first be mastered and controlled, and directed by an artist." Photographers will be flattered by the frequent use of the pleasant word "artist," and be no doubt envious of Mr. William Bailey's possession of a "machine" capable by its own volition of so much.

Compare Mr. Black's "Organ Player" with Mr. Bailey's "Study." Instead of the silvery opalescence which reveals forms and sinuities

in the most delicate modulations, Mr. Black pitches his picture in the deepest gloom. "Through the cavernous gloom a suggestion of something pallid—it may be a human face—and something that suggests a human figure can be discerned." The machine is being run by an imperious and over-mastering personality, who wishes to assert himself, to impress the spectator in some way. Such a master would drive his motor-car over newly-ploughed fields and through hedges and ditches, just to make himself felt and respected. "He'd wreck the machine just to show he was its master," and cut off his nose to spite his face. Really, there are some queer new machines on the market! "I find something of Mr. William Bailey's charm in the print of the girl 'Eating Bananas,' and in Miss Aurin's 'Mignonne.' The former is kept well within the centre keys, being neither too dark nor too white, and there are octaves above and below. The forms are pure and distinct, yet far removed from that superfluity of realisation which bores one so much in commercial photography." Other machines, other drivers.

The numerous works of Messrs. Noir and Blanc are generally well composed, and show great artistic skill and taste, with evidence of complete control of the machine, but how dark the gloom! The preponderance of black is depressing and monotonous. How vague and empty the blacks are. Look at the hair and environment of this figure, which look merely like clouds of fog or smoke. "It is therefore this rank unmanageableness of the blacks which makes one think that Mr. William Bailey and those who work as he does, by preference in the lighter keys, are wiser than the majority of exhibitors who revel greedily in gloom." Happy Mr. Bailey!—I am, yours etc.,

A. CHAFFEUR.

October 16, 1904.

NOTHING LIKE BUTTONS.

To the Editors.

Gentlemen,—Your editorial footnote to the letter by "Argus," published in the B.J.P. of October 14, leads us to the conclusion that you consider his remarks re sweating, etc., are specially directed at us. If that is so, and anonymous slanders are thus permitted, there is nothing to prevent any vindictive assistant who may have been discharged, or other evil-disposed person, from delivering a cowardly "stab in the back," while his identity remains concealed behind a "nom de plume." In case, therefore, your inference was correct, and that a personal attack was intended, we ask you in fairness to permit us to disprove any such insinuations, and show that, in connection with our firm, straightforward assistants have no cause of complaint. Our hours of business are from 9 to 6, one hour allowed for dinner; Saturday 9 to 4. No Sunday work, and no overtime excepting during the fortnight before Christmas. One week's holiday every year to each employee, salary paid. We employ now sixteen qualified assistants (exclusive of two apprentices, charwoman, and messenger boy). Two of these have been in our employ nearly sixteen years, four over six years, four over five years, two over four years, three over two years, and the other one, to complete the complement, seventeen months. In 1903 we paid £1,771 in salaries to assistants. This record should prove how little reliance can be placed on statements unsupported by the name and address of correspondents. As we have been established since 1879, it stands to reason that our experience of photographic assistants has been considerable, and while we are able to speak in terms of the highest praise of the bulk of them, we are bound to say we have met exceptions to the general rule, and have often been victimised by unscrupulous, dishonourable, and incompetent men. "Incompetent" assistants are common, and any firm endeavouring to maintain a high standard of excellence in their work must often have trouble with them. This class of assistant invariably has something to say to the detriment of his former employers, and no doubt many credulous people believe him. Another trait in his character is that he is generally unaware of his own incompetency. Directly he can take a photograph, or, having learnt the "stroke" of a retoucher sufficiently to ruin the "likeness" in a good negative, his arrogance knows no bounds, and he is (in his own opinion) a first-class man, good enough for any studio. If anyone doubts this, let them advertise in your journal for a "first-class" operator, and carefully analyse the replies. From remarks and correspondence received we find that the "spirit"

our humble contribution to your columns (for which you invented the heading, "Nothing Like Buttons") has been misunderstood. It is humiliating to have to explain that our "appeal" against the statement of our American correspondent, that "sooner or later we must become button manufacturers," was intended humorously. Gradually, next time we write anything of the kind, we must label our attempt, "This is a joke."

The second portion of our letter simply gave vent to our opinion that the practices of many professional photographers and others of these men do not turn out the crude specimens of portraiture you mention) were calculated to lower the tone of the profession generally, to bring it, in fact, into disrepute, and, by reflecting themselves and their work so cheap, create in the minds of the public a false idea of the commercial value of photographic portraiture. Obtaining the high profits "Argus" hints at out of women's at 8s. 6d. per dozen, must mean Sunday work, low salaries, and "sweating" for the employees. In proof of this, it is only a few months back that your paper contained an account of a "cheap" photographer who was fined for working girls long after business hours.—We are, gentlemen, yours faithfully,

MEDRINGTON'S, LTD.

Liverpool, October 18, 1904.

SOME PECULIARITIES OF DYES WHICH PRODUCE TOTAL SPECTRUM SENSITIVENESS.

To the Editors.

Gentlemen.—An article such as Mr. Wall refers to is necessarily open to much criticism, but that criticism need not be of the "biting" nature.

Mr. Wall states that a prolonged exposure to the spectrum of a plate bathed with wool-black shows an indistinct band from D to E; therefore this is the region to which the plate is least sensitive, comparatively. But this is the region of maximum absorption of wool-black. Hence my suggested law is proved!

Mr. Wall points out that eosin sensitises for the very region of its greatest absorption. That is precisely what my suggested law enabled, as I distinctly stated that with fluorescent dyes the reverse action was caused to that of non-fluorescent.

If only Mr. Wall would tell us something he has done that is original, instead of making quotation after quotation from the much overdone "German," what a treat it would be.

The Englishman likes originality and self-suggested research better than quotations, and I venture to think that Mr. Wall himself should think kindly of research, even if not carried out by a Valenta or an Eder, and even though he does not choose to follow or agree with the results.—Yours faithfully,

T. THORNE BAKER.

16, Rutland Park Mansions, Willesden Green, N.W.,
October 14, 1904.

THE KOENIG PROCESS.

To the Editors.

Gentlemen.—With reference to the article which appeared in your last week's issue in regard to Dr. Koenig's colour process, we now beg to hand you herewith full particulars of the process in question, including the working instructions.

Our Mr. Jules Fuerst has just returned from the works, and has seen the said process working, and the positive proofs which he showed you (one being a bunch of real flowers and the other being a living subject) were made in his presence.

To our mind there is no doubt that this process is a most remarkable invention of simply and economically producing positive images in natural colours.—Yours truly,

FUERST BROTHERS.

17, Philip Lane, London, E.C.,
October 18, 1904.

[The specimens shown us are excellent examples of the process.—Eds., B.J.P.]

HALF-HOLIDAYS FOR ASSISTANTS.

To the Editors.

Gentlemen.—Re Assistants' Half-Holidays. In reply to your correspondent's letter, published in your issue of the 14th inst., the Shop Hours Act, 1904, does not apply to workshops; these are fully dealt with by the Factory and Workshops Acts. These Acts have

large powers and mainly deal with women and children, and apply to a large number of photographers' establishments. The Shop Hours Act, 1904, deals absolutely with shops, therefore, the Act applies to all photographers occupying shops, and this will be welcome news to the many assistants employed by photographers. For once the shop is closed, business in the studio is, of course, brought to a close, thereby releasing many over-worked assistants, and, there is no doubt, many photographic assistants, employed by firms doing a cheap trade, work far too many hours. The Shop Hours Act cannot be too widely known, for it is an Act which leaves nothing to be desired, if it can only be brought into operation on behalf of the assistants, and there is no reason to suppose that the Early Closing Associations will neglect any time to ensure a speedy enforcement of the Act, which becomes law, I believe, next year. The expression "shop" under the Act includes any premises, or place, where retail trade (including the business of a barber) is carried on, and it provides for a closing order made by a local authority and approved by at least two-thirds of the occupiers of the number of shops to be affected, and confirmed by the central authority in manner provided by this Act, may fix the hours on several days of the week at which all shop or shops, of any specified class are to be closed for serving customers; shall not be earlier than seven o'clock in the evening on any day of the week, except that on one specified day in the week it may be an hour not earlier than one o'clock in the afternoon. The Act also provides that if any person contravenes the provisions of a closing order, he shall be liable on conviction to a fine of one pound for a first offence, and in the case of a second offence five pounds, and in the case of a third offence twenty pounds. The Act does not affect the sale of medicines, the sale of intoxicating liquors, and the sale of tobacco and newspapers. In conclusion, I should add that copies of the Shop Hours Act, 1904, may be obtained post free for three half-pence from Messrs. Eyre and Spottiswoode, East Harding Street, London, E.C.—I am, gentlemen, your obedient servant.

JAMES DENTON.

October 15, 1904

WE have received from the chairman of the committee of the American Photographic Salon at New York (Mr. Curtis Bell) a letter drawing attention to the great effort now being made to gather for the first time in America, a representative exhibition of the work of the world's great pictorial photographic workers. He says:—The greatest city in America—the centre of its art life—has never had anything in the nature of a photographic salon. Exhibitions of the works of a few masters have been frequent, confined to a limited number, and not open to the general public, but the fact that the general public is eager for such a treat has been proven by the generous support given this movement by the most cultured art lovers in America—support so unexpectedly liberal that it will be possible to make this the most important salon ever held in the world. One of the largest and most fashionable art galleries in New York city has been secured for the exhibition, and the attendance of that part of the public which gives practical encouragement to the artist is assured. Full particulars can be obtained from 100 and 102, West 101st Street, New York.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

Answers to Correspondents.

- * * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- W. Jeffery, 8, Spurlingate, York. Photograph of J. G. Butcher, K.C., M.P.
 F. J. R. Mac'adyen, 151, Barras Bridge, Newcastle-on-Tyne. Photograph of Lord Charles Cavendish.
 H. Pickering, 54½ High Cross Street, Leicester. Two Photographs of the Late Miss E. Vaughan.
 T. S. Robinson, 125 and 127, High Street, Homerton, London, N.E. Photograph of the Clapton Orient Football Team.

VIDEX.—Probably the Ilford Monarch would suit you.

GARRATT AND ATKINSON.—You will see that the correspondent, whose address we did not keep, was replied to on page 899 of our last issue.

BOOK WANTED.—"APPRENTICE" says: "I should be much obliged if you could give me the name and price of a good book on lighting." In reply: "Artistic Lighting," by Inglis, 2s. 6d.; "The Studio, and what to do in it," Robinson, 2s. 6d., are good books.

COLLOTYPE QUERY.—Mr. W. T. Wilkinson writes that the formula for substratum for colotype plate asked for by "Collo" (Leeds) in last week's BRITISH JOURNAL OF PHOTOGRAPHY is as follows:—Dextrine, 1 ounce; syrupy silicate of soda, ½ ounce; water, 10 ounces.

DEVELOPER.—"EBONY" asks: "Would you kindly oblige with a good developer which would give black negatives?" In reply: Any of the hydrokinone developers will yield negatives of a black tone, but if you want them dense you must leave them in the solution for a good time.

ANILINE COLOURS.—"ARTIST" asks: "Will you kindly let me know address of agent in London for aniline dyes?" In reply: The colours may be had from Hopkins and Williams, Cross Street, Hatton Garden. They are also kept by most drysalters and dealers in dyers' materials. We do not answer correspondents by post.

SENSITISING ALBUMENISED PAPER.—"ALBUMEN" asks: "Can you give me instructions as to how to sensitise albumenised paper?" In reply: Make a solution of nitrate of silver, fifty to sixty grains to the ounce, of distilled water, according to the amount of chloride in the paper. Float the paper on this for three minutes and hang up to dry.

COPYRIGHT.—EMERY AND SON write: "We sell some views of the town to a stationer, giving him full permission to reproduce them as postcards, etc. Does that prevent us selling prints of the same negatives to other stationers in the town for the same purpose?" In reply: No. Unless you agreed with the first stationer not to supply others in the same line of business.

TONING BROMIDES.—"TONING" asks: "Will you kindly say if you know of any good formula for toning bromide prints in quantities? We wish to obtain a brown or purple brown tone." In reply: Any of the usual formulae will do as well for toning large quantities as for small. You have only to use more solution. A formula was given in reply to "T. Charles" in our last issue.

COMBINED BATH.—"A. R. S." writes: "I should be glad if you would inform me of a really good formula for toning and fixing combined (one that will give a good black)." In reply: A formula for a combined toning and fixing bath is given on page 10 of the ALMANAC, which see. Combined baths are not to be recommended if permanency is a consideration, but the one given is as good as any other.

OPINION WANTED.—"L. M. S." writes: "(1) I should be extremely obliged if you would kindly pass your opinion on the end retouching, and can I say I can retouch? (2) Also would you give me a recipe for a good negative varnish?" In reply: The retouching is only fairly good; that is all we can say at present. (2) Several good formulae for negative varnishes are given on pp. 1063-4 of the ALMANAC, to which we must refer. They are all good.

REMOVING BLACK SPOTS.—"BLACK AND WHITE" says: "Will you oblige me with a recipe for removing black spots from prints. I am working black and white enlargements, and often retouching with superfluous black marks, which I should like to remove if possible without scratching with the knife." In reply: Small spots are best removed by scraping them away with a sharp penknife. Larger ones may be dealt with by an eraser. These are the best means for removing them.

COPYRIGHT.—"A. O. Y." asks: "Would you kindly inform me if a private individual can have a copyright photograph enlarged by an amateur friend (or by a photographer) for the purpose of completing a set of pictures for his own room and not for purposes of sale now or at any time? The photographer who enlarges the photograph cannot undertake to enlarge this print." In reply: If the picture is copyright it would be illegal to reproduce it in any form. As the holder of the copyright cannot undertake to make an enlargement, possibly he will give permission to do so.

PHOTOPHIL.—Either of the forms shown in your sketches are good, and it is very much a matter of opinion which is the better of the two. One carbon does burn away faster than the other, and all good hand fed lamps are provided with adjustment by which the crater can be kept in the axis of the condenser. We regret we do not know the address of the maker of the material in Germany. The only colourists we know of are those whose advertisements appear in our pages. We are afraid they will not be very successful in taking a hundred yards of strip with a single magnesium flash. You will, we expect, require several flashes at different parts of it—fired simultaneously.

STAINED PRINTS.—"J. A." says: "I finished a batch of prints at five nights ago, and most of them turned yellow. Last night I finished a batch of 56 prints, and took the utmost precaution with regard to the hypo coming near the washing water at fixing. Seven of them turned yellow and the rest were all right in some cases one of the prints from the same negative would be yellow, while another would be all right. Can you tell me the cause, as it is rather puzzling? Enclosed is one of the prints." In reply: We are surprised that anyone styling himself a professional photographer should be at all puzzled by such a simple thing as this. The prints were not kept moving while they were in the fixing solution. Hence some were (as might be expected) stained.

BRONZING OF SHADOWS.—J. B. PARNHAM writes: "The following questions were asked at one of our meetings this week, and were not answered in a very satisfactory manner. I shall be very glad if you can answer them for me: (1) What is the cause of the remedy for bronzing in shadows on self-toning papers? (2) Using slow bromide papers for warm tones by direct development how can you obtain the same warm tone on each print when doing a batch at a time?" In reply: (1) Papers containing a large amount of silver usually bronze when they are printed from strong negatives. The bronzing, however, usually disappears in the toning and fixing. (2) Simply giving all the prints the same exposure, and removing them from the developing solution as soon as they assume the desired colour.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

The forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The growth in popularity of the ALMANAC is evidenced by the remarkable rapidity of its sales.

The 1900 Edition (20,500 copies) was sold within three months after publication.

The 1901 Edition (20,500 copies) was sold a fortnight after publication.

The 1902 Edition (20,500 copies) was sold a fortnight before publication.

The 1903 Edition (25,000 copies) was completely ordered before publication.

The 1904 Edition (25,000 copies) was also completely ordered before publication.

** The frontispiece of the ALMANAC will consist of a portrait study specially taken by Mr. Furlley Lewis (medallist of the Royal Photographic Society's Exhibition, 1903).

EX CATHEDRA.

Sensitive Test for Gold. We have had brought to us for examination samples of combined toning and fixing solution containing no gold, and self-toning paper represented to be made with the assistance of gold which contained not a trace of the precious metal, so far, indeed, as the ordinary modes of testing could reveal, though whether, "to save the face" of the maker, an infinitely small quantity may have been put in or not, we are not prepared to say; but even an amount which might justly be included under such a term appears now to be capable of detection. Herr J. Donan, in the proceedings of the Vienna Academy of Sciences, describes a method which he has devised which is capable of revealing the presence of so small a proportion as the five-millionth of a gram. A fibre of silk or wool is treated with a solution of tannin, or a solution containing pyrogallol and stannous chloride, and then immersed in the acidified solution to be examined for gold. If any be present it will be precipitated in the colloidal form on to the fibre, to which it imparts a red coloration which is observed by examining the fibre under the microscope.

* * *

Injuries by the X-rays. It will be remembered that a fortnight ago we chronicled the death of one of Mr. Edison's assistants in his fluoroscope experiments, after seven years' torture resulting from exposure to the X-rays, and the symptoms were described. Now we learn that Mr. Hale Edwards, of Birmingham, whom many of our readers know is one of our leading authorities on the X-rays, is suffering badly from dermatitis, brought about by continually working with the Röntgen rays. His hands, it is stated, are fearfully disfigured, and almost entirely covered with a kind of wart. The nails are black and the skin coarse and dry. It appears there is no specific remedy for the disease, and the only thing to be done is to abstain from using the rays. Sir Oliver Lodge has expressed the opinion, so the report says, that the rays themselves are not responsible for the trouble, but something which accompanies them, and which can be screened off by suitable appliances, whereas no screen will completely obstruct the rays. But from the report now before us no mention is made as to what are the "suitable appliances" that can be used to screen off the injurious "something that accompanies" the rays from the operator. It is said that the only remedy for the trouble is to refrain from working with the Röntgen rays and things will right themselves. This, it may be mentioned, is the only remedy in some cases in connection with photographic operations—working with the bichromates, for example. Some in working the carbon process continually have suffered badly from the bichromate, and there appears to be no specific for it. But

if the work be relinquished the disease soon cures itself. The same with metol. That acts injuriously on some, and for that there seems to be no actual specific. But let the metol alone and things right themselves in a comparatively short time.

* * *

A Modified Lippmann Process.

Photography in colours seems rather in the air at present, and notable improvements and modifications of existing methods are being brought forward with justifiable hopes that an era of improvement has begun. Among these may be noted a simplification of Lippmann's well-known process, of which we have not heard much of late, though the probabilities are that we may, if M. E. Rothé's process recently expounded at the Paris Academy of Sciences should prove to be a success. It will be scarcely necessary to remind our readers that the Lippmann process is founded on the photo-development of light-wave interference effects within the film, brought about by reflections from a bath of mercury in contact with the film, the metallic surface reflecting the spectrum, or other colours, thrown on the sensitive surface through the glass. To apply this mercury backing special appliances are naturally required, and the process is only attempted by those who are provided with the needful arrangements which are not such as can be readily extemporised. M. Rothé, after a careful examination of a number of the usual kind of Lippmann photographs, was led to the conclusion that a bath of mercury was not essential, and that the air reflection ought, if a sufficiently prolonged exposure were given, to be able to bring about the requisite interference phenomena. He put his theory to the proof, and found it was correct. The great advantage of the Rothé method is that no special material or apparatus is needed. *A priori*, we should have thought that the initial action of the impinging light would be so great as to nullify any within-film effect of interferences; but we record the account of the method which was read before the Paris Academy of Sciences on October 10 last.

* * *

Picture Post-cards and the Post Office.

Although the picture postcard has become such a universal institution, there is evidently misconceptions in some quarters as to what really constitutes a postcard according to the regulations of the Post Office authorities, for the Postmaster-General has found it necessary to issue a circular drawing the attention of publishers and the public generally to the regulations governing the transmission of postcards in the inland service. As these may be of service to some who publish cards of local views, and produce them themselves, we here reproduce the regulations as given in the circular. "Cards intended for transmission as postcards within the United Kingdom may not exceed $3\frac{1}{2}$ in. in length or $3\frac{1}{2}$ in. in width, or be less than $3\frac{1}{4}$ in. in length or $2\frac{1}{4}$ in. in width. They must be composed of ordinary cardboard, not thicker than the material used for the thickest official postcard, and not thinner than the material used for the thinnest." If any of these and other rules be infringed, the card is treated as a letter liable on delivery to surcharge. These regulations should be kept in mind by those photographers who publish postcards, or the purchasers of them will subject their friends to whom they are sent to an extra fee on delivery. It does not seem to be so generally known to many that nothing must be attached to a postcard. A photograph must not be mounted on a postcard, even if its entire thickness, when mounted, does not exceed that of the official thickness; but the photograph may be printed direct

on the thickest. While on the subject of postcards, it may be mentioned that according to a Berlin correspondent petition is to be presented by a committee representing Berlin commercial circles for the introduction of postcards on the front of which communications may be written similar to those used in England. At present, if an ordinary postcard be written upon on the address side and sent abroad the recipient is surcharged as if it were a letter. This has frequently been the case when friends here have, through ignorance of the rule, written on the address side of picture postcards.

Reflections in Water.

Sir Montagu Pollock, Bart., has recently produced a book bearing the above title, and our contemporary "Nature" a week or two ago gave an illustrated review of it. The work is notable for the number of excellent photographic and other illustrations it contains, one very singular example being reproduced in the journal named, besides a very effective ripple effect. Visitors to photographic exhibitions who have made a study of this subject have often been amused by apparently photographed reflections in water shown in the photographs, reflections which they could tell at a glance were only fictitious, having been printed in, possibly with artistic judgment and intent, but without knowledge. A study of Sir Montagu's book would enable the reader to avoid all such pitfalls, though, as a matter of fact, the photographer is not alone in committing these errors, many artists being sublimely indifferent to such scientific matters as the correct reflection of objects in water. As "Nature" says, "Sir Montagu Pollock has entered an almost untrodden region, within the border of both art and science. With the exception of some passages in the works of Mr. Ruskin, it would be difficult to refer to any other work dealing with the same subject. . . . although the book was written to aid artists in their study of nature, it will none the less be welcomed by men of science and those amongst the general public who attach importance to accurate observation." As we have said, photographs with pseudo-reflections, which, by the way, when efficiently made, require far more knowledge than the mere printing-in of clouds—too often a trap for the unwary—have been exhibited; but, on the other hand, there have been shown other entirely unsophisticated photographs, with genuine reflections, which, nevertheless, have been so peculiar that a very general cry has been raised against them. The example referred to above would, if exhibited, have been placed in this category, for the foreground of the picture—if the term "ground" may be applied to a sheet of water—composes so effectively, yet is so peculiar that the observer would almost involuntarily exclaim "faked!" when he first saw it. Before dismissing the subject, we desire to say that we must not be taken in by inferring that perfect reflections of objects in a sheet of water are, as a rule, desirable pictorially. So far is that from being the case that we unhesitatingly say that, as a rule, the more perfect the reflections in the water, the more atrocious to the artistic mind is the effect; and our concluding advice in treating such subjects is: "Immediate before uncapping the lens throw a stone into the water break up the reflections and prevent their being 'perfect'."

AWARDS at the St. Louis Exhibition.—Gratifying evidence of the recognition extended to British commercial enterprise is furnished by the honours awarded by the committee of the St. Louis Exhibition to Messrs. Burroughs, Wellcome and Co., the manufacturers of "Tabloid" photographic chemicals. Three grand prizes and three gold medals have been conferred for the scientific excellence of their products.

THE IGNORANCE OF SOME PHOTOGRAPHERS.

draft prospectus of the P.P.A.'s scheme for granting certificates (published in last week's JOURNAL) calls to mind in a forcible manner the depths of ignorance in which many photographers flounder. We are principally, of course, to lack of theoretical knowledge, which, however, is of the greatest use in practical work. Of course, with the present state of photography and the simplicity of all processes connected therewith, it is for a man to be a good photographer and yet not know anything of his business outside his own particular sphere. We note that the P.P.A. recognise this, and their scheme is baldly practical, and we think no one will attack it on that score. At the same time we should like every photographer to make as much progress as possible with photographic theory, for without at least a smattering of it it is almost impossible to reach the very top-pinnacle of photographic excellence.

If one glances through the columns of this JOURNAL—and we think we are safe in saying that a great proportion of its readers are professionals—one cannot help noticing a variety of questions which are asked and answered. It is not the variety, however, so much as the quality that strikes one. By this we mean not only the puerile simplicity of many of the inquiries which almost any textbook could answer, but also the meagre details which are at times given as a clue to the unravelling of some intricate inquiry, showing how little the correspondent knows of the materials he handles. This charge of ignorance, however, is by no means levelled at the heads of amateurs, looking them as a whole, leaving out the mere button-pushers who don't do the rest, and whom no one takes seriously, the serious amateurs, as a body, are better versed in photographic theory than many professionals. Of course, one does not expect the working professional to waste time and money over experimenting, but certainly he should know the rudiments of his business. It is certainly no use for us to clamour for photography to be included among the professions whilst the present state of affairs exists.

Apparently any one who has a camera and can make a fair guess at exposure and developing thinks he is entitled to practise as a photographer if he cares to, without the slightest reference to textbooks or even general education. How far the proposed scheme of examining assistants is likely to help us no one can say, but it is certainly a step in the right direction; but nothing but the somewhat utopian scheme of compulsory examination for employees can really advance us towards the higher goal which the better class professionals look. And that is the worst of it. Really good men have some right to consider photography a profession, for in their case expenses of materials are almost nil when compared with the price charged. As with the professions, their fees are for brains, not materials—not only the brains put into each photograph, but also the brain-work expended on reading up and getting to know their work thoroughly before practising. On the other hand, the dozen for 12s. 6d. men and the twelve a shilling persons are content with a slight percentage on their material, and have certainly never expended time, brains, or anything else on improving their knowledge of that which in some hands is not only a profession, but an art. As there is at present no dividing line between the two—the qualified and the unqualified—the perennial question of profession or trade is further complicated.

We opened this article with a reference to the general ignorance existing among many photographers, and an easy method for the reader to find out for himself—viz.,

the correspondence columns of a professional or semi-professional paper; but this doubtless in the majority of cases will be unnecessary, for any professional with a fair knowledge of his business must be always coming across instances.

For ourselves, we know of an operator of ten years' experience, good in his rule-of-thumb way, who is unable to calculate the ratio of exposure required by different stops. Say he is certain one second at F. 6 is right and F. 32 is required. Instead of doing the necessary calculation, which would perhaps take five minutes to learn and a fraction of a second to practise, he guesses.

Then again, when copying photographs, how many workers know exactly how much to increase the normal exposure by measuring the difference between usual position of focussing screen and the position occupied when taking that particular copy, or when enlarging, can they tell how much exposure is increased or decreased by the movement of the sensitive surface nearer to, or further from, the lens? In other words, is the simple rule that exposure varies in inverse proportion to the square of the distance of the sensitive surface from the lens at all well known? Practically the same rule as applied to bromide-printing—viz., quadruple exposure, as distance from illuminant is doubled—is better known.

These few simple points are doubtless called theoretical knowledge, and on this account are unknown to many workers; yet how greatly they simplify and make more certain every-day work!

Then, again, to take just one process—viz., the collodion-chloride—and glance through the various stages, and note where a little chemistry will help. The washing should be longer than for albumen prints. Why? Because, whereas albumen contains only free silver, C.C. has preservatives combined therewith, and these preservatives take longer to dislodge than the silver. Why should prints be washed between gold and platinum toning, and also why should separate dishes be used? Because gold precipitates platinum, and any free gold in the water or on sides of dishes would make muddy prints, and lead to great waste of platinum, besides the alkaline gold being liable to neutralise the acid in the platinum. Platinum must be acid, because it will not tone if alkaline, neither will gold tone so well if acid. Why is thorough washing after platinum necessary? Because any trace of acid in the hypo leads to sulphur toning, and therefore the acid platinum must be got rid of. And so on and so on. We could go through other processes in a similar way; but enough has been said to show the value of simple and easily acquired knowledge.

Another instance of ignorance which has come under our knowledge is the case of a high-class (price) professional who has only just learned what tone is—that is, of course, apart from its meaning of colour.

As for general education, only recently we were present during some exposures on an M.P., and one of the leaders of the Liberal party. A middle-class professional was also present. Here is a sample of his speech: "Just a moment, Sir 'Enery." But those examples are quite enough, and, we fear, far from uncommon. Before professionals can hope to raise the standard of the profession they must see to it that they at least learn the elements of their business. This should do more than any examination scheme, though I certainly hope and think that that is several steps onward.

The scheme drawn up by Mr. Dundas Todd on the other side of the water should also be keenly watched, and we are sure that if there is any good in it and any advancement on the upward grade, our own Photographic Association will advocate something similar.

In conclusion, all those who have the welfare of what is an honest, and should be a respectable, profession at heart should strengthen the hands of this body with their subscriptions, and, more important still, the moral weight of their membership.

TECHNICAL SCIENCE IN GERMANY.

MUCH has been written in this country about the encouragement given by the Government to technical science in Germany and the comments made upon its alleged neglect here. Attention has also been called to this subject in America by the American Consul-General in Berlin (Mr. Mason), who has just forwarded a long report to his Government pointing out the great influence exerted by science on the industrial development of Germany. In his report Mr. Mason particularly refers to the chemical industry as a case in point. He mentions that chemicals amounting to over 60,000,000 lb. are produced annually in Germany, thanks to chemists who, though they have received a University training, are willing to work incessantly for moderate salaries in the laboratories of the chemical manufactories. This is an important statement and one that might well be taken to heart in this country, where chemists, as a rule, demand very substantial salaries, particularly when they have received a University training. In the report mention is made of the fact that the aniline industry had its origin in England, but it was taken up by Germany, which now manufactures four-fifths of all the dyes and the greater part of all pharmaceutical preparations produced from coal tar. When the aniline industry was first commenced enormous works were erected at Greenford, near Harrow, and a very lucrative business was carried on there for some years, but, owing to German competition, it became lost, and when we passed the works a few years ago they were in a complete state of wreck and dilapidation. The report further shows that in 1892 Germany imported over three million and a half pounds of indigo. In 1897 Dr. Bayer discovered artificial indigo, and as a result the value of real indigo imported fell from about £900,000 in 1892 to £160,000 in 1902, while over 9,000 tons of synthetic indigo were exported in the same year. This is not pleasant reading, seeing that some of our Indian possessions are largely dependent upon the growing of indigo. Commenting on the American Consul-General's report, a correspondent, Mr. Bryan, University, Bangor, in a letter in the *Standard* one day last week, makes some remarks on the statement that German chemists work incessantly, and for moderate salaries, in the chemical manufactories, and says that we have here numbers of mathematicians, physicists, chemists, etc., who have taken the highest honours in the Universities who would only be too glad to earn a very moderate salary in the development of our national industries. But he adds (and we fear there is too much truth in what he says) "the control of these industries is in the hands of practical men who will have nothing to do with the scientific expert, and will not accept his discoveries or suggestions, even as a gift." In concluding his letter, Mr. Bryan says:—"There is no man so unpractical as the typical British 'practical man.' He persists in employing processes and turning out goods which the smallest grain of common sense shows to be defective. The quality which he values most in his assistants is mediocrity as opposed to real ability. Therefore, let him not grumble at having to take a position of mediocrity in the commercial world." As we have just said, there is much truth in what the writer says, but there are works in this country we know where expert knowledge is largely and profitably availed of, though not perhaps to the same extent as it is in Germany.

PROGRESS IN ENLARGING.

[A paper read before The Royal Photographic Society.]

WE may consider the lightest tone, either in a subject, negative, or a print, as the top of a slope, whose base is the darkest tone, and the positions between them the intermediate tones; further, by simply drawing a line to represent the slope and giving actual values to the space it occupies, we can represent any series of tones, whether sudden, steep, or delicate.

Fig. 1 represents in this manner a uniform gradation of tones, from black to white, across a quarter plate and a 16-in. print respectively. It illustrates in a simple manner why the

FIG. 1.

size of a print exerts such an important influence on character, and why enlarging so greatly increases breadth.

Equally well, a line will directly illustrate, by its upward or downward direction, and by its character of slope, curve, or step, the range of tone and value of the tones in any subject, negative, or print.

It is found with any particular printing paper and process that a certain fixed range of tone is required in a negative, all its gradations are to be impressed on the paper. To illustrate clearly what is meant, I have here a sample of bromide paper which has been exposed to light, so that we get a series of tones from black to white. To darken this paper black required 16 times the exposure necessary to tint it the lightest tone, which is only just distinguishable from white. It is evident, therefore, that any range of tone in a negative greater than this will only be partially rendered on the paper, as a longer exposure than 16 times cannot make the black paper any blacker, and any exposure less than the one does not produce any visible darkening whatever. In the ordinary practice of enlarging, it is necessary for this reason that the range of tone in the negative must not exceed about 16 to 1, if it is required to preserve gradation in all parts. To compare with this sample of bromide paper, I have also a sample each of P.O.P. and carbon paper similarly exposed, and they illustrate that for the one we require a range of tones in the negative of 1 to 64, and in the other (the carbon) a range of 1 to 256.

We require, therefore, to preserve gradation in the three processes, three different negatives, one for each.

Suppose it is required to produce an enlargement from a negative having a range of 1 to 64.

FIG. 2.

a, a, a, in Fig. 2, represents, by means of the slope, a gradation from 1 to 64 in a negative.

b, b, b, illustrates the loss of gradation when a short exposure is given for the enlargement.

c, c, c, represents the loss of gradation with a mean exposure.

d, d, d, represents the loss of gradation with a full exposure.

The point to notice is that with any exposure gradation

and black or white, or both, substituted, and the print, fully developed, has the well-known hard or chalky appearance.

[This example illustrates the position we at the present day occupy in regard to the conditions essential to successful enlarging, and assuming a subject which is perfect in itself; if we require an enlargement which is also perfect, two accurate adjustments must be made.

I. The development of the negative to the proper range for enlarging.

II. The correct exposure and development of the enlargement. I have not included the exposure of the negative because there is fair latitude in this respect).

In the great mass of work which is daily forthcoming errors in these adjustments produce the majority of failures or defective prints.

Suppose in a given case, having already found that a hard print lacking gradation is produced, we make a fresh enlargement, and, before the exposure is made, place in contact with the paper a photographic positive of a process screen, so that the two films are in contact. Wherever the opaque parts of the screen protect the bromide paper, it will remain more or less unaffected, and all the tones of the print will in consequence be lighter in proportion to the relative area of the opaque and transparent portions of the screen. A soft print is now obtained, which may be much more pleasing than the one without the screen; you can also vary the softness at will by placing a sheet of glass of suitable thickness between the screen next the paper, and varying the aperture of the stop, the action being due to a greater or less spreading or vignetting of the light after passing through the apertures of the screen, similar to that which takes place where the screen is used for process work. In all these cases, however (except in a particular to which I will refer presently), the range of the tones between which the gradations are reproduced will be less than when the screen is absent, in proportion to the percentage of light intercepted by the opaque portions of the screen, so that while the black-and-whiteness has been corrected, the loss of gradation remains, and the result is substantially similar to that obtained when the print is softened by variations in the exposure and development; no great advantage, therefore, would appear to result from the use of the screen.

Three years ago, while testing some supposed cases of halation, I became aware that something very different from either film or reflected halation was taking place, and that that something was irradiation. The conditions of this effect are more fully treated in the paper which follows on colour photography; it will be sufficient to mention here that irradiation occurs in nearly all photographic processes—that is, the action of light on a sensitive film, when it takes the form of a line or dot, spreads laterally with a sharp outline, in a similar manner to the apparent thickening of an electric lamp filament on the retina. In the former case the spreading increases with the exposure, in the latter with the brightness, the degree of spreading for a given increase of exposure depending upon the physical character of the film, and the optical constants of reflection and absorption. Owing to this action, by simply increasing the exposure a print can be obtained with full range from black to white, although a screen is placed with its film in contact with the paper, but (and here is the pith of the whole matter) the range of exposures required to produce black and white is much greater than that which produces black and white in the ordinary manner when the screen is not used. Therefore, when employed in conjunction with a screen, a negative may be said to possess any working range of tone, according to whether you work on the irradiation device or on the ordinary pure tone, or partly on each.

This being so, on taking a negative with a range of 1 to 64

or 1 to 256, we can at once adjust our procedure to suit the negative, and obtain an enlargement with perfect gradation, and any degree of softness, equally as well as with a negative specially developed for the particular effect required. I have here a portrait of a girl, and numerous other technical examples of enlargements produced in this way.

Let us now turn to the second adjustment, that of correct exposure and development of the bromide paper. The screen gives enlargements in which the tones are formed by minute dots differing in size, the space between the dots remaining comparatively unaffected, and we have also the effect of lateral spreading with increased exposure due to irradiation. This means, in fact, that the conditions are similar to a multiple coated plate, with a corresponding increased latitude in the exposure. For the reason also that all the dots are equally black or nearly so we remove the necessity for exact development; you cannot make a dot blacker than black, and so minutes more or less either in exposure or development become unimportant, and, even if overdone, prints can be reduced with facility without injury to the most delicate gradations.

The screen, therefore, removes the necessity for exact adjustments in exposure and development; at the same time we have by no means exhausted the advantages which its use confers. If you take a sheet of bromide paper and expose it in the enlarging lantern without the intervention of a negative or through a flat tint developed on an exposed plate so that the paper should show a flat tint on development, it will be found that the tint is always somewhat mottled or uneven; this defect at once disappears when the screen is employed, and in addition a degree of transparency or richness is imparted due to the screen texture.

Again, when starting with the supposed negative giving a hard print, it was assumed that the gradations of the subject were perfect, and the aim was simply to reproduce it properly as an enlargement. But in how many subjects are the gradations of lighting perfect; are they ever perfect? Take the case of a simple object such as a sphere. I have tried every possible device to illuminate this sphere, and get a photograph showing perfect sphericity; daylight, arc light, incandescent light, diffusers, and reflectors—with all or any of them result is defective. I have here an enlargement from such a photograph (5); alongside this defective print is one made with the assistance of the screen, a perfect sphere at once being created. What is true of this simple piece of shading is also true of complex cases.

Fig. 3 illustrates a common case where difficulties arise.

FIG. III

a, a, a, a case where the general character is satisfactory, but the gradations are broken up into local differences.

b, b, b, the same, treated with a screen.

And yet again, we have been assuming that the plates used for making negatives are always perfect, or nearly so, as regards their capacity for recording gradations, and that camera exposures are always accurate, but in practice we know this is not the case. Fig. 4 illustrates a subject which, through having a long range, shows under-exposure in the shadows and over-exposure in the high lights.

Please do not think I am endeavouring to show that picture-making is to become automatic; this will always depend, as it does now, on the taste, industry, and skill of the operator; what I am wishing to illustrate is that the optical conditions for success can be simplified and improved, that vexatious elements of uncertainty no longer exist, and that, by taking advantage of a simple optical device, you can employ it in moulding to your wishes the qualities of negatives and prints. A little practical experience with the screen on the part of individual workers will convey to them its remarkable influence and resources. It is possible some one may object to the use of the screen on the score that, having only seen its results when employed for process work, they will be prejudiced against its use in pure photography; if there be any such here, I would ask them if they have any fault (due to the presence of the screen) to find with the specimens they have before them; in all these specimens a somewhat coarse screen has been employed, 133 lines to the inch. I need hardly say that any degree of fineness can be used, and any kind of grain, lace, muslin, asphaltum, etc., the only essential conditions being the breaking up of the image into lines or dots. All the desirable qualities of a print are, as a matter of fact, improved by the

FIG. IV

a, a, represents the gradations of an ordinary enlargement from such a negative.

b, b, the same where a screen is used.

screen—greater delicacy of gradation, greater purity of tone, and a better texture.

There is one point on which I would solicit co-operation. The word "screen" being so widely used to indicate its employment in process photography, we require to distinguish it when used in the manner indicated to-night. I have, for this purpose, taken an analogy from gardening; if a man buys a piece of land to make into a garden (a large garden), the first thing he does is to grade the land, which means that he removes all the little irregularities, and connects the different levels by graceful slopes; this is exactly what the screen does in enlarging. I call it, therefore, in this connection, a "grader," and its employment the operation of "grading."

I have referred solely to the application of the grader to enlarging, because it has already proved its practical utility for such work by tests extending over the past two years, and is now in daily use at the Polytechnic. In its nature, however, it goes far beyond enlarging, and it has already received a most valuable application in colour photography. I reserve for a future occasion some further developments.

HOWARD FARMER.

HULL Photographic Society.—On Thursday, October 20th, Mr. Dyson (a member) demonstrated the carbon process before a large attendance. He proved its simplicity, and could not understand why so few took it up unless it be the mistaken idea that it was difficult. Quite a number of prints were developed, and the water was simply as hot as the hands could bear, doing away with the keeping up of the temperature, which he never troubles about. At his hands it was not necessary to use weights, except, of course, for supports, to keep in contact. There must have been many converts to a beautiful, certain, and permanent process. He used a sponge to develop, which was effective.

THE TESTING OF ORTHOCHROMATIC PLATES.

[A paper read before the London and Provincial Photographic Association, I.]

It is always much easier to find the faults than the good points in anything, and I am afraid, when I finish my notes, you will think that all I have done is merely to find fault; but I would ask you to believe that, at any rate, my intentions are good even if the execution is bad.

The subject which I have chosen is an important one, and important for two reasons: Firstly, if photography as a reproductive art is to improve, one of the directions must be in the improved rendering of colours in monochrome; and secondly, the use of colour-sensitive plates has so much increased of late that greater attention has been paid to them, and, consequently on this, we have had many papers dealing with the testing of the same which, in my opinion, call for some comment—a comment of rather a strong nature.

In the first place, I would like to call attention to the extraordinary increase in the number of spectrograms which have been put forward from various sources as proving the colour sensitiveness of this or that plate, some obviously from ignorance, and others for trade purposes.

We all know that the average testimonial is not worth the proverbial "tinker's dam"; there is no manufacturer who can not produce these by the score. But the matter is different when we come to papers published in our journals, or read before important photographic societies, and which, thus, in many cases, bear the imprimatur of an authority which they do not deserve, and which are subsequently used by others for advertisement purposes. This is a procedure which is, at least calculated to restrain any one who has any self-respect from naming any commercial preparation in a paper, which is, I think, a result not conducive to general knowledge.

I am afraid my notes to-night must be taken as a strict indictment of the present method of testing orthochromatic plates, and I propose to quote from various sources in support of my views, and would only explain, in self-defence, that my opinions were formed long before most of these papers appeared. (As a matter of fact, I objected to the current method of ortho-plate-testing in 1893), and, although I have long been dissatisfied, both from the practical and scientific side, with the method of testing ortho plates, I have not hitherto seen any way clear to suggest anything better.

I would first call attention to a note by Dr. Neuhauss in the "Photographisches Centralblatt," July, 1904, pp. 187-188, where he says, when treating of the colour sensitising of a Lippmann emulsion: "With all the plates the blue, violet, and ultra-violet zones appeared by far the quickest. . . . In order to obtain usable coloured camera exposures, we must, therefore, insert a yellow filter, which only transmits a third of the blue and violet light. . . . Under these conditions results will be obtained by Lippmann's process which will reproduce all the colours of Nature in an excellent manner. . . . If a plate sensitised with cyanine, erythrosine, and glycin-red, and exposed to the prismatic spectrum, be developed, the deposit of silver from the red to the violet appears absolutely equal. From this the conclusion must be drawn that the plate possesses equal sensitiveness for all colours. We have seen above that this conclusion is false, for the plate has at least three times too great a blue and violet sensitiveness. The prismatic spectrogram thus gives rise to a fallacious conclusion of the worst kind. Would that these facts were more generally appreciated. The expert can naturally make a correct deduction of the colour sensitiveness of the plate from the results obtained with the prismatic spectrum. When, however, as happens every day, spectrograms of this kind are published in journals destined for lay readers, there is again caused in wide circles quite false conclusions over the actual sensitiveness of the plates. To the

plate-makers this may be agreeable, but 'the man in the street' has no advantage from it."

This is the comment of an expert, and, whilst dealing with the Lippmann process primarily, it is obviously of general application, and is intended to be so applied.

Again, in "Photography" for August, 1904, p. 125, there appeared a paper entitled "Orthochromatic Exuberance: An Unorthodox View," by Chas. S. Dyer, the opening sentences of which ran as follows:—"It is a fine euphonious term—orthochromatic; it seems to lend a kind of distinction to the user, spreads a sort of academic halo round the subject, and adds a philosophic grandeur to the whole business. Perhaps this may have been of some influence in the present avalanche of claims on behalf of the colour-sensitive plate. Who knows? Why use orthochromatic plates for general purposes? The usual answer is that they give better colour values. My reply is that, if used without screens, they do not, in most cases, make any practical difference. Now, of course, in their own special lines and with light filters, they are invaluable; but to advocate their use in and out of season, and for all and every purpose, is really going too far. I humbly raise a solitary protest against the present flood-tide of intemperate eulogies made on their behalf. Their indispensability, with screens, for copying many pictures, for photo-microscopy with ordinary objectives, for tri-colour work, and photographing mixtures of blue and yellow flowers, is patent enough; in fact, in the case of the latter subject, the tests of orthochromatic plates show a tendency towards correct values even when they are used without screens. But, apart from that hackneyed blue and yellow flower mixture, which is pushed for all it is worth, the difficulty is to find any general subject in which they show the slightest appreciable effect, and, still more, one in which the marked benefit is obtained by employing them screenless. The results of exposing orthochromatic plates to the Chapman Jones tester seem to show wonderful efficiency. Better results have been got from the spectrum itself. But, when exposing the same plates to any average subject, the expectations raised by those tests are not borne out to any satisfactory extent. Nature's colours are, apparently, not so spectroscopically pure." I will not quote the rest, for I do not agree with all that was said by the author. This extract is enough for my purpose, and, without being rude to Mr. Dyer, I may say that this is practically the view of "the man in the street."

Again, in "Photography" for May 28, 1904, Mr. Arthur Payne, F.C.S.—who is, I believe, one of the chemists of Messrs. Mawson and Swan, the well-known dry-plate makers—says: "Considering the reliability of these various methods in the above order, sensitometers made after the pattern introduced by Warnerke are liable to give false results, because the absorption properties of the graduated deposit may introduce so large an error as to make the results entirely misleading; and, as the colour sensitiveness of the various plates is of so varied a character, this error cannot be easily compensated. The consequence is that the deposit acts as a light filter, and lowers the speed of the plate which possesses the least colour sensitiveness, and, when this happens to be an ordinary plate, the error introduced is considerable. If two plates of relative equal colour sensitiveness, but of different speeds, be compared, the error is not great; but when one of these plates possesses a stronger colour sensitiveness than its opponent, then the latter is placed at a serious disadvantage; for though the speed of the former plate is not increased by means of this sensitometer, yet it is apparently so, for the speed of the other plate is lowered below its actual value. In support of these statements the writer may quote the results of a series of tests he recently made, using a pattern of this class of sensitometer which is in favour at the present time, and in which the graduated deposits are of varying thicknesses of pigmented gelatine of a brownish black colour. An ordinary plate and a colour-sensitive plate were exposed behind this sensitometer

to the light of a standard candle. The plates were subsequently developed together with pyro-soda without bromide, and the result of a series of tests showed that it was necessary to give thirty times the exposure to the ordinary plate that was necessary to obtain the same result upon the colour-sensitive plate. Thus, by this method of testing, the colour-sensitive plate was thirty times more rapid than the ordinary plate to candle light. Two strips of similar plates were exposed simultaneously in the H. and D. exposing apparatus to the light of a standard candle; they were then developed together with the H. and D. standard pyro-soda developer, and, upon measuring the densities in the photometer, and plotting the curve upon the chart, it was found that the colour-sensitive plate was 5.6 times more rapid than the ordinary plate. In this method of testing there is no medium, except air, between the sensitive film and the source of light. Further tests were made by daylight, with the following results, in which the higher number represents the greater speed:—

Plate.	No. 1 Pattern Sensitometer.	No. 2 Pattern Sensitometer.	Camera Test.
Ordinary	1	1	1
Colour Sensitive	6	2	2

The sensitometer tests were exposed to daylight reflected from a sheet of white blotting-paper, and the camera tests were made upon a portrait. There was no medium interposed between the source of light and the sensitive plate in Spurge's sensitometer. The Warnerke type of sensitometer must consequently be avoided for this class of work."

Those of you who know Mr. Payne's book on "Orthochromatic Photography" will the more readily give weight to his words. To those who do not I would say read it, and they will at once appreciate the value of the quotation.

We have thus the remarks of Dr. Neuhauss on the spectrogram, Mr. Dyer on the spectrogram and the Chapman Jones plate-tester, and Mr. Arthur Payne on a sensitometer which he does not name, but which most of us can guess at.

I now propose to quote Dr. Eder. I can imagine some of you thinking that it would be a wonder if I did not quote him. My excuse is that he has a recognised position as one of our first experts, and has paid particular attention to the whole method of plate-testing, and in his work, "Systeme der Sensitometrie der Photographischen Platten," 1901, pp. 129-130, he says: "The total sensitiveness of orthochromatic plates compared to that of ordinary plates to white light—such as daylight, or the approximately similar, but not identical, arc light—cannot be estimated without considerable doubt from their total sensitiveness to candle light. It does not therefore, appear practical to give the sensitometer sensitiveness of ortho plates for the amyl or benzine lamps, when the numbers will be used for estimating the exposure by white light, such as day or arc light. The following table will show how the relative sensitiveness of an ordinary and ortho plate varies to the amyl-acetate and white light:—

	Amyl Light, Direct.	White Paper, Illuminated by Arc Light.
Ordinary Plate	1	1
Erythrosine Plate	2.3	1.27
Commercial Iso Plate A.....	1.6	0.67
" " B.....	1.2	0.42

As will be seen, it may even happen that, with the amyl light,

the ortho plates are more sensitive than the ordinary, whilst with the electric light the reverse is the case."

Again, in a paper by the same author, published in the "Photographische Correspondenz," 1903, p. 426, entitled "Ueber die Sensitometrische Prüfung Gewöhnlicher und Orthochromatischer Platten," or "On the Sensitometric Testing of Ordinary and Orthochromatic Plates," there occurs a table from which I make two extracts, and two only, because they deal with plates on the English market:—

	Benzine Light.	Daylight (Equal to an ordinary Plate).	Blue. Yellow.		
			Benzine, Direct.	White Paper.	
				Day.	Mg.
A Plate	13° S.	11—12° S.	1 1·3	6—7 1	4·3—5 1
B „	12° S.	9° S.	1 1·3	11·3 1	4·9 1

I have purposely suppressed the names of the plates, but an examination of the table is striking as regards the value of the light in testing, and the method employed is practically Hurter and Driffield's.

I stated that I had picked out these two plates because they were on the English market. There is another reason why I signalise these two plates, and that is that they happen to occur in a list of plate speeds given by Messrs. Newton and Bull in a paper read before the Royal Photographic Society in October last—a paper characterised by a wealth of detail, and showing evidences of the most careful and painstaking work, and one which is simply invaluable if read from the point of view of the authors—namely, that it was a record of particular batches of plates tested by a particular light and a particular method—but absolutely misleading when used, as it was, for advertising purposes by some one, or if used as a guide for outdoor work.

Now, these two plates were stated by Messrs. Newton and Bull to possess a certain ratio of speed, and I have converted their numbers into Dr. Eder's numbers, with the result that, as the latter gives the relative speeds of these two plates to artificial light as 18:14, Messrs. Newton and Bull give the speeds as 18:5½, whereas, by daylight, the speeds were as 14:7. When the relative speeds to blue and yellow are considered, we find that the two plates are nearly the same by artificial light, whereas by daylight, the A plate is 6—7 times more sensitive to blue than to yellow, and B 11 times more sensitive to blue.

In the face of this glorious muddle, I may certainly ask whether I am not justified in calling attention to the subject, from what I hope is an independent standpoint.

It is obvious, I think, from the few facts just advanced, that, if the plate is to be exposed by daylight, sensitometric tests by artificial light are damned, because, if I may judge from my own practice, photographers are not in the habit of carrying about with them complete installations for illuminating all and every subject by gas, amyl, or benzine lights, or even standard candles.

E. J. WALL, F.R.P.S.

A TRIP to Fanatical Fez.—An interesting lantern lecture bearing this title was given at the New Gallery, Regent Street, on Monday evening last by Mr. J. H. Avery, the well-known photographer and traveller in Morocco. Mr. Avery, who has had the honour of instructing the Sultan of Morocco in photography and other up-to-date accomplishments, interpolated throughout his lecture many amusing and illustrative anecdotes relative to the life, customs, and manners of the inhabitants of this little-known region, and endeavoured to prove in an eloquent manner that the Sultan was a much misunderstood monarch.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES: HISTORICAL NOTE.

ON Friday week, October 14th last, at the New Gallery, after visitors had been received by the committee, the chairman of executive (Mr. C. H. Oakden), in the course of a short address, stated that the establishment of the Affiliation arose out of an explicit wish, on the part of some of the photographic societies in the country, to co-operate with one another for mutual benefit. It would be useful to shortly trace the history of the movement. Previous to 1889 some steps were made, but none of them with any great result. In 1889, Mr. H. M. Smith brought the suggestion under notice of the council of the Royal Photographic Society, who pointed a sub-committee to investigate the matter and report. About the same time Mr. L. M. Biden brought a scheme under notice of the photographic societies in the neighbourhood of London and a meeting was held at which the subject was discussed, but opinion was expressed that the movements should be undertaken by the council of the Royal Photographic Society. The report of the council's sub-council was further strengthened by the opinion expressed at the London meeting, and this ultimately resulted in the formation of the affiliation of photographic societies. The start was made in a small way, but the societies continually increased in numbers, until the present time. At first, business was conducted by the full body of delegates (the Royal Photographic Society pointing three delegates and each affiliated society two), but this was eventually found unworkable. The delegates then determined to transact the ordinary business of the affiliation through an executive council of ten, which they were empowered to do under the rules. This executive committee is elected annually by the delegates, so that each affiliated society can, if it wishes, take part in the election of their executive representatives. Since that time more progress has been made and the executive committee have endeavoured to provide the maximum benefits for the societies out of the funds at their disposal. They have provided lectures, accompanied by illustrations and slides, by competent writers. The executive committee gladly welcome suggestions as to the subjects for future lectures. Sets of lantern slides were also provided, and it was in order to meet this suggestion which was freely expressed, that lantern slides did not receive the recognition which it considered they should, that led the executive committee to establish the lantern-slide competitions which in recent years. Naturally a picture competition followed. The "red book" was also produced at considerable expense and trouble. At the present time in many places named in the list of permits the production of the "red book" was looked upon as a certificate of character of the holder. One warning upon the question of the use of the book appeared to be necessary. All permits granted to the owners of properties and custodians of buildings were granted as a matter of grace, the same as any ordinary permit. Members of affiliated societies should bear that in mind, and not attempt to claim that the permits entitled them to photograph as a matter of right and in contravention of the rules and regulations made for the comfort and convenience of visitors. The list of permits in the book is revised annually, and every endeavour is made to keep it up to date. The executive committee will continue their efforts to provide additional benefits in the future. In so doing they will bear in mind the necessities of such of the smaller and newer societies, which may not be favourably circumstanced, by having willing and capable workers in their ranks to assist them with advice and to guide the members in their efforts. The council of the Royal Photographic Society had always been willing to assist the affiliation whenever approached, and no reasonable request has been refused. The last request made to them resulted in this meeting, at which the attendance has exceeded all expectations, so much that it may safely be said that similar meetings will be held in the future.

A HAVERFORDWEST photographer did a good stroke of business over the unveiling of the county war memorial on Friday. At nine o'clock on Saturday morning he was out with some pretty and very effective picture postcards of the ceremony. As it was market-day, which half the people in the county visit the old town, his cards sold as quickly as they could be printed. And yet there are people who call Haverfordwest a slow town.

Exhibitions.

EDINBURGH AND MIDLOTHIAN INDUSTRIAL EXHIBITION.

PHOTOGRAPHIC SECTION.

In addition to the awards given last week, the prize-winners in the professional section of this exhibition are as follows:—

Portraiture: 1, Dan Dunlop, Motherwell; 2, H. S. Harrison, Edinburgh. Portraiture (Child): 1, Dan Dunlop, Motherwell. Landscape: 1, Dan Dunlop, Motherwell. Enlargements: 1, John R. Harper, Edinburgh. Carbon Work: 1, Dan Dunlop, Motherwell. Any other Subject: 1, Dan Dunlop, Motherwell. Enlargements, any Subject: 1, Dan Dunlop, Motherwell. Oil Painting (Original or Copy): 1 and 2, Miss M'Culloch, Kilmarnock; 3, Miss Howsley, Chesterfield. Water-colour Painting: 1, Miss M'Culloch. Chip Carving: 1, Herbert Metcalfe, Buzzard; 2 and 3, John Fraser, Edinburgh. Carving, A.O.D.: 1, J. T. Negus, Cambridge; 2, Frank G. Horsman; 3, Wm. Hughes. Poker Work: 1, 2, and 3, A. Davidson, 13, Teviotdale Place. Work Not Classed: 1, Albert Bonner, London. Poker Work, A.D.: 1 and 2, Miss N. D. Price, Irvine; 3, Miss C. Thompson, Leith. Work Not Classed: 1 and 3, Miss M'Culloch, Kilmarnock; 2, Miss E. Summers, Hull. Cabinet Work: 1, John Perrin, Halifax; 2, Joseph Ellison, Keighley; 3, F. E. Drury, Keighley. Carpentry, A.D.: 1, T. E. Drury, Keighley; 2, Edwin Hoyle, Keighley; 3, Benjamin Holmes, Keighley. Woodwork, A.O.D.: 1, T. E. Drury, Keighley; 2, Arthur Davy, Keighley; 3, F. E. Drury, Keighley. Nut Wood: 1, Benjamin Holmes, Keighley; 2, John Perrin, Halifax; 3, Benjamin Holmes, Keighley.

ROTHERHAM PHOTOGRAPHIC SOCIETY.

The fifteenth annual exhibition of this society was held in the Rotherham Drill Hall, on October 19, 20, 21, and 22, and proved exceedingly successful. The opening ceremony was undertaken by Lady Holland in the presence of a large company. Mr. E. Isle Hubbard (president) occupied the chair. The society's policy of not charging entry fees to exhibitors again met with ample recognition, and there was an extensive and interesting display of work. Altogether there were 224 frames in the open section, noteworthy classes being previously medalled work, architecture, still life, etc. The members made an improved show, there being altogether over 700 prints on the walls. The scheme of arrangement, including special electric light installation, met with general commendation. The Affiliation of Societies' (R.P.S.) prints were also on view. Each evening there was instrumental music, cinematograph and lantern slide exhibitions. The judges, Messrs. C. Barrow Keene, F.R.P.S., and T. A. Scotton, both of Derby, made the following awards:—Open Section—Class A: Champion class, any photograph previously medalled in open competition—Silver plaque; No. 4; Chas. F. Grindrod, Malvern; "Hauling Timber." Class B: Portraiture and figure studies—Bronze plaque; No. 35; Rachael L. Manners, Mansfield; "Despair." Bronze plaque; No. 54; Ernest H. Atkin, Nottingham; "Insight." Bronze plaque; No. 57; Wm. H. Foxall, Tunstall; "An Ancient Mariner." Class C: Landscape, seascape, and river scenery—Bronze plaque; No. 95; T. V. Simonson, Dore; "Autumn." Bronze plaque; No. 97; Charles F. Grindrod, Malvern; "Carting Kelp." Bronze plaque; No. 113; Dan Dunlop, Motherwell, N.B.; "In Birnam Wood." Class D: Architecture—Silver plaque; No. 147; Arthur de Silva, Sheffield; "In Torcella Cathedral." Bronze plaque; No. 167; Ernest H. Atkin, Nottingham; "The Sunlit Alley." Class E: Flowers, fruit, still-life, or other subject not included in the foregoing classes—Bronze plaque; No. 203; Dan Dunlop, Motherwell, N.B.; "Poppies." Bronze plaque; No. 204; Ernest H. Atkin, Nottingham (withheld); "Thistle-down." Bronze plaque; No. 209; Edward Seymour, Watford, E.; "Nettles." Bronze plaque; No. 207; F. Pinder, Burnley; "Animal Study." Class F: Lantern slides (sets of four)—Bronze plaque; F. G. Tryhorn, Lavender Hill, S.W. Bronze plaque; G. A. Booth, Preston. Bronze plaque; F. Parkinson, Spalding. Members' Section—Class G: Landscape, seascape, and river scenery—Bronze plaque; No. 215; R. H. Law; "Welcome Spring." Bronze plaque; No. 218; William Firth; "A Woodland Path." Class H: Architecture—Bronze plaque; No. 235; J. C. Cox; "Leicester's Hospital." Bronze

plaque; No. 242; H. C. Hemmingway; "The Nave, Chester." Class J: Miscellaneous subjects, not included in the foregoing classes—Bronze plaque; No. 246; J. W. Stamp; "Harvesting." Class K: Lantern slides (sets of four)—Bronze plaque; W. Firth. Class L: Best board of exhibits—Bronze plaque; J. C. Cox. The plaque has been specially designed for the society.

KETTERING.

THE third annual exhibition of the Kettering Photographic Society was opened at the Church Institute, Kettering, on Tuesday last. The entries totalled over 250 pictures, and with regard to quality the show proved to be a marked advance on previous years. The judge, Mr. W. R. Bland, of Duffield, Derby, appeared to have given great satisfaction as the outcome of his decisions. The exhibition was opened by Mrs. Wentworth Watson, of Rockingham Castle. The awards in the open section were:—Landscape and seascape, Mr. W. Clayden, Plymouth, first, for "A Gleam of Light"; E. J. Jarvis, Plymouth, obtained second. C. D. Taylor, Birmingham, was h.c. for "The Hillside"; J. W. Johnson c. for "Golden Cross Passage, Shrewsbury"; and E. J. Jarvis c. for "The Pride of the Morning." Others which should be noticed were from A. W. Walburn, West Hartlepool; S. G. W. Stevenson, Sevenoaks; H. M. Hames, Boston; A. M. Berry, Henley; W. Pinkney, Newcastle; S. C. Burgess, Ashby-de-la-Zouch; G. Franklin, Tonbridge; Miss Lacy, Hants; and W. Stainthorpe, Saltburn. There were eighteen specimens in the class for architecture, interior or exterior. Mr. S. G. Kimber, Southampton, was awarded first for "A Shaft of Light"; the second was given to Mr. J. W. Johnson, Kettering, for "Moreton Corbett Church." S. G. Kimber, Southampton, was h.c. (debarred) for "From Transept to Nave, Winchester"; Mr. A. W. Walburn h.c. for "An Old-time Street"; and Mr. F. T. Pinkney, Newcastle, c. for "An Open Door." Others were from various parts of the country, including three portraits from Miss Tyrwhitt-Drake, Hemel Hempstead. Portraiture, figure, flower, fruit, or animal studies had 25 entries. H. M. Hames, Boston, was first with "An Old Cobbler at Work." Mr. J. Smith, Hastings, was second with "A Veteran." J. Smith, Hastings, was also h.c. for "A Typical Fisherman"; W. Clayden, Plymouth, h.c. for "Home Life"; and H. Banston, Halifax, c. for "A Vegetable Shop." Lantern slides (sets of three): 1, T. G. Tryhorn, London; 2, F. Parkinson, Spalding; c., H. Wormleighton. Photographic Postcards (sets of three): 1, W. Pickering, Bishop Auckland; 2, W. F. T. Pinkney, Newcastle; h.c., H. C. Cross, Cotingham; c., J. T. Roberts, Gravesend.

FORTHCOMING EXHIBITIONS.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Barnbygate House, Newark.
November 2-23.—Plymouth. Hon. Sec. Photographic Section, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.
November 3.—Frome M.I. Photographic Society. Hon. Secretary, B. J. Mitchell, 3, Willow Vale, Frome.
November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.
November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.
November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, 52, Frederick Street, Sunderland.
November 17-18.—Braintree and Bocking Camera Club. Hon. Sec. W. H. Tilston, 81, High Street, Braintree, Essex.
November 17-19.—Darwen Photographic Association. Hon. Sec., J. G. Thomas.
November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.
November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.
November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.
November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarnock Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 12-14, 1905.—Boston Camera Club. Hon. Sec., H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Sec. John B. Parnham.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Essot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—The "Graphic." £50 in cash prizes. Manager, Photo Competition, the "Graphic," Tallis Street, Whitefriars, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Patent News.

The following applications for patents were made between October 10 and October 15, 1904:—

Developing Rocker.—No. 21,688. "Photographic developing rocker." Arthur Ernest Thwaites.

Panoramic Cameras.—No. 21,830. "Improvements in panoramic cameras." Wallace Fairweather.

Negative Frame.—No. 22,077. "A negative frame with triple plate-holder for colour photography." Jean Frachebourg.

Photographic Apparatus.—No. 22,134. "Improvements in photographic apparatus." Walter Frederick Giles.

Cameras.—No. 22,163. "Improvements relating to photographic cameras and the like." Henry Frank Purser.

Plates Cleaner.—No. 22,207. "A substance for cleaning and removing the scum from gelatine shading plates." George William Dick.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
29.....	Royal Photographic Society ..	<i>The Engadine and Lucerne.</i> Samuel J. Beckett, F.R.P.S.
31.....	Southampton Camera Club	<i>A New Carbon Paper.</i> Demonstrated by Mr. W. A. Max Mills.
31.....	South London Photo. Society..	<i>Trimming and Mounting.</i> Mr. Calder Marshall.
Nov.		
1.....	Nelson Photographic Society ..	Members' Lantern Slide Evening.
1.....	Glasgow Southern Ph. Assn....	<i>The History of Photography.</i> James M. Maclean.
1.....	Hackney Photo. Society	<i>Amateur Photographer Slides.</i>
1.....	Sheffield Photographic Society	<i>Field Days of a Sun Artist.</i> Percy Lund.
2.....	Edinburgh Photo. Society ..	<i>The Picturesque in Parks and Gardens.</i> Mr. James Craig.
2.....	North Middlesex Photo. Soc....	Lantern Slide and Print Competitions.
2.....	G.E.R. Mechanics' Institution	<i>Some Novelties in Cameras, etc.</i> Messrs. Beck. Mr. Slater, F.R.P.S.
2.....	Boro' Poly. Photo. Society ..	Members' Night.
2.....	Redhill and Dis. Camera Club..	Lantern Night. Members' Slides.
2.....	Cricklewood Photo. Society....	<i>Amateur Photographer Prize Slides.</i>
2.....	Windsor Camera Club	<i>Carbon Processes.</i> Demonstrated by Messrs. Illingworth & Co.
2.....	Everton Camera Club	<i>Devonshire.</i> Mr. E. Youds.
3.....	Southport Photo. Society.....	<i>Bromide Contact Printing.</i> Mr. J. Rigby.
3.....	Hull Photographic Society	<i>Lantern Slide Making.</i> Demonstrated by Mr. J. W. Atkinson.
3.....	London and Prov. Photo. Assn	Lantern Night for Mrs. Welford's and Members' Slides.
3.....	Liverpool Amateur Ph. Assn	Lecturette Evening (Architectural).
3.....	Watford Camera Club	<i>Amateur Photographer Prize Slides.</i>
3.....	Richmond Camera Club	Lantern Night.
3.....	Rongten Society	Ordinary General Meeting.
3.....	Ealing Photographic Society ..	Miscellaneous Lantern Slides.
4.....	Wakefield Photo. Society	Members.
4.....	Boro' Poly. Photo. Society	<i>Photography Prize Slides.</i>
		<i>Lantern Slide Making.</i> Mr. W. Page.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A COMMITTEE meeting was held, before the annual general meeting, on Friday, October 21st, at the Royal Photographic Society, 66, Russell Square. Present: Messrs. Alfred Ellis, F. A. Bridge, Martin Jacolett, Lang Sims, Wm. Grove, H. C. Spink (Brighton), A. Mackie, J. Edmonds (Hull), E. Scamell, P. Lankester (Tunbridge Wells), T. C. Turner (Hull); Mr. Alfred Ellis, president, in the chair.

After the items in the agenda were disposed of, which consisted of the reading of letters from members asking advice, etc., the financial arrangements for the annual general meeting, etc., the committee passed a very hearty vote of thanks to their retiring president, Mr. Alfred Ellis, for his indefatigable efforts to further the interests of the association and for the great encouragement he had given all the members of his committee in their work.

The fourth annual general meeting was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, October 21st, 1904. Mr. Alfred Ellis, President was in the chair, and there was a good attendance of members.

The annual report of the Committee was read:—

ANNUAL REPORT.

Since the last annual general meeting 57 new members have joined the association. During the year three members have died, six have formally resigned, and letters addressed to ten have been returned marked "gone away," "address not known." The number of members on the books at present is 604, but 69 of these have not paid last year's subscription, after four applications, and in default of payment at the time of publishing the next Handbook these names will not be included in the list of members. The accounts show that there was a balance of £88 0s. 6d. in the hands of the hon. treasurer on June 30th the termination of the financial year. The Fine Art and General Insurance Company have issued 64 policies to members, the annual premiums amounting to £117 7s. 1d. Three members' meetings have been held, and the proceedings have been reported in the BRITISH JOURNAL OF PHOTOGRAPHY. The General Committee have held 11 meetings and the average attendance has been 12. Special sub-committees have held six meetings. The local branches at Edinburgh and Liverpool and Hull continue active. The annual dinner was duly held, and was a very pleasant gathering. There was, however, considerable falling off in the attendance, and as it is evident that

there is no general desire for a gathering of the kind, and as there are many expenses connected with it which are not covered by the price of the ticket, and which cannot be charged to the association's funds, and have therefore to be met by private contributions, the committee have decided to recommend that a dinner shall not form part of the official programme. An exhibition of work by the members was held during the months of June and July, including the convention week, in the Corporation Art Gallery at Derby. Although many members had from time to time expressed a wish for the opportunity of such an exhibition it was only with great difficulty that a sufficient number of entries could be obtained to fill the galleries, although no charge was made. The experiment will probably not be repeated. The thanks of the association are due to the Mayor and Corporation of Derby for placing the Art Gallery at our disposal, and to Mr. W. Crowther, the Curator, for his valuable services in connection with the exhibition.

Applications for advice continue to be numerous, and, although the subjects range over a wide field, a large proportion are with regard to copyright matters. The committee are always glad to assist members in their business difficulties, but they feel bound to say, with regard to copyright difficulties, that in nearly every case brought to their notice, the difficulty would not have arisen if the applicant had previously studied the information about copyright given in the Handbook and had adopted the methods there advised. Continual complaints are received of failure to obtain payment from Press agencies. If before entering into business relations with any agency a reference were made to the hon. secretary as to its commercial standing these troubles would often be avoided. Advice given by the committee has undoubtedly often prevented members from commencing legal proceedings on a case which it is hardly possible could succeed, and the mediation of the hon. secretary in several cases of disputed account, or in some cases of the hon. solicitor, has been successful in promoting a settlement. In the course of the year a dispute as to the value of photographs supplied giving rise to an action in the Reading County Court, was referred to the committee for arbitration by His Honor the Judge, and in due course the committee made an award. The committee have spent much time in considering a scheme for granting certificates of proficiency to operators, assistants, etc. This has now been published, but before issuing the prospectus as an official document it has been thought desirable to invite general opinion as to the provisions and regulations with a view to ensuring that the system finally adopted shall be equally acceptable to employers and employed.

The thanks of the association are due to the Royal Photographic Society for allowing the meetings to take place at their house, and to the Editor of the BRITISH JOURNAL OF PHOTOGRAPHY for publishing notices, reports, and other information relating to the association. The committee also wish to express their indebtedness to the hon. solicitor, Mr. Percy E. Marshall, for the valuable assistance he has rendered them.

WILLIAM GROVE,
Hon. Secretary.

Mr. Jacolette said he was sorry it had been deemed advisable to exclude the annual dinner as part of their official programme, but as so little support had been given to it by the members, and as any loss could not be made good from the Association's funds, he thought the Committee had done wisely in abandoning it. Personally, he more regretted this being done as on these occasions he had met many very dear friends of the photographic profession.

Mr. Birtles, of Warrington, suggested that the dinner should be held at Manchester or Liverpool, as it could not be expected that members would journey all the way to London to attend a dinner.

The President said he was afraid that if the London men would not attend the dinner when held in London, they were not likely to go all the way to Liverpool or Manchester to attend. He saw no reason why a dinner should not be held, but it was thought advisable not to include a dinner in their official programme.

On the proposal of Mr. J. Done, seconded by Mr. C. H. Skillman, the report was adopted.

Two reports from the local branches, Edinburgh and Liverpool, were then read.

Mr. T. C. Turner said that only two meetings of the Hull branch had been held, at which the business transacted had been duly reported in the BRITISH JOURNAL OF PHOTOGRAPHY. Among the sub-

jects discussed was the question of assistants' certificates, the proposed Benevolent Fund, and the abuse of proofs. He found that large quantities of untuned proofs were systematically brought from time to time to dealers and others to be toned. It was hardly possible that this practice should be allowed to go on to any great extent, and the matter required very serious attention. A suggestion had been made that all proofs should be stamped across the front with the name of the photographer issuing them. He thought it well to mention that at their first meeting at Hull they well discussed the Oxo business, which has now been settled, and another big meat extract firm finding there was such strong feeling on the part of photographers had abandoned their intention of initiating a similar enlargement scheme.

The Hon. Treasurer read the balance-sheet. The financial statement was thought to be very satisfactory, and it was proposed and carried that the balance-sheet as read be adopted.

The names of those gentlemen nominated as officers for the ensuing year were read. As the nominations exactly filled the vacancies no ballot was necessary, and the President formally declared that the gentlemen nominated were elected. Officers elected:—President T. C. Turner (Hull); vice-presidents, Wm. Crooke (Edinburgh), Martin Jacolette (London), A. F. Mowll (Liverpool); committee (London members), Arthur C. Banfield, F. A. Bridge, Ernest C. J. Elliott, S. Herbert Fry, Wm. Grove, H. Edmonds Hull, Alex. Mackie, H. S. Mendelssohn, Daniel Prodger, Edgar Scamell, Lang Sims, R. Fellowes Willson; country members, Wm. Barry (Hull), H. A. Chapman (Swansea), Wm. Gill (Colchester), Percy Lankester (Tunbridge Wells), Frank P. Moffat (Edinburgh), G. W. Morgan (Aberdeen), Ralph W. Robinson (Redhill), Henry C. Spink (Brighton), G. Watmough Webster (Chester), Alfred Werner (Dublin). Messrs. M. B. Barraud and Frank Turner were elected as auditors.

Certain alterations in the rules, recommended by the Committee, were then read and adopted. This completed the formal business of the annual general meeting.

The President said a copy of the tentative scheme for granting certificates to operators' assistants, etc., was in the hands of all present, but as they would not have had time to grasp the details he would not ask for a formal discussion and would not put any resolution to the meeting. The Committee, however, would be glad to hear any comments. The intention of the Committee was to elicit the opinions of as many professional photographers as possible on the scheme as it stood, and before finally issuing their prospectus to consider carefully the suggestions that may be made to them. To this end the scheme had been published in the BRITISH JOURNAL OF PHOTOGRAPHY, and an invitation had been given by the Hon. Secretary to all interested to state their views.

After several questions upon points of detail had been asked and replied to

Mr. T. C. Turner said he was of opinion that it was hardly the time or place to go into details of the scheme. Photographers could hardly realise what it meant to them if they would only back it up. He suggested that all the details of the scheme be left to the Committee to work out, after receiving suggestions. He was of opinion that the depression in photography was due to unskilful work. Master photographers should be highly educated in their work, and their natural successors were those who had been assistants. The reason so many photographers went down to-day was that the clever men of yesterday had no clever men to follow them, that the assistants could not follow them.

Mr. Jacolette said, on behalf of the Committee who had spent a very great deal of time and labour in thrashing out this question, he would ask the members outside the Committee to thoroughly interest themselves in the matter, and to add their experience to that of the Committee. If they would only do as their President suggested, i.e., take the draft of the scheme away with them and give their time and consideration to it, he was sure the suggestions sent in would receive every consideration. He was convinced of the ultimate good which would accrue to photographers as the result of such a scheme. If the scheme was not supported, and they afterwards got bad and inexperienced assistants, they would fully deserve it.

Mr. Prodger asked if the views of assistants could be given.

The President replied they were anxious to obtain the views of assistants, and announced that the Committee would meet on November 11 to consider the suggestions that had been sent in. With regard

to the final item on the agenda, the consideration of Mr. Snowden Ward's suggestion of the formation of a Benevolent Fund, Mr. Snowden Ward had been invited to be present, and he would ask him to place his views before the meeting.

Mr. Snowden Ward said that before giving his reasons for the suggestion that a new Benevolent Fund should be instituted, he should like to give an emphatic denial to the suggestion which he understood had been made in some quarters that the funds of the late P.B.A. had not been entirely devoted to the purpose for which they had been subscribed. During the many years he had been connected with the administration of the Association, with the exception of the comparatively small amount which had been spent in necessary office expenses, postage, printing, etc., he was certain the whole of the funds had been properly devoted. At the final dissolution of the Association the balance of the funds was devoted to the payment of a weekly allowance of 3s. to a provincial photographer who had been of some standing but was then incapable of work, and this sum, together with 3s. and a loaf of bread which the parish allowed him, was all he had to live on. His reason for calling the attention of the Professional Photographers' Association to this matter was simply this. He was practically the last secretary of the late Benevolent Society, and people in distress and photographers who wanted to help people in distress were frequently writing to him. The reply he was obliged to make was that it was not his business to run a Benevolent Association. In the case of the photographer he had referred to, when the funds of the Benevolent were exhausted he made an appeal, and received from a few people enough money to keep that man going for five years or more. But what he wanted to do was to be in a position to give a definite reply to people who are constantly saying that it is his duty to be responsible for the Benevolent Committee, and he hoped that after this meeting he would be able to reply in a manner these people expect. He gave examples of the manner in which assistance had been rendered to photographers who once had been in good ways of business, and expressed the hope that the P.P.A. might see its way to take up the whole question. He suggested a possible committee of eighteen, six from the P.P.A., six from the Royal Photographic Society, and six of the late committee of the Benevolent Society, of which he thought a few remained, notably, one in the person of Mr. Mackie, who had given such valuable assistance formerly. As regards support, he had not the slightest doubt that there would be plenty forthcoming, as he had since the publication of his intended proposal received many interesting letters and promises, one of which being from one of the largest manufacturing concerns in the country. In conclusion, he felt sure that with sympathetic administration a small fund could be made to go a long way in alleviating cases of distress.

Mr. Jacolette said he was greatly in sympathy with the proposal, but he would remind the members that their committee had already had some experience in these matters. During the presidency of Mr. T. Bedding they had suggested a Benevolent Fund as part of the Association, and they found so little support then that they did not feel justified in spending time and energy perhaps better devoted to the primary interests of the Association. He hoped that as far as this Association was concerned, whatever alms were administered would be administered to members of the Association simply. It was not their object to go outside the Association, and personally he was of opinion that efforts should be within their own arena.

It was intimated that four letters had been received by the Hon. Secretary in reference to the scheme promising support.

Mr. Ellis asked Mr. S. Ward how many promises he had received from provincial photographers, and received the reply, "Not more than three or four."

Mr. A. Mackie said one point to the advantage of the new scheme was that in the time of the old Benevolent Association it was said to be impossible for photographers to combine at all. That it was not impossible now was exemplified by the Association, and possibly a much larger number of them might take up the Benevolent scheme. In the old Benevolent Association they never had more than forty subscribers who were professional photographers, although the subscription was only 2s. 6d. per annum. The fact that there were letters from professional photographers anxious to assist showed that there is a greater chance now of success.

Mr. Groves brought under notice the fact that he had received a

cheque for a guinea towards the fund, as notified in a letter to the Editor of the BRITISH JOURNAL OF PHOTOGRAPHY.

Mr. Lang Sims said he was deeply interested in the proposed scheme, but he did not agree with Mr. Jacolette. If the scheme was taken up by the P.P.A. they must take in the whole of the profession. If they got a nucleus of £200, he did not think there would be any difficulty in forming a big Benevolent Fund. He was anxious that the scheme should go through. It was P.P.A. work and would be safe in the hands of the Committee.

Mr. Done said he would like to know if it was intended to confine this Benevolent Fund amongst photographers, or whether it would be thrown open to camera makers, plate makers, etc.?

Mr. Ellis said they were waiting to see what support they could get. The Committee would then see whether it was possible to go on with the matter. They wanted to hear all sides, and all suggestions so that the new Committee could go further into the matter and report upon it. They could not ask for money until they had a proper scheme. Getting at the easy part of it first, no doubt they could get sufficient money for what is required. But there is a very great doubt as to whether they had the machinery to apply the money properly. At the present moment they had not. It was necessary before giving money to find out whether the case was a genuine one. Inquiries would have to be made. It would be a very wrong thing to receive money until they were ready to apply it. Personally he felt very strongly about it. As long as he had known anything of photography when money was wanted, it was the custom to go round and rely upon the trade for the principal portion of the money subscribed. This should not be, and he strongly protested against any application being made to traders and trade companies to assist. Charity should come from themselves.

Mr. Gill said it seemed to him that in connection with this subject they were dealing with a matter of charity, and not a business matter. He thought the less money spent upon machinery and distribution the better. Ordinary Charity Organisation Society methods did not appeal to him where charity was in question. If they selected the right men they could leave the question as to whether the need was justified to them.

After further discussion the Chairman said it was not proposed to take any resolution which would pledge the Association to any course that evening.

Finally, it was proposed by Mr. Rigden, seconded by Mr. Cherry and carried, that Mr. Snowden Ward's proposal be favourably considered by the P.P.A.

The meeting terminated with the proposal by Mr. Lang Sims of a very hearty vote of thanks to their retiring President, Mr. Alfred Ellis, for the valuable services he had rendered the Association during his year of office.

This was enthusiastically carried.

GLASGOW AND WEST OF SCOTLAND.

THE first meeting of the Glasgow and West of Scotland Amateur Photographic Association was held on Monday evening. This being the annual general meeting, the annual report of the secretary and the treasurer's statement were submitted, and it is gratifying to note that the funds show a balance of £60 to the good on the year's working. After the election of office-bearers, the new president, Mr. Jas. W. Reoch, gave his presidential address. The subject chosen was a retrospect of experiences during the past twelve years, and a brief history of photography from its commencement. Photography holds the palm for being the most varied and many-sided of the hobbies that one may take up, and it leads one into paths of pleasantness and wonder. Some of the works evolved in recent years are the X rays, cinematograph, and three-colour work. After alluding to the work done by Niepce, Daguerre, Fox Talbot, and others, in the early days, the lecturer stated that Fox Talbot and Herschel were in reality the founders of photography. Coming down to the present, photography now was an immense subject to grasp thoroughly. Many were the roads that radiated from it—chemistry, optics, physics, astronomy, and these and many other things were indebted to it. Time to most of us prevents us from following it in many of these roads, and the photographer therefore must specialise. The powers of observation were quickened and enlarged, so that with an artist's standard of feeling the photographer goes to nature and selects and composes a picture and passes

by the rest. The scientist will produce the best negative, but the combination of artist and scientist is the best. Mr. Reoch concluded his remarks by alluding to the glorious prospect unfolded before the student of photography, and the pleasure to be derived from its pursuit, and finally the advantages offered in such a society in the help it affords the amateur in his work.

CROYDON CAMERA CLUB.

OCTOBER 19th.—Principally for the benefits of beginners, Mr. A. E. Isaac gave a lucid and interesting exposition on lantern slide making, dealing both with the cold tones resulting from normal exposure and developments, and the warmer tints obtainable by increasing the exposure and restraining the developer in the well known manner. In the short discussion which followed, a question was raised as to the why and wherefore a lantern slide showed such slight traces of halation, having regard to the tenuity and transparency of the film. Mr. Isaac said that halation seldom, if ever, appeared in contact slides, but when they were obtained by reduction this defect occasionally showed, especially if a strong illuminant were employed. The president, Mr. S. H. Wratten, also pointed out in this connection that a lantern emulsion was but slightly sensitive to the red end of the spectrum, and the film itself, being of a ruby colour, rays reflected from the back of the plate were in a large measure robbed of their actinic value.

DEVONPORT CAMERA CLUB.

OCTOBER 19.—The autumn session of Devonport Camera Club was opened. The President (Mr. W. H. Mayne), in an address, said photography had proved itself artistically capable of effecting results which not so very long ago the prosaic party would have denied the possibility of its ever achieving. Capabilities or tendencies unsuspected in the past must lead one to anticipate development in the future. What to-day was declared a presumption to attempt would be passed by to-morrow as too familiar to be even remarked upon. The photographer-artist was becoming more and more the master in the literal sense. He could command, even if within a small area, for he was not entirely under the domination of his camera and chemicals. Never was photography so popular as at present, and never before was the hand camera so much in vogue. There was no other hobby which brought so many subsidiary advantages as photography. It opened up for the serious student many branches of study, perhaps, either partly or wholly neglected. There followed a natural desire to imitate; hence the student was driven out in the haunts of Nature to get the materials for his picture. He learned more and more of her beauty, studied with more loving attention her changing moods, learned to love her more subtle aspects, and to work on an altogether higher platform than formerly. The more they knew the more they desired, and so the study of pictorial composition became a passion, ever increasing with added experience. The past year of the club had been a record one. The most important event had been the first open exhibition ever held by the club, and proved the finest and best held in the West of England. He should like to see a continuation of the exhibition, and expressed the hope that it would be supported by every member, and not leave it to a percentage to make the event a success. He pleaded for a larger membership, believing that there were a large number of amateur photographers still outside who could well be brought inside. The lecture by Mr. F. J. Mortimer on "Marine Photography," was read, the pictures shown being exceptionally fine.

PLYMOUTH PHOTOGRAPHIC SOCIETY.

Mr. J. TROUREN TREND, the hon. treasurer, reported at Plymouth Photographic Society's annual meeting last Wednesday evening that on the ordinary work of the year there was a loss of 2s. only. Unfortunately, however, the exhibition organised in the spring was so little appreciated that it involved the society in a loss of £12. Against that sum, however, there were assets of £10 13s. The President (Mr. F. Johnson), moving the adoption of the report, said the position was not discouraging. The society had discharged a public duty in affording an opportunity for enjoying some of the best photographic work of the day. That it was not appreciated was no fault of the society, although it had to bear the loss. Football seemed to be the only thing in the town just now. Mr. J. T. Johnson was elected president. Messrs. H. S. Hill and F. Blanchard were elected vice-presidents. Mr. J. T. Trend was re-elected hon. treasurer, and Mr. A. W. Hicks hon. secretary. A special vote of

thanks was very heartily accorded Mr. W. Grist for the great services he had rendered the society during the four years he held the secretaryship. The ballot for the committee resulted in the election of Messrs. Grist, F. Johnson, Clayden, E. G. Turney, Dymond, Bowtell, Coleman, and Wibling. Messrs. F. Johnson and W. Clayden were elected as delegates to the Royal Photographic Society.

SHROPSHIRE CAMERA CLUB.

THE annual meeting was held at Castle Chambers, Shrewsbury, on Wednesday last. The President (Mr. H. W. Hughes) gave a brief review of the work of the past year. A circular had recently been sent out urging the claims of the photographic survey of Shropshire, and the President appealed to the club to take part in this useful and interesting work. The hon. treasurer presented his accounts, which, notwithstanding some exceptional expenditure, showed the largest balance-sheet he had yet had. The president, vice-presidents, treasurer, and secretary were re-elected, and two vacant places on the Council were filled by the election of Messrs. J. Gouldbourn and W. H. Witherby.

Mr. W. E. Harding gave an interesting account of travel in Spain, which was well illustrated by a large number of lantern slides. One of the chief features of the evening was a small but very interesting exhibition of pictures lent by two well-known photographers, Mr. J. Cruwys Richards and Mrs. Dumas. Mr. Richards sent a number of portraits and figure-studies in gum bichromate, and Mrs. Dumas lent some very beautiful pictures of woodland scenes.

EALING PHOTOGRAPHIC SOCIETY.

OCTOBER 20.—Annual general meeting. The council were able to report that the society may be considered as in a flourishing condition. There are seventy-one members on the list, and the accounts show a balance of £12 12s. 4d. in hand. The president, Mr. W. T. White, who has held office for four years, tendered his resignation, not because he took less interest in the society than formerly, but because he thought a change would be beneficial. On his nomination, the hon. secretary, Mr. J. Watson, was unanimously elected to succeed him. The remaining officers for the ensuing year are:—Council, Messrs. Fryer, Pelling, F. C. White, Stewart, Clifton, and Portway; hon. curator and lanternist, Mr. A. Richardson; hon. treasurer, Mr. A. F. Taylor; hon. secretary, Mr. S. Taylor, 38, Hamilton Road, Ealing, W.

KINGSTON PHOTOGRAPHIC SOCIETY.

THE Kingston and District Photographic Society opened its winter session at headquarters, the Sun Hotel, on Monday evening last. It is customary to hold a series of twenty lectures, demonstrations, etc., ten before and ten after Christmas, all the meetings taking place on Monday evenings. The first of the present series proved very successful, the subject being "Animal Studies," illustrated by slides lent by Mr. Lewis Medland, who is well known in connection with this branch of photography. Mr. Medland was unable to be present, and the slides were entrusted to Mr. W. R. Stretton (a vice-president), who announced the names of the animals as they appeared on the screen. In the course of a subsequent discussion, Mr. East explained that at illustrated lectures the heat of the room condensed on the slides, and the reason the views were so clear that evening was because the slides were warmed by means of hot water. This was the suggestion of Mr. H. M. C. Sprunt, their hon. lanternist, and he believed that Kingston was the only place where this effective method of overcoming the difficulty was in use. After Christmas the headquarters of the society will be at the hall of the new Museum. Mr. East, to whom a large measure of the success of the society is due, is shortly leaving for South Africa, and in his absence all the secretarial work will be carried out by Mr. A. W. Grant, of Woodleigh, Cranes Park Avenue, Surbiton.

In the photographic competition instituted by "Parke's Drug Stores, Limited," the following awards were made:—First prize, J. F. Johnson (Harlesden); 2nd, Mrs. M. E. Turner (Stroud Green); 3rd, E. A. Perfit Harvey (Whitehall Park, N.) Commended, T. McCallum, T. C. Edwards, W. J. Jones, and A. B. George.

News and Notes.

THE Stanley Cyclists' Photographic Society has been formed at 106, Tollington Park, London, N., and is, we are informed, progressing with a great amount of success.

THE Cripplegate Photographic Society announce that the annual exhibition will be held on the following dates, viz., March 20 to March 23, 1905, inclusive.

THE annual general meeting of the British Optical Association will be held on Wednesday, November 16, at 2.30 p.m., in the Lecture Hall of the Mount Vernon Hospital, Fitzroy Square, W.

RICHMOND Camera Club.—Mr. J. A. Abbott, of St. Leonard's Place, East Sheen, is the new hon. sec. of this club, vice Mr. Richardson, who has resigned.

THE R.P.S. Exhibition.—We would remind our readers that tomorrow (Saturday) is the last day of the R.P.S. Exhibition at the New Gallery, Regent Street. Those who have not already visited the show should do so before it is too late.

SHEFFIELD Photographic Society.—Entries for the forthcoming exhibition of this society close on Saturday, November 5. The opening ceremony will be performed by the Lord Mayor-Elect of Sheffield. The Hon. Sec.'s address is 62, Vale Road, Sheffield.

BOLTON Amateur Photographic Society.—The winter syllabus of this society is now in course of preparation, and the secretary, Mr. A. Robinson, of 2, Fold Street, Bolton, will be glad to hear from any gentleman who are willing to deliver lectures or give demonstrations.

NEWPORT Photographic Exhibition.—The second exhibition of the Isle of Wight Photographic Society was held in the Medina Hall, Newport, on Wednesday and Thursday last. The opening ceremony was performed by Mrs. Godfrey Baring, and Professor J. Milne, F.R.S., F.G.S., presided.

BIRKENHEAD Photographic Association.—The opening meeting of the winter session was held in the Y.M.C.A. Rooms on Friday last. The president, Mr. R. J. Russell, presided. A lecture was delivered by Mr. E. Rimbault Dibdin, curator at the Walker Art Gallery, Liverpool, on "Sunny Seas and Sunlit Cities."

NOTICE of Removal.—Mrs. Alston announces that, owing to the increasing number of her pupils, she has been obliged to remove her studio from 175, New Bond Street to larger and more commodious premises on the first floor at 52, New Bond Street. At this address free demonstrations of crystoleum painting are being given daily from 11 a.m. to 12 noon.

THE annual general meeting of the Photographic Club will be held at the new headquarters, Huggett's Red Cross Hotel, 19, Paternoster Square, E.C., on Wednesday evening, November 2, 1904, to receive the balance sheet and report of the committee, to elect the officers and committee for the ensuing year, and to consider certain alterations in the rules, of which notice has been duly given.

BOWES Park and District Photographic Society.—On Monday last, at Unity Hall, a reception of members and friends of this society was held by the president and vice-president. Prints from photographs taken by members during their annual holidays were entered for competition, a good display being made. The following was the result of the voting:—Mr. A. Bird, 1; Mr. A. J. Craston, 2; Mr. Oliver, 3.

ABERDEEN Photographic Association.—This society held the first meeting of the present session in their rooms, 54, St. Nicholas Street, on Friday night last, the subject under discussion being the new Nernst burner, which was explained in an interesting manner by Mr. W. F. Borthwick, lanternist to the society. Discussion following, it was agreed to purchase one on behalf of the society, to be used both for lantern and enlarging demonstrations.

THE annual meeting of the Dundee and East of Scotland Photographic Association took place on Friday last. The following office-bearers were elected:—Mr. G. D. Macdougald, president; Mr. George Worrall and Dr. Cowan, vice-presidents. It was intimated that the

Council had arranged for a series of demonstrations, forming a complete course of instruction in photography for beginners, during the ensuing session.

SOUTHAMPTON Camera Club.—Mr. O. G. Pike, the well-known bird photographer, gave an illustrated lecture, entitled "In Birdland with a Camera," at this club on Monday last. The lecturer handled his subject in an instructive manner, and he took his audience into the haunts and homes of the rarest British birds, giving minute details of their habits and recounting many interesting episodes of the dangers encountered whilst obtaining the negatives for some of the unique lantern slides with which the lecture was illustrated.

MESSRS. CHAS. ZIMMERMANN AND Co., of 9 and 10, St. Mary's Hill, write:—"As many amateurs are at a loss to know what experience is entailed and what is necessary to thoroughly take up the new pigment paper printing process, we are issuing outfits as per circular enclosed." The outfit in question appears to include everything necessary for turning out finished prints in this process, and is very inexpensive. A postcard to above address will bring full particulars.

KING'S Souvenir of Bootle.—His Majesty the King has been pleased to accept an album containing photographs in connection with the recent opening of the Stanley Garden, Bootle, by the Earl of Derby. The principal view is that portraying the statue of the King, which forms the central figure in the gardens. The Mayor of Bootle has the honour on Tuesday last of presenting the souvenir to Lord Knollys, who received the gift on behalf of his Majesty.

THE Prize Distribution of 500 Cyko Cameras.—Messrs. John Griffin and Sons, Ltd., write:—"We find that the time allowed for purchasers of our Cyko Cameras under the scheme detailed in our published circular was insufficient to permit of them sending in pictures in competition. We have therefore decided to extend the last day of sending in entries until a date early in the spring of next year. This date will be determined as soon as a reasonable number of purchasers of these cameras have sent in pictures for competition."

At the Brentford Photographic Society on Tuesday last Mr. Turner, F.R.Hist.Soc., gave an address on "Record Work," and outlined a scheme for the new section just started. The society will be glad to hear from any one interested. The next meeting of the society will be on November 1. We hear the society is now in position to accept any gifts of books bearing on photography, etc., and the hon. sec., Mr. Hilton Grundy, North Grove House, Brentford, will be only too pleased to acknowledge any such gifts and put carriage on same if required.

SHEFFIELD Photographic Society.—A meeting of this society was held on Tuesday evening last at the Builders' Exchange, Cross Burgess Street. The society having arranged a course of elementary demonstrations for the benefit of the less advanced members, the first was given at this meeting by Mr. Thomas G. Hibbert on the making of lantern slides. Several slides were exposed and developed, and the result of over, under, and correct exposure shown. Instructions as to masking and binding were also given. A series of slides by Mr. Hibbert were afterwards exhibited on the lantern screen.

LIVERPOOL Amateur Photographic Association.—The weekly meeting of the members was held on Thursday last at the room in Eberle Street, Mr. F. A. Schierwater presiding. The lecturer for the evening was Mr. F. Anyon, who gave one of his practical demonstrations, his subject being the optical lantern. He illustrated and described the various principles governing the optical system, the various luminants, etc. The latter included acetylene gas by the latest approved methods, the new spirit lamp, the electric arc lamp, and the injector jet. The demonstration proved most instructive.

READING and District Photographic Society.—The annual meeting of this Society was held in the Abbey Gateway on Friday evening last. The Hon. Secretary presented a satisfactory report on the past year's working. Financially, the Society is in a good position. The Hon. Treasurer holding a balance of £4 8s. 9d.. Officers for the year were elected as follows:—President, Mr. Alfred Palmer, J.P.; vice-presidents, Mr. C. E. Keyser, J.P., and Mr. G. Gilligan, J.P.; honorary treasurer, Mr. G. W. Webb, J.P.; joint honorary secretaries, Messrs. C. A. Reading and George Green; committee, Captain J. E.

Henderson, Messrs. A. Burton, E. Cardwell, C. A. Elliott, D. Haslam, Jun., H. A. King, A. Malpass, and E. W. Tabor.

"ONE-WOMAN" Show at Russell Square.—The admirable collection of photographs by Mrs. G. A. Barton now on view at the Royal Photographic Society's Rooms, 66, Russell Square, W.C., will remain on exhibition until Wednesday, November 30. The pictures are all very fine examples of this well-known worker's peculiar and successful style, and are well worth considerable attention and study. The exhibition is open daily from 11 a.m. to 7 p.m., and permission to view to non-members of the Society will be gladly granted by the Secretary, Mr. A. W. W. Bartlett, at the above address. Sixty-seven pictures are hung, and we hope to notice some of them more fully on a future occasion.

SOUTHERN Photographic Society.—Mr. C. J. King, of St. Mary's, Scilly, delivered a lecture on "The Sea Birds of Scilly" at the Technical School on the 12th inst. In taking the photographs of puffins, shearwaters, petrels, terns, etc., much ingenuity has to be exercised in order not to alarm them. Mr. King said that on one occasion he spent five or six hours under a huge focussing cloth waiting for the moment when he could snap a crowd of puffins to the best advantage. At another time over a ton of stones and rocks were removed bodily in order to photograph the nest of a stormy petrel. This makes it clear why the eggs of this bird are so comparatively rare. The lecture was brought to a conclusion with some good photographs of breaking waves for which the Cornish coast is so well known.

NEWPORT Camera Club.—Mr. J. B. MacLachlan, of Blairgowrie, was the lecturer for the opening night of the session, and the Club Rooms held a keenly interested audience last Wednesday night, when he spoke from the text "Union is Strength." Mr. MacLachlan treated of the importance of combination in photographic work from various points of view. Specially he commended the value of club comradeship to the amateur, and, passing to speak of the larger unions, he detailed the aim and object of the Scottish Photographic Federation, with which he has been connected as secretary since the formation. The many and varied services this national union is able to afford were pointed out, and in interesting fashion the lecturer described the work accomplished by the Federation, with special reference to the salon at Perth, one of the notable successes of this year's efforts.

AMATEUR Photographers Open a New Studio at West Hartlepool.—The formal opening of a new studio formed the occasion of a very interesting and instructive gathering in connection with the West Hartlepool Amateur Photographic Society last Wednesday. The studio, which is situated in the Victoria Buildings, Tower Street, is in a most central position of the town, and should be the means of considerably adding to the strength and utility of the society. A very able and practical address on photographic printing processes was given by Mr. A. W. Walburn, who dealt principally with platinotype, carbon, and bromide, and showed the need for choosing the printing process to suit the particular subject and class of negative, besides giving a range of tones to be obtained on platinotype and bromide papers, and producing, in illustration, prints in black and white, sepia, blue, brown, and intermediate tones. The programme for the winter session is a very comprehensive one.

The Optical Society.—This society opened its winter session on Thursday night with a *conversazione* at its headquarters, 20, Hanover Square, W. Between sixty and seventy members were present, including Dr. R. T. Glazebrook, F.R.S., the president, Dr. C. V. Drysdale, Mr. C. Hyatt-Woolf, and Mr. W. A. Dixey, vice-presidents, and Mr. J. Aitchison, hon. treasurer. An exhibition of optical and other scientific instruments and apparatus had been arranged under the direction of Mr. W. Salt, the hon. secretary, and some interesting demonstrations were given during the evening. Mr. F. Harrison Glew showed some of the wonders of radium, and the working of various scientific instruments was explained. The exhibitors included Messrs. Adam Hilger (Ltd.), who showed a new spectroscope, Messrs. Sanger-Shepherd and Co., who showed a new camera for colour photography and other specialties, Messrs. Romaneet and Gilbert, who had a good selection of lanterns and arc lamps, Mr. R. W. Paul, and Mr. Aitchison.

"It may interest the amateur at home," observes a writer in one of the Glasgow papers, "to know the method recommended by an amateur in the South Sea Islands for varnishing a negative. He advises that a box, such as plates are sold in out there, is to be filled to a sufficient depth with varnish. After exposing the negative to the sun until warm, it is dipped face down in the varnish until it is covered up to, but not overflowing on, the back." A pneumatic plate holder was used to hold the plates and prevent the fingers getting covered with varnish, and meanwhile watching that there were no air-bubbles on the film side. Lift from the varnish by a tilting movement, which will allow it to drain off evenly, and place in an almost upright position in the sun to harden. The sun is never so intense in our northern clime as to be able to be annexed in this way by the amateur as an aid to varnishing, but the difference in the method in the South Sea Islands is interesting, if not possible here.

ROYAL Geographical Society.—The new session of the Royal Geographical Society opens on November 7, when Captain Robert F. Scott will deal with the leading features of the national Antarctic expedition of which he was commander. Captain Scott's lecture will be profusely illustrated with lantern slides; he has 2,000 photographs and hundreds of coloured sketches to select from. This meeting will be held in the Queen's Hall, and we understand that the demand for tickets by the Fellows for themselves and their friends far exceeds the accommodation provided in the hall. The Antarctic expedition will form a prominent feature in the proceedings of the session. At subsequent meetings Lieutenant Royds will deal with the meteorology of the expedition, Mr. Ferrar with the geology, Dr. Wilson with the zoology, and Mr. Bernacchi with the terrestrial magnetism. Moreover, Captain Scott has consented to tell the story of some of the leading incidents of the expedition to young people about Christmas, when again there will be an abundance of lantern illustrations.

SPORTING Photographs.—Everybody who has seen the fine volume just published by Mr. John Lane, "Fifty Leaders of British Sport," says one of the daily papers, "has been remarking on the wonderful portraits that illuminate the book, and surprise has been expressed that so many famous sportsmen should have been 'caught' by the camera while enjoying their favourite recreation. How was it, for instance, someone has asked, that Messrs. Elliott and Fry managed to catch the Marquis of Granby when he was playing a fish, with the water well up to his knees?" Mr. Ernest Elliott has now explained that most of the photographs were, as a matter of fact, taken in his studio in Baker Street. The stream in which Mr. Courtenay Tracy is otter-hunting, the wicket at which "Ranji" is standing in his well-known attitude, the jungle wherein Gen. Sir Montagu Gerard is looking for tigers—all these and many others, were "built" in Baker Street. Looking through the originals it was a matter of considerable difficulty to select those which were taken in the open air from those which were not. The deception is really astounding, and Mr. Elliott not unnaturally is pleased with the result of his two years' work.

DRYING Negatives Quickly.—Some writers on photographic matters appear to have unlimited faith in the virtues of methylated spirit as an agent for the rapid drying of negatives, writes a contributor to the "Westminster Gazette." One such asserts that negatives which have been immersed for two minutes in the spirit will be dry "in two minutes, if the spirit is strong enough." No doubt many readers will share my desire to get hold of some of that spirit. I have tried many kinds of methylated spirit for the purpose of hastening the drying of a negative, but it has never been my good luck to get a brand strong enough to present me with a dried negative in the space of two minutes. If any of my readers have made a note of the quickest results they have achieved in drying negatives in this way, I should be much obliged if they will send along some account of their experience. This question has not received so much attention from our chemical experts as it deserves, for to the professional photographer the rapid drying of a negative is often of great importance. It still remains true that one of the best and safest methods of drying a negative quickly is to place it in a strong current of air, but care must be taken that the air which plays on the surface of the film is not charged with particles of dust.

EDINBURGH University.—Opening the new engineering classes yesterday in Edinburgh University, Professor Hudson Beare, M.Inst.C.E., in an introductory lecture, referred to the purchase by the University for £15,000 of the site of the old infirmary, and said that the block at the north end of the old hospital buildings, including that portion which was originally the High School, had been assigned to the engineering department. During the past summer he had been engaged in the preparation of the preliminary plans in connection with the utilisation of these buildings. These new buildings would provide them with greatly increased accommodation which they were urgently in need of. On the ground floor of the front block would be large lavatories for testing of materials, and for hydraulics, and on the upper floors classrooms, photographic rooms, laboratories for special work, etc. The block of buildings standing behind the main block would be converted into a large lecture theatre, and above this would be a large well-lit drawing office. There was every hope that within the next twelve months the necessary alterations would be carried out, and that by this time next year they might probably be able to move into the new building.

X-RAY Victims.—There are in London, it is estimated, a score of X-ray operators suffering from that mysterious disease which proved fatal in the case of Mr. Clarence Dally, Mr. Edison's assistant. The disease, which is apparently incurable, is set up as a direct result of the manipulation of the Röntgen rays; and the hands of the operator appear to be the most vulnerable part. A fortnight ago one well-known doctor, who is in charge of the X-ray department at one of the largest of the London hospitals, had the first two joints of the forefinger of his right hand amputated, and last Thursday it was found necessary to take the remainder of the finger away. "You can see from the fingers of the right hand how the trouble has developed," he remarked to a "Weekly Dispatch" interviewer. The hand seemed as though it had been severely scalded. It was covered with an ulcerous eruption, and the nails looked as though they had been crushed and torn to pieces. "All the earlier workers," proceeded the doctor, "are suffering in greater or less degree; and this is due solely to the fact that we did not know what we were working with, and took no precautionary methods against possible danger." Mr. Harry Cox, of Rosebery Avenue, who supplies the Admiralty and the War Office with X-ray apparatus, is another of the victims. He carries his left arm in a sling as the result of his injuries.

PHOTOGRAPHY from Balloons.—Miss Gertrude Bacon, daughter of the Rev. John Bacon, the well known aeronaut and investigator, attracted a large audience to the R.P.S. Exhibition at 121, Regent Street, last week by her lecture on "Photography from Balloons and Airships." The clever and witty descriptions which Miss Bacon gave of her many experiences in mid-air and in cloudland were illustrated by a large number of excellent photographs taken by herself and her father while on their voyages. Balloon photography, she said, had very strict limits. It was not possible to obtain sharp results nearer to the earth than 250 ft. or 300 ft., because the ascent was so rapid and the descent had to be carefully watched. On the other hand, good pictures could not be secured at a greater altitude than 2,000 ft. because of the presence of particles in the air which prevented good definitions being made. The views secured at heights varying from 400 ft. to 2,000 ft. were greatly admired, particularly those of London and the surrounding country under various atmospheric conditions. The pictures of cloudland in sunshine and moonlight represented, as Miss Bacon remarked, a veritable fairyland. From ballooning experiences the lecturer passed to descriptions of her airship flights from the Crystal Palace with Mr. Spencer, and claimed to be the first lady to make a long voyage in this manner. Until then she had imagined ballooning to be the best experience in life, but it was as nothing compared with sky-sailing in an air-ship. She looked forward to the time when aerial navigation would be one of the finest sports in the world.

THE Picture Postcard Craze.—Few can question the fascination of picture postcard collecting as a hobby. These pleasing little missives bring to memory sights and scenes almost forgotten, helping one to live again through experience of holiday or travel. The hobby has the advantage over its sister one of stamp-collecting in that the slenderest purses can participate, and being an open field of industrial

enterprise, there are no expensive issues or possible forgeries trouble about. There are a few that fetch prices a little above the original value, such as those taken by the officers of the good ship "Discovery" lately returned from the South Pole expedition; and a few that have been suppressed on political or moral grounds. Governments of various Continental countries. The Russian Government issued an edict forbidding Count Tolstoi's portrait to be used on postcards. The Turkish Government is still more sweeping in its prohibitions; an Iradé forbids any postcard to be circulated bearing the name of God or Mohammed, any drawing of the Kaaba, or any portrait of a Mohammedan woman. In France there is a censorship of cards, and several have been suppressed for offences against good manners. Some time ago 80,000 cards were destroyed as the result of a single raid, and an eye has to be constantly kept on the cards which satirise crowned heads. One card was suppressed for ridiculing the corpulence of the King of Portugal; others for gibes at Prince Henry of the Netherlands and the late Queen Draga of Serbia. The climax was reached when the anti-clerical Government of M. Combes had to stop the circulation of a card as being deficient in reverence towards the Pope. The most intrinsically valuable cards are those that ensure the recipient against accidents for a month for the sum of £50. A series of Dreyfus cards originally published at the moderate price of one and a half francs has since changed hands for £8. Quite probably the famous card said to have been sent by the late President Kruger when the officials wrote to him, after his flight from South Africa, asking for their pay—"Read Proverbs vii. 19, 20"—would command a fair figure if offered for sale.—From the "World's Work and Play" for November.

On Saturday night last a fire broke out at Beavan and Son's photographic studio, Lowther Street, Carlisle. The studio is three storeys high, and is above valuable property. The flames spread rapidly around the top storeys of the block opposite, the General Post Office, and considerable damage was done. The fire brigade and police, however, succeeded in checking the spread of the fire, but the roof of the building was destroyed, and also a large quantity of negatives and photographic apparatus. Damage to the extent of several hundred pounds was done.

J. LANCASTER AND SON, LTD.—This company has been registered with a capital of £10,000 in £1 shares, to acquire the business of a manufacturing optician and importer and manufacturer of and dealer in chemical, scientific, and photographic apparatus, carried on by W. J. Lancaster as J. Lancaster and Son, at 37, Colmore Row, Birmingham, and to carry on the same and the business of electric engineers, makers of and dealers in films, photographic chemists, etc. The subscribers are W. J. Lancaster, C. J. Lancaster, Miss L. M. Lancaster, Miss A. L. Lancaster, E. H. Lancaster, F. J. Heathcote, and A. H. Cox.

TOPICAL Events Illustrated in the Schoolroom.—On Thursday evening last a lantern lecture on the Russo-Japanese war, illustrated by sixty photographic views, was given at the Ricklinghall School, Ipswich, by Mr. W. Palmer to his thirty evening scholars, the parents and friends. The lecturer expressed the hope that as a result of the lecture his audience, which numbered about 100, would be enabled to take a more intelligent interest in the conflict now waging in the Far East. The causes leading to the war, and the description of the views, were listened to with keen interest. On the following evening the lecture was repeated at the Hinderclay School, at which nearly the whole village attended.

TESTS of Potassium Bromide.—Chloride and carbonate, the two impurities most commonly met with in potassium bromide, are both detrimental to its use in emulsion making. Its functions as a restrainer in development are not likely to be affected by the possible proportions of these impurities, and hence the plate-maker rather than the photographer will be interested in the results of a series of tests of bromides, extending over eighteen months, which appear in the "American Journal of Pharmacy." The samples represented six, presumably American, manufacturers, five of whom were found to supply a reliable product. In most cases the titre of the bromide was up to 98 to 99 per cent., in several instances it was as low as 95 to 96 per cent., these bromides containing excess of potassium chloride and showing a strongly alkaline reaction.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
We do not undertake responsibility for the opinions expressed by our correspondents.

THE PHOTOGRAPHIC CLUB.

To the Editors.

Gentlemen,—At the special meeting of the members held last week, it was unanimously decided to terminate the tenancy of the club at Anderton's Hotel, and to remove the headquarters to Huggett's Hotel, 19, Paternoster Square, E.C., and I beg to inform you that in future the meetings will be held at that address on Wednesday evenings at 8.

As it was found impossible to make accommodation for the bookcases containing the library and historical collection, for much of the apparatus and the contents of the dark room, it was decided to dispose of the same, and the committee were empowered to make the necessary arrangements.

Accompanying this is an inventory of the principal properties with the estimated value; should any of your readers desire to purchase any of the items at the prices marked, I shall be glad to receive their applications.—Yours faithfully,

T. W. DERRINGTON,

49, Princes Road, Wimbledon, S.W.

Hon. Secretary.

October 24, 1904.

Property of the Photographic Club with estimated value:—

	£	s.	d.
The library, contained in three bookcases	60	0	0
Pair of optical lanterns, by R. R. Beard; best quality; mahogany bodies with panelled rosewood doors; two pairs of 4½ in. condensers; long and short focus; a pair of Dallmeyer's 6 in. lantern objectives; each is complete as a single lantern, and they may be placed side by side, or used one on the other as a binocular; the fittings include pair of best blow-through jets, dissolving taps, slide tinters, etc.	15	0	0
A 9-ft. opaque screen in lock-up case	1	5	0
A high-class stereoscope, by Beck, with all adjustments... ..	0	15	0
A complete set of Daguerreotype apparatus	1	1	0
Well-made scales, in box; with ordinary and metric weights ..	0	5	6
The well-known collection of Daguerreotypes	1	10	0
Early specimens of photographic enamels, by Lafon de Camarsac and Joubert, in an elegant case by Zaehnsdorf	5	10	0
A revolving album, by Hare			

[We would specially commend the attention of our readers to the opportunities given by the dispersal of the Photographic Club's apparatus to secure some excellent bargains. From long personal knowledge of the items offered, we can pronounce them of good value at the prices indicated.—Eds. B.J.P.]

THE "STEADMAN" EXPOSURE SYSTEM.

To the Editors.

Gentlemen,—What Mr. Watkins says in your issue of September 23 is true concerning the perfect rendering "on one plate" of a subject having foreground, middle distance and bird's-eye planes. But if these conditions exist in the same subject pray how can he assume that I advocate classifying that subject into its three separate parts, calling it three subjects, and giving each part a different diaphragm during the intensity exposure? This would be outside of the possibilities and is foreign to the real reasons for differentiating between foreground, mid distance, and bird's eye subjects.

Supposing that the reader is really interested in the truths that are under discussion I will be pleased to explain as briefly as possible what my opinion is in this matter. In the first place, I class as a foreground subject one which has objects in the foreground which occupy a considerable amount of the visual area of the picture field (for their image, such an area in proportion to the area of the whole image cast by that field). And this whether there are mid distance and bird's-eye planes in the field or not.

A mid-distance subject is one having objects in the middle dis-

tance, but none in the foreground. (It may or may not have a bird's-eye plane.)

A bird's-eye subject is one having neither foreground nor mid-distance objects in it. I think that this classification will be considered logical by all.

Let us consider a foreground subject having both mid-distance and bird's-eye planes as well. Say that the plane in the distance has an intensity of 32 units, the high lights of the foreground, 24 units; the shadows or shade of the mid-distance objects, 16 units, and the half-tone of the foreground objects, 8 units, and its shade, 1 unit. The contrast within the bird's-eye plane is very little, and is what I call "minimum" contrast in studying intensity and its analysis.

There is now a subject confronting the lens which has a contrast factor of 1.32. This contrast is quite within the range of the modern plate and film.

For convenience let us say that to overcome the inertia of the sensitive film is to bring it to that state which will just show a reproducible contrast (when printed) from the "clear glass" plane in the negative during normal development.

Now if this image be allowed to rest on the film long enough to enable the one unit intensity surface to overcome the inertia once, the 32 unit intensity plane will overcome it thirty-two times, the shade of the mid-distance sixteen times, and the high lights of the foreground twenty-four times.

If this latent image be developed to the desired contrast condition for some certain printing medium, that act will locate as desired the highlight and the deepest shadow tones, while the other three planes will assume in the normal development satisfactory positions throughout the scale of tones and opacities.

But suppose now that a small section of the negative, that representing the bird's-eye plane, be cut away and used as an independent negative from which to print a photograph of that particular plane. It is readily seen that although its "minimum" contrast is well rendered as a part of the whole picture, it is too little contrasted to create a satisfactory rendering of the bird's-eye plane alone, if printed as a separate photograph.

Take a parallel case in an artist's hands. Would he treat a small bit of bird's-eye plane occurring in a picture consisting mostly of foreground to the same scale of tones as though the whole picture consisted of a bird's-eye scene? Most certainly not. He is obliged to make his shades or tones "go round" and cannot use them all up in rendering the bird's-eye plane when it occurs as a part of a foreground subject.

For reasons of construction, determined by the most common of common sense, he would also make a painting having a bird's-eye character throughout cover some considerable part of the natural scale of tones.

In all pictures there must be contrasting tones. On this depends the very creation of the semblance of things on a flat surface. There must be drawing there. And the photographic worker must use his chemical actinism in connection with the sensitive film to create a like variety of tone rendering, to agree with the character of the subject to be treated and also to satisfy in an ever-changing variety of manners, his taste.

Suppose that the "minimum" contrast of the bird's-eye plane to consist of values from 30 to 32 units in intensity. While the latter is overcoming the inertia thirty-two times, the former will do it thirty times, the difference in the work done being therefore about seven per cent.

Now reduce the exposure so as to allow the 32-unit plane to overcome the inertia sixteen times, the expressions for the whole series of intensity planes would be as follows:—

Intensities	32	24	16	8	1
Inertias overcome	16	12	8	4	$\frac{1}{2}$

This latent image developed to the same desired contrast factor would spread fewer tones over the tone scale, and the lowest value before detailed would now be thrust down to "clear glass."

Reducing the exposure again by half (which I do by reducing the "speed diaphragms" of subjects as they demand it) the work done by the different planes during exposure would be as follows:—

Intensities	32	24	16	8	1
Inertias overcome	8	6	4	2	$\frac{1}{4}$

Now although these numbers still bear the original relations to each other it must be remembered that one of them, representing the

lowest value, is already sent below the detail line into "clear glass," and that all the effect, with each reduction of exposure, becomes more and more confined to the surface of the film. For this reason, in forcing the greatest effect up to the desired point of density by longer development or intensification the intermediate effects are caused to cling with more and more stubbornness to the opacity of the "glass."

This is simply the effect that undertiming is well known to have on the opacity or tone curve.

By cutting the exposure again in two, the 8-unit intensity plane is enabled to take on the condition before arrived at by the 1-unit intensity. Plus a little further density by reason of the additional development necessary to bring the greatest effect to the required density and the negative therefore to the required contrast factor.

Without carrying the illustration farther I am sure that the reader will understand why a subject having a short range of tones should be allowed to overcome the inertia of the sensitive film less times than the brightest part of a subject which has a long range of actinic intensities in its different parts: Simply that the little differences which it does have may be made to draw themselves with more decisiveness in the negative on development, and thus to spread itself out to a greater range in the tone scale of the photograph.

Notwithstanding Mr. Watkins thinks that actinometers "should have swept (subject classification) away," I am strongly of the opinion that classification is truth's logical handle. I have found it a great help to make the light measurement always the direct explanation of the intensity of the light falling upon the measure, and to think the colour and contrast of the subject and the speed of the plate or film in diaphragm terms. By separating the two truths the mind weaves around them a feeling of greater certainty and confidence, which has greatly aided me in grasping the truths of contrast construction by exposure alone (followed by sufficient development with normal developer).

We seem not to be awake to the poverty-stricken condition of photography to-day! We have no unit of actinism. Actinism is not numerically considered (except in "intensity time" as used with meters, which is not even the beginning of what should be). The brightest professor of physics, if photographing, would simply wonder, if he desired to make a snap shot, whether the light was strong enough or not, and that knowledge, or rather, judgment, would have been derived from his previous experience in "snapping." We have in use no uniform system of either plate speed markings, diaphragms, light, or opacity measurements. And still the average photographic worker wades through the world and really seems proud that after ten or fifteen years of practice and the use of much material he becomes able to do his work with some considerable accuracy. I say he then seems proud, but it is difficult to see why, since any child of school age with any good meter, or any sensitive paper, could learn in an hour or less to expose with a far greater degree of accuracy than such a worker could arrive at in a lifetime. If such a worker had a son who wished to practise photography it seems strange that he should require that son to wade through the years of failure that he went through, thus by actual preference delaying success, and piling up expense, and all for a prejudiced point of view that would be similar to keeping the rule away from the boy, if he were learning carpentry, so that he could the better learn to guess distance. Pray what is this added glory that crowns a dimension, quantity, or an intensity, by having been guessed? Actinism is simply a tool, but is the most important of all the tools of the photographic worker.

It seems to me the veriest of good sense to say that the more we can know of actinism and of all the steps of the photographic process the better and quicker we are able to use these steps for the construction of pictures.

While photography is cursed by the conditions mentioned above, it seems to me a great error on the part of Mr. Watkins to even intimate that there is any over-classification in my bringing the subjects of nature into classes and under logical heads as I have done.

To the worker I will say that it will pay to take the subject list from my first article in the pages of the Journal, and make an effort to really understand the application of it. Not until the meaning becomes clear to the worker is it possible to realise the real intention of the plan or to get the good out of its use.

So far as Mr. Watkins and I are concerned, it is plain that we have

no argument on at the present time. He will say "amen" to the most that I have said, and if I should care to classify nature with greater precision than he finds necessary, that is a small difference between us.

What would be of infinitely greater value to photographic advancement would be for some scientist to explain the absence of simple units of actinic intensity, or for some old school "guesser" to come out and take a stand for his hobby and explain the benefits of "not knowing" his tools.

It would also be interesting for some prominent plate maker to take up the justification of the stand that there should not be a uniform method of plate speeding or marking adopted, and for some manufacturer of lenses to explain why there should be half-a-dozen diaphragm scales in existence.

It would also be of interest to have some educator explain the absence of photography from the public school course.

Also, with all the searching for effective kindergarten work, how is it that a child grows up without the least idea of the actual duration of a second of time, when the use of a simple phrase will allow any child to have under perfect control, the quarter, half, and full second, and any number of seconds?

Also why is it that the shutter makers insist on giving a scale of speed intervals that do not agree with the needs of the diaphragm openings as they enlarge? For example: If diaphragm F. 32 should, in a certain case, require one second of exposure, the relations of diaphragms to exposure throughout the larger openings would be as follows:—

	F. 32	F. 22	F. 16	F. 11	F. 8	F. 5-6
Exposure ...	1 sec.	$\frac{1}{2}$	$\frac{1}{4}$	$\frac{1}{8}$	1-16	1-32

Will some shutter manufacturer please teach us the benefits of having the speed intervals of the shutter not agree with this need of the diaphragms?

The discussion of these things would lead into interesting and important paths. I am, sir, sincerely yours,

New York City,

R. M. STEADMAN.

October 15, 1904.

NOTHING LIKE BUTTONS.

To the Editors.

Gentlemen,—Referring to Messrs. Medrington's letter in your issue of October 21, the concluding paragraph of which reads, "Obtaining the high profits 'Argus' hints at, out of promenades at 8s. 6d. per dozen, must mean Sunday work, low salaries, and sweating for the employees." In proof of this, it is only a few months back that your paper contained an account of a 'cheap' photographer who was fined for working girls long after business hours," and which I believe refers to myself. I would like to offer a few words of explanation.

I do not make a high profit out of promenades at 8s. 6d. per dozen, and have no need to overwork, underpay, or otherwise illtreat my assistants. My assistants do not work on Sundays, their hours are not long (I believe they are identical with Medrington's), and they are not sweated; the only exception to these statements being that during the fortnight preceding Christmas (a very busy time) four of them worked extra time after six o'clock, and for a period of four hours on the Sunday, and for this I was fined.

I certainly thought that payment of the fine ended the matter, but Messrs. Medrington evidently think otherwise, and now perhaps they will state that they themselves did not work overtime at the same period, and so become equally liable to a penalty.

Assistants do not voluntarily leave my employment, in proof of which I may state that all the assistants engaged by me from the day I commenced are still with me. I can confidently join issue with Messrs. Medrington that my workers are as well paid, and have as easy hours, as those engaged in any other properly managed photographic business in this city.

As regards the "cheapening" of photographic work in the public estimation, I do not consider that a reasonable price cheapens the work so much as the methods employed by some firms to secure business. Messrs. Medrington are a firm who issue free invitations by the hundreds, and even give away enlargements. These are undoubtedly means of "cheapening" photographic work, and I, for one, have never descended to this level, and do not intend to do so.

It may hurt Messrs. Medrington to know that I can do good

work at a low price and still manage to make a little profit, but proper up-to-date management is the explanation, and no free sitting trickery.

I am not a "cheap" photographer. I have a special line at a low price; but the class of my work will not permit of an all-round reduction in prices, and my prices have not been reduced since I commenced business nine years ago.

In conclusion, I consider that a firm of the reputed standing of Messrs. Medrington are demeaning themselves sadly when they descend to the level of mud-throwing.—I am, Gentlemen, yours truly,
E. T. VANDERBILT.

Liverpool, October 24, 1904.

To the Editors.

Gentlemen,—As one of your constant readers, I would like to point out that your correspondent, who signs himself "Argus," is talking of something he knows very little about. Is he aware that there are a great number of first-class men who have taken up the three cabinets for 2s. 6d. and promenades at 10s. 6d. the dozen, and which are equally as good as those who charge a guinea, and by giving his clients good value can smoke the "big cigar" and ride in a "motor car," and also put by enough for the so-called (rainy day) without sweating his employees? I might point out to him that there are P.R.S.'s who are guilty of this terrible offence, and why in all conscience the photographer that does honest work at the above-mentioned prices is so ridiculed by a member of the profession (which I doubt he belongs to) is beyond me. There are many firms in London where "Argus" can have a portrait taken at the above prices that would probably astonish him. Move with the times is the advice of yours, etc.,
ONE OF THE MUSHROOMS.

THE P.P.A. EXAMINATION SCHEME.

To the Editors.

Gentlemen,—The tentative scheme of the Professional Photographers' Association for granting certificates to employees must, I think, be regarded by employer and assistant alike as a step in the direction of a long-needed reform. To the employer it should furnish an approximate criterion of an assistant's capacities before entering into an engagement, the result of which might be otherwise disappointing. And, further, no competent assistant who is honest will object either to undergo examination or to have his record inquired into. Thus the employer will be safeguarded to a very fair extent. As, however, the secretary of the association invites criticism of a constructive nature, may I venture, in meekness and with much fear and trembling, to suggest that the scheme should also embody some provision for safeguarding the interests of the poor assistant after he has undergone the ordeal of the cross-examination which appear to be involved. Assuming that he emerges whole and sound and with, it may be, flying colours, what is there to guarantee him anything approaching security of engagement, or against certain frictional disturbances resulting partly from inconsiderate exigencies and caprice of temper on the part of his employer? Apparently he is still liable to be dismissed at a week's notice for causes which may be outside his control, such as, for instance, business depression, competition in salaries, or he may have to consider the alternative of long hours, sweating, gratuitous overtime, or an amazing versatility in his requisite accomplishments. Of course, no employer who enjoys even a moderate reputation would dream of placing himself at such an ultimate disadvantage as the non-observance of the golden rule would bring about. But there are others. Therefore, since it is proposed to reduce to a minimum the chance of imposture by the incompetent, may not one justifiably ask that there should also remain as little risk of the conscientious being imposed upon. It has occurred to me that a form corresponding to that it is proposed to employ for assistants might in some cases be used with advantage in the case of employers. I would also beg leave to suggest that any employer who avails himself of the proposed scheme, that is, in requiring candidates to produce a certificate or to undergo examination, be prepared to offer a yearly agreement to his employees. This would, in my opinion, certainly tend to diminish whatever of friction there may at present exist between those whose interests are, after all, mutual, if they could

only see it. As I do not desire to shelter myself anonymously, I beg to subscribe myself, your faithfully,
G. F. A. FRANKLIN.

47, Castle Street, Bolton.

SOME PECULIARITIES OF DYES WHICH PRODUCE TOTAL SPECTRUM SENSITIVENESS.

To the Editors.

Gentlemen,—Obviously Mr. Thorne Baker is exceptionally sensitive to criticism, and would have one and all of us accept the results of his original (?) research as gospel, and without criticism or question, even when those results are entirely opposed to the results obtained by men who have had thirty years' experience in the particular subject.

Had your correspondent chosen to drop rude personalities and discuss the subject I might have been induced to publish some of the results of my own experiments (I do not call them "original research") to prove that he is wrong. But, Gentlemen, I have lived long enough to outlive the youthful desire of self-advertisement, and the childish disease of *cacoethes scribendi*.

"The much overdone German" is a worm to be despised when his results do not accord with your correspondent's, but the dyes used, the instrument employed, and the principle involved all originated with "the much overdone German."

Your correspondent is at liberty, so far as I am concerned, to fill your pages, and the pages of every other English journal, photographic or otherwise, and when he attains this height in the near future, I shall content myself with those of the despised Teuton, where I can get original matter that is worth reading.—Yours faithfully,
E. J. WALL.

Foot's Cray.

TANQUEREY IN ENGLAND.

To the Editors.

Gentlemen,—In last week's issue of your paper a correspondent draws your attention to the fact that Tanqueray is now working the free portrait swindle in Ceylon. This is due no doubt to competition in England. At the present time Bedfordshire and Buckinghamshire are being freely worked by the free portrait gentry, who send round women canvassers, that force themselves "by sheer cheek," into the homes of country people and get hold of some sort of photograph which they will enlarge free, just for advertisement, as they put it. In some cases a handbill is found stating that it will be necessary to buy a frame. This is usually found long after they have left the place. Nothing more is heard until the framed picture is brought home and the money demanded, this time by a man, with threat of a summons if they dare deny payment. The usual charge is 25s. to 30s. for framing. One of the daily papers once stated that if Tanqueray were in England he could be proceeded against. Tanqueray did give his victim the option of leaving the lot when they knew they were had. But these gentry of Leighton Buzzard simply force the thing on the unsuspecting public.—Yours faithfully,
A. T. BURR.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

	s.	d.	
One Year	10	10	France, Belgium, United States, Canada, Australia, Africa, New Zealand, Newfoundland, Germany, Russia, Portugal, Spain, Italy, Egypt, India, China, Japan, &c. One Year ...
Half Year	5	5	13s.
Quarter Year	2	6	

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

Answers to Correspondents.

- **All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- **Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- **Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*
- **For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- J. Weir, Burn Cottage, Well Road, Moffat. *Photograph of Old Black Bull Inn, Moffat.*
- Grant & Pickeman, 7, South Guildry Street, Elgin. *Three Photographs of the Rev. R. Cowan.*
- F. Aspden, 48, Church Road, St. Anne's-on-the-Sea. *Photograph of St. Anne's-on-the-Sea Telegraph Messengers.*
- E. Lippiatt, The Beach Studios, Clevedon, Somerset. *Two Photographs of Rough Sea at Clevedon, August 15, 1904.*
- B. and W. Fisk-Moore, 4, St. George's Gate, Canterbury. *Photograph of W. J. Fisher.*
- W. H. Hoare, 68, Oxford Street, Swansea. *Five Photographs of the G.W.R. Disaster near Llanelly.*
- P. Wynne, 518, Coventry Road, Small Heath, Birmingham. *Two Photographs of the School Children at the Opening of Small Heath Bridge.*
- A. J. Piper, 6, Cotton Road, Nuneaton. *Photograph of Nuneaton Conservative Club.*
- S. A. Baker, 118, London Road, Southborough, Kent. *Photograph (Interior) of Old Oak Room, George and Dragon Hotel, Speldhurst, Kent. Photograph of the George and Dragon Hotel.*
- D. Whyte, 57, Church Street, Inverness. *Five Photographs of Glenquoich Lodge, Inverness-shire. Two Photographs of the King. Two Photographs of the King and Party.*

APPRENTICESHIP.—"INDENTURE" writes as follows: "In the event of a photographer having to dismiss an indentured pupil through the pupil's misconduct, do the clauses of the indenture hold good, say in the matter of his starting in opposition?" In reply: This, we imagine, will depend upon the wording of the indentures. The question should be referred to a solicitor with the indentures.

RESIDUES.—"C. W. Y." says: "I should esteem it a favour if you could let me know if the cuttings from collodion chloride papers are worth retaining for the silver they contain?" In reply: At the present price of silver, unless you use a considerable quantity of the paper, the cuttings are scarcely worth the trouble of saving. If, however, you save your other wastes, these should be added to them.

THE VERANT.—A. MASSER writes: "Will you kindly inform me if there is any further information re notes concerning Dr. Moritz Von Rohr, contained in the last paragraph on page 671 of last year's B.J. ALMANAC, concerning stereoscopic photography, in which I am deeply interested, or could you enlighten me further on this subject?" In reply: Our correspondent will find full particulars in the forthcoming ALMANAC.

MATERIAL FOR BACKGROUNDS.—PEMBERTON BROS. ask: "Will you please inform us where we can procure canvas up to 8 ft. wide as enclosed sample, and you will greatly oblige?" In reply: Sheetting up to 8 ft. wide may be obtained from most of the large drapery and upholstery stores. The latter may possibly supply canvas that width, inquire of them. If you read the notice that heads this column each week you will see that we do not reply to correspondents by post.

COPYRIGHT QUERY.—A. J. STONES says: "I should be glad to learn if the copyright of the lantern slides of the Columbian Exhibition, Chicago, 1893, has expired, and if I may reproduce them for trade purposes." In reply: If the pictures were registered according to the English Copyright law, the copyright in them lasts during the lifetime of the author, and for seven years after his death. Whether he is still alive, or, if not, when he died, you must find out yourself.

COLOURING PHOTOGRAPHS.—M. WALTON asks: "Will you kindly tell me what special preparation of colour you would recommend for colouring photographs apart from dyes, both bromides and

silver prints; and also if the photographs should be prepared in any way before colouring?" In reply: Ordinary water colours are what are usually employed. No preparation is necessary, but should the surface of the photographs be at all repellent of the colour, they may be washed over with very dilute ox-gall. Prepared ox-gall is sold by all the artists' colourmen.

STAINED NEGATIVE.—WALTER WELLS writes: "Through inadvertence printing before the negative was perfectly dry a print (P.O.P. paper) stuck in one corner. In order to remove it I soaked it, and succeeded in getting it off without damaging the film of the negative, but it has left a nasty ruby-coloured stain the size of a penny. My trouble is how to remove the stain, which copious washing does not touch." In reply: Stain of this kind is very difficult of removal without leaving a mark or damaging the other portions of the negative. Soaking it for a long time in a new solution of hyposulphite of soda.

BURNISHING.—"PERPLEXED" asks: "Will you kindly inform me the reason why some P.O.P. prints do not burnish evenly, and some not at all, while others do? Also tell me the correct heat and pressure to use, and anything to remedy these faults. I have used castile-soap dissolved in alcohol. I use a Tylar's burnisher." In reply: If the prints that do not burnish evenly were dealt with the same as those that do, the results would be the same. Make the burnisher as hot as the hand can bear, and apply sufficient pressure to get the gloss desired. We should advise you to get some one who knows how to use a burnisher to show you how to use yours.

LENS QUERY.—MARK DRAPER says: "(1) I want a cheap lens to give a very wide angle of view on a whole plate. Would you kindly tell me if either combination of a quarter-plate R.R. (cheap) would do this with a moderate stop, say $f/22$? If a half-plate W.A. lens would cover to the edges? Stop down will not matter, as it is only for interiors and exteriors and not for groups, etc." In reply: (1) Something of the kind must necessarily depend upon the quality of the instrument. But supposing one of the combinations will cover a whole plate, the angle included will not be wide. (2) This can only be ascertained by a trial of the lens.

SOLAR ENLARGEMENTS.—"INQUIRER" says: "I should esteem it a favour if you could answer me the following: (1) Can solar enlargements be made with the same camera and in the same way as bromide? (2) Can they be made by artificial light such as bromides? (3) Could you give me the address of any one who does them for the trade?" In reply: (1) No; you require a condenser and the means of causing it to follow the sun as in the solar camera. (2) Yes, with the arc light and very long exposure. (3) So far as we are aware there are no firms in England that employ the solar camera. Sunlight can be depended upon here, the weather is too uncertain.

PORTABLE STUDIO.—"CARAVAN" asks: "Is there any legal limit as to the size of a portable studio on wheels? If so, what limit should such a studio as large as conveniently possible. What would be the best all-round size, length, width, and how much glass required in comparison to size of studio? A small studio would be required for dressing and dark rooms respectively. The camera would be worked from between the two rooms per sketch enclosed." In reply: We are not aware that there is any legal limit as to size. A convenient size for working about 25 ft. by 10 ft. or 11 ft. The end of the studio, as from the dark and dressing rooms, may be opaque for about 4 ft., and from there to the rooms may be glass.

SPECIMENS.—"P. W." writes as follows: "A photographer in my locality, whose work is of the 'cheap and nasty' order, has lately been taken to showing work in his window of which he is not the author, with the evident intention of deceiving the public. The idea that it is his own work. The work is of quite a high class West-end style, and the name on the mount has been carefully erased. He has now six framed direct whole plate and two enlargements of this kind, and I fear an injury to my business through this deception. Is there any redress means of putting a stop to this kind of dishonest practice?" In reply: So far as we are aware there is no law that will prevent your opponent doing as he is. The proceeding is certainly not creditable to him.

EX CATHEDRA.

A New Photo-Chemical Change.

An addition to the list of photo-sensitive compounds is made by W. A. Kistjalkowsky before a recent meeting of the Russian Chemical Society in St. Petersburg. The author finds that a mixture of mercuric chloride and oxalic acid, which in the ordinary course is sensitive to light to a minute extent, becomes strongly sensitive on addition of a little manganese peroxide. A mixture of these substances is decomposed in sunlight at once, mercurous chloride (calomel) separating. In place of the peroxide a few drops of potassium permanganate solution can be used. The reaction suggests possibilities in the way of photographic applications. Calomel is a body entering into a number of chemical combinations, and it is possible that for purposes of intensification or printing the reaction may be of service.

* * *

Potassium Cyanide.

A new fact of some direct bearing on the use of potassium cyanide as a fixing agent is brought to light in a series of papers in the "Annales de Chimie et de Physique." The author, M. Berthelot, has investigated the slow absorption of oxygen which takes place when solution of potassium cyanide is confined with that gas for a considerable space of time. The gas combines with the liquid to a marked degree, and it cannot be supposed that it does not do so when the cyanide solution is exposed freely to the air although the oxygen then only forms the fifth of the gas in contact with the surface. M. Berthelot shows also that the absorption is much greater in a strong light than in the dark, and is greater also the warmer the solution of the cyanide. Although the poisonous properties of cyanide have almost banished it from the fixing tank, many a photographer working the wet-plate process still clings to it, and it may therefore not be out of place to point the moral of M. Berthelot's researches—which is that protection from air, light, and heat, will assist in preserving its activity.

* * *

Photographing A Parisian medical newspaper draws the Dead.

attention to a proposal of Bertillon's which adds much to the value of photographs for identification of the dead. Those who have seen the photograph of the corpse of some person they have known have doubtless been struck by the vast change in appearance in comparison with the remembrance of the living being. So great is it that the photograph is often unrecognisable. Bertillon's proposal is to inject three or four drops of glycerine into the eyes with a syringe. The effect is said to be astonishing. The lids open wide and remain so, and the body again assumes the appearance of life.

B

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

The forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies.

The growth in popularity of the ALMANAC is evidenced by the remarkable rapidity of its sales.

The 1900 Edition (20,500 copies) was sold within three months after publication.

The 1901 Edition (20,500 copies) was sold a fortnight after publication.

The 1902 Edition (20,500 copies) was sold a fortnight before publication.

The 1903 Edition (25,000 copies) was completely ordered before publication.

The 1904 Edition (25,000 copies) was also completely ordered before publication.

* The frontispiece of the ALMANAC will consist of a portrait study specially taken by Mr. Furley Lewis (medallist of the Royal Photographic Society's Exhibition, 1903).

The dull appearance of the eyeballs is removed by dropping a few drops more glycerine upon the cornea, and the colour is restored to the lips with carmine. The transformation of appearance is then complete, and the photograph of the corpse will resemble that of the living person. These proposals were made to facilitate the identification of bodies for the ends of justice, but they may be of considerable value to the photographer. Many have a strong objection to submit themselves to the camera, and their relatives not unfrequently wish even for the photograph of the person's body after death. The means suggested by Bertillon would probably help to make such pictures less ghastly.

* * *

Colour Photography. Our French contemporary, "Le Moniteur de la Photographie," publishes a translation by M. Sabatière, of Mr. Henry Collen's outline of a scheme of trichromatic photography, which appeared in this newspaper on October 27, 1865. The editors of the "Moniteur" rightly point to it as an historic document, and although the views expressed in it by Mr. Collen are open to criticism, it shows the penetrative power of thought the writer had in this, besides other branches of photography. In the able lecture on "The Optics of Trichromatic Photography," which Mr. F. E. Ives delivered for the Trill Taylor Memorial, this speculative theory of Henry Collen's is also mentioned. According to Mr. Ives, it was the next published suggestion of a trichromatic process after the lecture of Professor James Clerk-Maxwell in 1861; but whilst Mr. Ives has good reasons for thinking the latter was scientifically correct, he offers the following criticism of the Collen process:—"There were three defects in this proposition, any one of which would have been fatal. First the wrong idea as to the primary colours. Second, the fact that prints in true red, yellow, and true blue cannot be made to even approximately reproduce all colours. Third, that the combination of two negatives doubles the opacity of all whites and greys, without altering the opacity of the records of the pure colours."

* * *

Photographic Post-cards. The "Moniteur" also draws the attention of its readers to the enterprise of a Parisian photographer in the printing of amateurs' negatives as post-cards. Nowadays the camera is found almost in every household with pretence to education. We take our cameras with us wherever we expect to find the beautiful or the interesting. What becomes of most of these negatives? After a few prints have been made they are laid aside, and, much as we may like them, they rarely come to light again. The post-card is in the height of fashion, and the quarter-plate camera lends itself admirably to the production of post-cards. The Parisian photographer has seized upon this idea and makes it known that he will make one hundred post-cards from an amateur's negative for the sum of 5 francs. The winter months bring hardship to many photographers, but we have here an idea which might help many to pull through the bad time and lead them to something better. An arrangement for quickly printing in bromide may be constructed at little expense, and a price should be obtainable which should give fair remuneration to the man of ordinary business ability. The supply of the amateur's other wants might follow.

* * *

Abuse of Untoned Proofs. At the last meeting of the Professional Photographers' Association reference was again made to the large number of untoned proofs submitted by photographers to their sitters, that were systematically taken to dealers and others to be toned and

mounted, and, of course, utilised by the customer to the loss of the photographer. It has been suggested that all proofs should be stamped across the front, near the face, with the name of the photographer issuing them. A better way, perhaps, would be to stamp them with the words "unfixed proof" or "unfixed proof to be returned." It occurs to us while writing that this method might be still further improved upon by a modification of the ink used with the endorsing stamp. Iron-gallate ink would be more indelible than that usually employed with rubber stamps. Or perhaps a reducing agent, such as a strong solution of hypo or pyrogallol acid, might be added to it. If this were done, it is very probable that in washing out the free silver, prior to toning the print would be so stained or blackened as to be useless, as would possibly others washed in the same water. If some such plan as this were adopted the photographer, even if he did not get his proofs back, would have the satisfaction of knowing that they would be useless to anyone else, and no offence could be taken by the customer. The reducing agent might be applied in a strong solution to the inking pad of the rubber stamp. We throw out this hint for what it is worth, because it is very desirable that this growing evil should be put a stop to in the interests of the profession.

* * *

Storing Apparatus During the Winter.

November is now with us, and not a few photographers will be relinquishing outdoor photography for some few months to come. Now upon the care bestowed upon the storage of the apparatus during the winter months will, in great measure, depend the condition in which it is found when next required for use. It is no unusual thing for the apparatus to be relegated to the lumber-room, which is frequently situated at the top of the house. Attics, as a rule, are exceedingly hot and dry during the summer months, and just the reverse during the winter ones, unless they occasionally have a fire in them. As a consequence when the things are unearthed in the spring they are often found to be in a quite unworkable state until some time has been expended upon them. This would be quite unnecessary if a few precautions were taken at the end of the season. In the first place, the apparatus should be stored in a perfectly dry place. Damp causes the woodwork to swell and the metal portions (open) to corrode, especially steel springs and the like, which sometimes, in bad cases, have to be renewed. Before the apparatus is put away it should be thoroughly cleansed and dusted, and if the bellows of the camera has shown any tendency to stick together when in use, it should be well rubbed over with French chalk before it is put away. The tension should always be taken off the shutter spring, as unless this is done the spring will, with the long tension upon it, become weakened, and the shutter will not work at the same speeds as it did originally. If the camera is not provided with a case it should be packed in paper to protect it from dust. Even if it has a case, it is a good plan to pack that in paper as a further protection against dust. When these few timely precautions are taken, and they do not involve much trouble, the apparatus will, when next required for use, be found in the same condition as when stored away. It will also be ready for immediate use in a case of emergency should one arise.

The Cost of a School for Photography.

The habit, which Englishmen have latterly acquired, of looking to Germany as a leader in the art of technical education, may cause them to make a leap in the dark, which they may bitterly regret when afterwards they are burdened with

the consequent expense. The glib answer so-called reformers give—that the State must pay—seems so satisfactory to the unthinking taxpayer that he believes that he is getting something for nothing, until the bill is tendered at the end of the year in the demand for additional taxes. A very instructive article on the cost of these technical schools in Germany appeared in a recent number of "Photographische Kunst," and the figures it gives for some of these establishments are very interesting. A Mr. Wandrowski has advocated the establishment of other schools of photography. His estimate is that the cost of the building for 100 students would be about £5,000 and the annual outlay £1,000. The primary cost should be met by photographers and other interested persons (by special taxation?) and the students should pay £15 per annum in fees. "Photographische Kunst" is the organ of the Munich Photographic School, and inexorably points out that Mr. Wandrowski's budget has been prepared by the aid of rose-tinted spectacles. The scheme, if carried out, would end in an annual loss of £1,300 per annum. Now we put it to the photographers—Is the result worth the cost? In this country the cost of the buildings would fall upon the State or the municipality. At 3 per cent. per annum this would be £150, and to this we must add the deficit of £1,300, which would make a total of £1,450 per annum for turning 100 men each year into an already overcrowded craft. It must also be borne in mind that this is independent of the outlay of the students in fees, board, lodging, etc., and that this calculation is the cost "made in Germany." If the profession is to attain a remunerative position and preserve it, no demands should be made for State or other subsidies, which would only attract further competitors to an already overcrowded means of livelihood. A further depression of prices would follow. Neither is it right that the taxpayers should be unnecessarily burdened with the cost of teaching young men their business, thus relieving masters of their duty to train their apprentices. No wonder so many German photographers find it difficult to keep body and soul together!

Picture Post-cards.

In our last issue we directed attention to a circular issued by the Postmaster-General calling the attention of producers of picture post-cards to the limits of sizes according to the postal regulations. Last week a reply which was sent by the Postmaster-General to Messrs. Raphael Tuck and Sons, the well-known publishers of picture post-cards, enclosing petitions from several other publishers, was published in the daily Press. In it the Postmaster-General says he is aware that considerable annoyance is caused to members of the public by the surcharges which have to be made upon the delivery of picture cards exceeding the prescribed limits of size—viz., 5½ in. in length and 3½ in. in width, but he does not consider it desirable to adopt the changes suggested, namely, the addition of the ¼ in. in the width allowed, since in that case the cards made the full size allowed for the inland post would be liable to be surcharged when sent abroad. He says, however, that in response to the representations made by them and other publishers he will give instructions that, for a period of six months, post-cards that exceed the prescribed dimensions by not more than 1-16 in., and are otherwise in conformity with the regulations, shall be allowed to pass without challenge. The Postmaster-General adds that in sanctioning this temporary concession he relies upon publishers to use their best endeavours to conform strictly to the prescribed dimensions with as little delay as possible. It will be noted that this concession of the sixteenth of an inch is only temporary, and is evidently made to enable publishers to

dispose of their present stocks, and we should advise photographers who print their own picture post-cards to make note of it, and if they have any on hand exceeding the regulation size to cut them down to it before selling them. The sixteenth or the eighth of an inch even will in most cases not make a material difference in the appearance of the picture. Anent postal regulations we mentioned in our previous issue that nothing must be attached to a post-card. We see the reply given by the Postmaster-General to a gentleman who complained that he had been surcharged threepence on a picture post-card he had received from Spain which was decorated with a slight amount of tinsel. The reply, in effect, was that under the regulations of the Postal Union nothing must be affixed to a post-card sent from one country to another. "In contravention of this regulation the enclosed card has been ornamented with tinsel, and it was therefore rightly taxed as an insufficiently paid letter."

An Emperor on Art.

When a King speaks, everyone is prepared to listen to him, and we may feel sure that the Kaiser's recent utterance on the subject of Art will not go unheeded. The Emperor of Germany busies himself about so many different things that he may be fairly called a Master of Arts, albeit an unkind critic might suggest that a jack of all trades is proverbially unfit to claim that distinction. But all will agree that Germany's present ruler is a most capable man, and proves by his speeches that he has an ample store of that uncommon quality which is misnamed "common sense." On the recent occasion of unveiling a statue to the memory of his revered father, he ventilated his opinions on Art generally, and as, contrary to his usual custom, he read from a manuscript, we may feel sure that his words had been carefully weighed beforehand. Germany, like most other countries, has her secessionists among the artists, men who are ever ready to break away from the old methods and traditions which have been handed down from one generation to another, and the Kaiser believes that they are following false roads, which are leading them far remote from true ideals of beauty. It was the study of the old masters, he said, which was the right introduction to the study of the problems of art, and he urged young artists to imitate the self-criticism, the modesty, and the respect for the work of others which characterised the masters of past times. He made no mention of photography, but we all know how the work of the modern photographer is influenced by that of the painter, and not always for the better. Impressionism in painting, which very often is an excuse for bad drawing, and always ignores detail, has its reflection in much of the modern so-called "pictorial work" of the photographer. We have no objection to impressionist pictures *per se*, and have often seen much in them to excite our admiration. And anyone who has any feeling for Art will take the keenest pleasure in looking through the half-finished sketches of a capable artist—just in the same way that a trained ear will listen with intense enjoyment to a musician who has the rare gift of improvisation. But the sketches should be kept for reference, and the improvisation confined to the practice room! When the artist comes before the public he should, in either case, only offer his finished work for approval. Many of the "pictorial" photographs now exhibited should be kept in a portfolio as experimental notes and curiosities, but to show them in public as specimens of what the exhibitor can do, is a grievous mistake. There are fashions, and tides of fashions, in all things, and very possibly the present craze for the vague and ill-defined will pass away in favour of some other fad. As we look through

a collection of old fashion plates we find many which raise a hearty laugh, but they were taken quite seriously when they were in vogue. It may be the same some day with the advanced school of pictorial photography.

* * *

Landscape Studies.

A great change has come over photographers in the kind of pictures which they send up for exhibition. Time was when any photographic show could easily be sorted into two main divisions—portraiture and landscape. The portraits are still with us, but landscape seems to be neglected. Photographers, like other mortals, are apt to imitate one another's works, and to run for a time in one groove. At one time landscape pure and simple was in vogue, and every one did landscape. Then cottage doors and cottagers came in for a time. Another period saw the mud flat, with cloudy sky, come into prominence, until it was thrust aside by ships and barges, with long straggling reflections in troubled waters. The fortunate man who started one of these types, and won a medal at some show, had hosts of imitators, and so a usage was established which, for a time, was run for all it was worth. We need say nothing about flower studies, kittens, puppies, and pet animals generally, for they, like the poor, are always with us. It is the disappearance of the simple landscape that we deplore; we mean the kind of subject which Turner, the painter, had he been a photographer would have gone for. We can easily imagine how the author of the "Liber Studiorum" would have delighted in an instrument which would secure effects in one second which cost him hours to express in sepia. In those pictures Turner showed what beauty there was in simple form and monochrome, and we may feel sure that he would have appreciated a method in which the form is faultless, and in which monochrome is a necessity. Photographers are naturally guided by the popular taste, and many of them, like other business men, are bound to be so. If they complain, as they might reasonably do, that the popular taste is a sorry guide for it is generally bad, and resolve to go a better way, they quickly find their occupation gone. The truth is that an appreciation of the beauties of pure landscape is a rare gift, and like a keen perception of colour, or a recognition of subtle harmonies in music, cannot be taught. It is like the appreciation of poetry, a birthday gift, and happy is its possessor. Still, we think that if some leading worker would come forward and show what can be done with simple landscape, and devote his attention to broad effects of hill and dale—and our country offers endless opportunities for such pictures—his work would attract notice. For it is a curious thing that the majority of people will take no note of a beautiful effect in Nature—say a sunset—but will at once admire a picture representing the same thing. Of course, the picture comes immeasurably short of Nature, but it compresses the scene within small limits, and minds of limited accommodation are able to take it in. We plead for a revival of pure landscape photography.

* * *

The Lantern Season.

Although the lantern show is not so popular as it used to be before the cinematograph put its nose out of joint—to use a common phrase—it still holds its own for the more serious business of the lecture theatre, and will always be in evidence at meetings of photographic societies. And there are signs apparent in the catalogues of manufacturers and dealers that they at least are looking forward to a prosperous lantern season, although no one expects the boom in lanterns which came a few years back. Although there is no great change in the form of the instrument, several improvements are noticeable in details of construction, which tend

both to portability and convenience of working, and may say that further improvement is almost impossible with materials at present available. While the makers are thus doing their best to maintain the high position of the lantern as a means of demonstration, would it not be as well if the many lecturers who make use of it before the public were to endeavour to improve both their method of delivery and the arrangement of their subjects? There are men whom it is a pleasure to listen to, so well do they understand the art of public speaking, and such as do they devote to marshalling their facts, but it must be confessed that the majority of those who speak before societies cannot be thus described. And unless a lantern lecture is of really good quality it is a most deplorable thing to listen to. The art of speaking effectively to the public is only acquired by a small minority—and many who try hard to conquer its difficulties never succeed in doing so. We know several estimable men who, with the qualification of a few letters after their name, are not qualified to speak in public. But they go on lecturing time after time, and have no idea of the sufferings of the audiences. If they are methodical in the arrangement of their subject-matter it is some compensation, but too often they disdain any arrangement at all, and will often commence their remarks with an apology for not having had time to sort or number their slides. The best lantern in the world and the best slides will be of little good under such conditions, and although it would be bad taste to heckle a man who at some inconvenience to himself has volunteered to appear before a society as a lecturer, the audience does not fail to express its opinions in private on the lamentable performance. Such careless ones really do more harm than good, for the patient listeners are induced to register a vow that never again will they be tempted from their firesides to undergo such an ordeal. And so the meetings of our societies get sparse attendances, whereas if the lectures were of better quality, people would be anxious to come again and again. At the beginning of another lantern season we therefore express the hope that intending lecturers will do their best to take away this reproach, and that they will endeavour, by paying more attention to their matter and manner of delivery, to make their audiences wish to hear them again.

SUPPLEMENTARY LENSES.

II.

It has been suggested that, as in the use of the separate halves of a double lens, though constructed to be complementary, they may be considered as supplementary, might refer to them more fully than in our previous article under the above heading. As a matter of fact, such further remarks should not be required, as most optical properties possessed by the whole. Thus we have, first, the fact that, with a given stop, the exposure is quadrupled with the halves of symmetrical doublets, and proportionately more or less in unsymmetrical lenses as the respective foci vary. Next, we have the condition of the half combination, usually being of the ordinary "landscape lens" type, that is to say, with a curved field giving distorted marginal lines. There is, however, a type of lens on the market whose halves give a practically flat field. And with regard to marginal distortion of straight lines this is so small as to be almost imperceptible when a lens with a focus much exceeding the length of the negative

employed, the images occupying the centre of the field. This condition would almost always obtain in the case of an ordinary doublet. A 5 in. focus lens, for example, is a common minimum for quarter-plate pictures, and, taking the half to be approximately 10 in., we unhesitatingly say that a building might be taken so as to occupy the whole of the plate, and yet not give a distortion that could be measured on a print. Even with a lens whose components had foci in the proportion of 2 to 3, the shorter focus of the two might be used for architectural work without anxiety—even for interiors—if the axis of the lens passed through the centre of the plate. There is, however, one important point which is so rarely referred to in this connection that we feel it necessary to allude to it. We do not hear much of "flare spot" nowadays; but its possibility exists, and, indeed, we often see instances of it; that it is much less often seen in double than in landscape lenses may account for this, seeing that even cheap instruments have doublets of greater or less efficiency. But to return to this half-lens's possible defect. Flare arises through the diaphragm being wrongly placed; a few turns of the lens in its socket may suffice to put it right. Should that not be sufficient, a supplementary tube screwed to receive the half-lens should be carried so as to be able to lengthen the lens case sufficiently to avoid flare. We may dismiss this branch of the topic by saying that it is very unfortunate that in the case of a particular camera on the market which has one of the largest of sales the lens supplied cannot be used when thus halved owing to the bellows extension being insufficient.

This point brings us again to the true supplementary lens, and is just an example of its usefulness. It is true a long focus lens is obtainable for this particular camera. But it may be that its owner does not care to go to the expense its purchase would entail. Sixpence or less will buy a lens that will help. A supplementary lens of fairly long focus will so shorten the half-lens focus that the camera will be available. What the focal length of the supplementary should be is simply calculated. Take a 6 in. lens, whose half would be approximately 12 in., and a camera extension, say, of 11 in., an 11 in. focus would be required for distant objects, but would not answer for anything near. Let us decide upon a 9 in. focus. The question then is: What lens should be used with a 6 in. to make it into a 9 in.? If we take the reciprocals of the two numbers, 6 and 9, and subtract, we shall obtain a fraction containing the required information. Thus— $\frac{1}{6} - \frac{1}{9} = \frac{3}{18} - \frac{2}{18} = \frac{1}{18}$. This fraction is the reciprocal of 18, which is the required focus. Nothing could be simpler than this calculation, from which we have, to avoid complicated calculations, left out all considerations as to the distance between the two lenses, which in any case would only make a small fractional difference entirely negligible for such approximate foci as only need be considered. As to how the addition is to be applied each user will be a law to himself. We have seen a well-blackened pill-box with the supplementary attached to the bottom of the box, which had previously been cut out so as just to leave an annulus of cardboard sufficient to secure the glass to. (It would be possible to find a box which just fitted the lens; care should then be taken to see that the lens was put in square—that is to say, not tipped to an angle.) This pill-box could be used as a cap, or it might be of such size as to go inside the lens tube.

We have seen a studio portrait lens fitted with a supplementary for use in copying pictures. It often happens that some old faded "carte" or glass picture is brought to be copied to a certain size just beyond the camera extension's possibilities. A sixpenny lens will do all that is needed; it will make the field more curved, and limit its diameter;

but for the case in point this would be immaterial, as "stopping down" would bring about any needed amount of sharpness over the whole field, and would only entail a few added seconds of exposure. We have seen the plan carried out by the use of an old pasteboard plate-box. A piece first covered over with dead-black paper was cut out to fit closely in the lens-hood, and was kept in situ by another piece of the box bent to the shape of the hood, placed inside it to press the disc home. The disc was pierced in the centre with an aperture just smaller than the supplementary lens, which was pasted with stamp paper over it. In another instance a more elaborate arrangement was made use of. The lens, instead of being pasted in position, was slipped into grooves made of cardboard glued to the disc, a further strip being glued to prevent the lens dropping through the grooves. This arrangement was devised to enable a series of supplementary lenses to be employed.

We think we have now given sufficiently practical explanations to enable any one to see the advantage of, and to use in his practice, any necessary or desired lens as a "supplementary."

HAND CAMERA FAILURES.

At least once a year, and usually during that period technically known as the "silly season," publicity is given to the exploits of some enterprising possessor of a hand camera who is reported as having succeeded in obtaining a dozen "perfect" negatives from twelve consecutive exposures. It is true, corroborative evidence is seldom forthcoming, but this is a matter of little importance, seeing that those who pursue the science of photography, like those who practice the gentle art of angling, are proverbially above suspicion with respect to veracity. In any event, these interesting "takes" are altogether exceptional, inasmuch as the experience of our highest authorities agrees with that of the average amateur as to the frequency of failure that follows the use of the hand camera, in comparison, that is, with the number of successes which result when employing one supported on a stand. Writing on this subject, and referring only to advanced workers, Mr. Welford, in his well-known book, declares that "the majority of good results obtained are quite disproportionate to the number of hand cameras in use." How many good hand camera workers are there? Not many, I fear. To put it plainly, the purchaser of a hand camera does not, as a rule, succeed in pleasing either himself or anybody else.

If the foregoing expert opinion be true when applied to experts, we cannot be surprised if the amount of success achieved by the ordinary amateur be small indeed. And yet, in spite of this, it is instructive to note that hand cameras have literally rushed to the forefront in public favour, and, so far as numbers go, stand at the present time without a serious rival. And remembering this, and knowing that during each season, if the weather Fates be propitious, tens of thousands of enthusiastic men and women (not to mention boys and girls innumerable) devote a great deal of time, attention, and money to the practice of hand camera photography, it is passing strange that the causes operating against better success have not hitherto been more systematically studied. So far, indeed, this vitally important aspect of practical and popular photography has been largely ignored by our leaders in the Press and in our societies, who have preferred to centre their energies chiefly on the elucidation of the various problems affecting printing and development.

In the limits at my disposal it is, of course, quite impossible to go at all fully into the causes of, much less into the appropriate remedies for, hand camera failures. Instead of attempting this, I propose to refer only to the principal

points calling most urgently for inquiry, with the hope that general attention may be drawn to the subject, and that hand camera users will do what is possible to bring about a more satisfactory state of things in this direction than at present exists. In the first place, let us note what are the chief causes of failure. These may for convenience be divided into two categories, namely, those that are personal and depend upon the attributes of the individual, and those that owe their origin to defects in the instruments used.

1. Personal Causes.—The causes of failure inherent in the user of a hand camera may be summed up in a few words, although they are none the less of the highest importance, by saying that no one can hope ever to rise above the merest mediocrity who does not possess the "photographic faculty." The science of photography in each and all its branches can, of course, be acquired by diligent attention to the necessary instruction, but knowledge of the science without possession of the art of photography will not enable its possessor to produce sun pictures which shall be aught else save crude and wholly inadequate reproductions of the form of things. And if the "photographic faculty" be essential to the making of an artist who does his work by means of a stand camera, it is tenfold more requisite, because it has to be specialised to a high degree, for one who uses the far more complex and difficult hand camera apparatus. In the use of the latter, and in addition to the general requisites for producing satisfactory results, no one can ever succeed who is unable to take in the situation and perform the necessary manipulations, not only correctly, but with the maximum of speed. Indeed, to be able to *see* and to *make* a picture, as well as to *take* it without delay and without excitement, constitute the real and salient difficulty in the vast majority of hand camera subjects. To do this, you suppose the possession of mental and physical qualities in an individual that are not only essential, but are extremely rarely found. In a word, a good hand camera worker must be a scientific expert, a trained observer, and a thorough artist, in addition to which he must be able, as it were, to bring into action his characteristic qualities at the exact moment when their presence is required, and that too often with but an instant's warning. His faculties, like his lens, usually have to be focussed rapidly on moving or evanescent objects, and his decisions, like his exposures, have to be made at express speed.

2. Causes Dependent on Defective Apparatus.—At the outset of this second section, it must be admitted that the hand-camera worker is terribly handicapped owing to the extraordinarily inefficient and unskilful manner in which his apparatus is constructed. For not only is there no single hand-camera, as a whole, on the market that in itself represents the present high-water mark of our mechanical and optical knowledge, but practically every component portion is marked by some constructive defect which greatly militates against the production of good results.

In view of the great advance towards efficiency effected in recent years in almost all other industries, it is difficult to account for this lack of enterprise amongst the manufacturers of photographic apparatus, though, doubtless, the characteristic conservatism of our race, and the immense importation of photographic goods from abroad, of the cheap and nasty variety, have much to answer for. But, leaving this general indictment, let us briefly examine some of the more important parts composing a hand-camera with a view to discovering how and when defects in them hinder or prevent success.

Shutters.—During the past five years the output of various types of shutters, differing in make only in some slight degree, has been perfectly enormous. And yet it must be confessed that no reliable or appropriate pattern for hand-cameras has yet been devised. A very large percentage of those now in use are of foreign construction; they are unreliable with respect to speed rates, are unscientific as regards proportional lighting

values, are for the most part unreasonably expensive, and are exceedingly liable to get out of order. Of British-made forms very few are practical, because, though admirably suited to stand-cameras, they are not adequate to the needs of hand ones. To be efficient, a shutter for this latter instrument must be light, compact, and durable; its release must be effected by the slightest pressure, and that too without noise or vibration; its speeds must be regulated with mathematical exactitude, and, most important of all, it must be so constructed that the amount of actinic illumination of the sensitive film is in inverse proportion to that of the object to be photographed, in the manner that light is admitted by "foreground shutters. Indeed, it is a matter of perennial astonishment to expert photographers that the principles upon which a scientific shutter for hand cameras ought obviously to be constructed have been, and still are, so persistently ignored or neglected by all our home and foreign manufacturers. One practical result of this lamentable condition of inefficiency is that it is very seldom that an untouched print from an untouched negative of a land or seascape can be regarded otherwise than as a failure.

CHANGING APPLIANCES.

With respect to the various methods adopted for plate changing, it is stating but the barest fact to say that none yet devised is practical, durable, and always to be relied on. In the case of so-called "automatic" changers they frequently jam or otherwise refuse to work, or work so inaccurately that they have earned universal condemnation. In bag-magazines, which are fitted with a lifting arrangement, successful working is by no means invariably the rule. For some occult reason the only really reliable form of this contrivance, in which the front plate projects slightly above the rest and is easily and with certainty grasped by the fingers and moved to the back, has never come into general use. The favourite and highly inefficient method is to lift, or to attempt to lift, the back plate to the front by means of a fragile metal arm. Against this arrangement the objections are many and important, and its perpetuation is a very common cause of spoilt plates, chiefly through double exposure.

Of double backs, whether of the "book" form, or of the even more erroneously named "solid" variety, as of roll holders for films, it is unnecessary to speak. Their constructional sins are calculated to make the most delicately nurtured amateur user of language of a highly reprehensible character.

FOCUSSEING SCALES AND DIAPHRAGM STOPS.

That neither of these is seldom otherwise than incorrectly marked is but another instance of remediable inefficiency, and very fruitful sources of hand camera failure.

VIEW FINDERS.

When we consider that a very large proportion of pictures attempted to be taken by means of a hand camera can only be glanced at, and their limitations determined during the few seconds they are visible in the finder, and when we remember that this latter appliance is usually but a fraction of an inch in its longest diameter, and, further, when we note that the view seen in the finder and that cast on the plate are not identical, and, moreover, that the alteration in the nature of the picture caused by the use of the rising front is seldom shown, then it cannot be a matter for surprise that the construction of the ordinary finder is answerable for whole lists of failures.

LENSES.

With the making of modern lenses there is less legitimate reason to complain than with any other portion of the camera fittings, inasmuch as this is the one department of photographic manufacture that has steadily and ever rapidly progressed. A really good lens is an expensive luxury, and that it is still to expensive recent developments in the trade clearly indicate

With the cheaper makes of camera the far less efficient varieties of lenses are for the most part fitted, and of these a large proportion is imported from abroad, without even the guarantee of a maker's name. But where inefficiency most generally comes in is in the case of those lenses, of both British and foreign make, which can only be worked with a small aperture. Were the normal average light prevailing in these islands far more actinic than in reality it is, doubtless the usual aperture of $f/8$ or $f/11$ would amply suffice for ordinary purposes. Unfortunately, however, we have to deal with atmospheric conditions as they actually are, not as they used to prevail in the summers of long ago, and that being so, a hand camera which is fitted with a lens having a working width no larger than those just specified is quite inadequate if it is to be used otherwise than during those few bright weeks when the sunshine is at its best. So, also, much of the advice given in our text books and by our other authorities concerning the use of small stops is based upon the experience obtained either during the summer holidays at the seaside, or upon the remembrance of the old-fashioned summer days. Some even go further, and counsel the use of slow plates. Should the much-harassed amateur follow this advice, as perforce he often must, he is at once doomed to spoil probably the majority of the plates he exposes. As a matter of simple fact, about which there can be no question, the hand camera ought to be available throughout the whole year whenever there is a reasonably good actinic condition of the atmosphere, and would be so were lenses always employed having a maximum working aperture of $f/6$, and, moreover, were fast rather than slow plates invariably used.

GENERAL STRUCTURAL DEFECTS.

The wood used for the manufacture of most hand cameras being seldom thoroughly seasoned, properly selected, and skillfully put together, it is liable not only to warp, but also to break under slight provocation. Neither is it common to find waterproof glue is used for joining the wood or for affixing the bellows or the covering leather. For one or other of these reasons we owe the readiness with which magazines and double backs admit light and dust to their contents, and both light and dust are certain and frequent spoilers of negatives. Doubtless in time manufacturers will use only the best and most appropriate kinds of wood, or will employ as a substitute one or other of the extremely hard, light, and easily workable amalgams of aluminium which are now so largely used in other industries. Another, and a wholly remediable, source of dust, and therefore of failure, is often created by making the base-board in folding cameras slightly too small, with the result that a crevice is left along its edge when the instrument is closed. This not only admits dust freely to the surface of the bellows and other external parts, and from it to the interior, but also allows it to settle on the lens surface, thus leading to diminished rapidity, and consequently to lessening the chance of successful exposure. But it is quite needless to go more fully into the question of general constructional defects, inasmuch as it is obvious that, for the many, hand cameras are made to sell rather than to work and to last. Where we as a nation specially fall off in the making of hand cameras, as in many other goods, is in what is called "finish." And in this matter, if in no other, we might with advantage copy the methods usually prevailing in the United States, where "finish" has been brought to a pitch of perfection seldom seen elsewhere.

Such in briefest outline are some of the causes of hand-camera failure. As was shown, failure may be, and often is, due entirely to lack of knowledge, or the absence of the proper temperament on the part of the user of the instrument. It is, however, far oftener due, either directly or indirectly, to bad or inappropriate construction of the camera itself. During

late years there has been a general overhaul of our trade and business methods with a view to bring them abreast with the needs and the wants of the times in which we live, rather than to keep them in correspondence with those of our forefathers. Adverse and advisory criticisms have been many and loud, and the fierce light of publicity has been turned on dark corners innumerable, with the result that in many directions reforms of prime importance have been effected. But so far very little improvement has taken place in the manufacture of photographic materials, and the only strikingly loud voice that has been raised is that of the advertiser shouting the unmerited praises of his wares, and proclaiming each and all to be the "best" and the "most reliable." The fact, however, remains that in photographic materials, as in so many other matters, the purchasing public still demand the best, and that best cannot now be procured from our home markets, which are in an annually increasing ratio being flooded with duty-free goods of foreign manufacture. If in the near future we are to stem this highly undesirable invasion, and secure our lost trade, it is certain that our manufacturers must adopt more scientific and modern modes of production, must bring themselves into touch with the needs of their customers, and must, in a word, keep the banner of efficiency flying, and make it the hall mark of their wares. The world moves continually forward, and either we must move with it, or, if we neglect to do so, we most certainly will find ourselves, where many of our present patterns of hand cameras ought to be, on the national scrap heap.

F. GRENFELL BAKER.

THE OBJECTS OF A PHOTOGRAPHIC SOCIETY.

[Presidential Address to the Edinburgh Photographic Society.]

IN delivering inaugural addresses it is a common practice to make a survey of the present state of affairs and of the possible lines of advance, and in speaking to you on the present occasion I propose to do something of the kind, as being valuable in realising what our objects are, and as suggesting the directions in which we may usefully employ our energies.

With regard to the second point, especially in connection with our Society, it is essential to advance. A society cannot stand still; it can only slip back or step forward. And here I would like to call attention to the fact that the activity and usefulness of the Edinburgh Photographic Society is not to be measured by its mere numerical strength, or even by the prosperity of its treasury, though both these are good indications, but is rather to be judged by the amount of active work that its members carry out, not merely in photographing, but rather in developing photography, both from the scientific and artistic point of view. Better a dozen earnest workers meeting to discuss their struggles to push on than a society of five hundred whose ideal is the "snapshooting" of their friends, views, buildings, and the like, and who are content to meet as a society to hear a lecture on some subject more or less photographic, and then forget all about it. I do not think, however, that our Society is represented by either of these two imaginary bodies; it comes rather in between, and the more I can encourage the spirit of the former, which I am glad to say I believe animates most of its members already, and drive away the unenterprising attitude of the latter, the less I shall feel I have failed in my presidential duties.

The question then arises: How are we best to attain the desired end of carrying out our duties as a Society? which I consider consist, firstly, in putting our beginners in the right way and providing our more advanced workers with the materials and appliances not usually available to private individuals; and secondly, and of much more importance, the bringing of new ideas before each other, and by discussion and consideration weeding out the good from the bad, and fashioning them so as to be useful. This twofold aim, however, requires no little

sacrifice, which one and all must be prepared to make. We must be ready to find money, for I imagine that there is no one that considers that either our equipment or premises are satisfactory; but, what is more, we must be prepared to give more thought perhaps rather than time to the pursuit which is the occasion of our existence.

How the money is to be raised is a delicate question. Let me, however, make one suggestion. Would it not be better to rely on the sturdy self-sacrifice that has so nobly marked the Scottish character in the past, and provide it from within rather than look for it to drop from the hands of some princely benefactor without? If we do not work for it we shall in all probability neither value it nor benefit by it.

Leaving this matter in the hands of the Society—for in a democracy like ours it is for them to speak rather than the President or Council—let us now consider the directions in which we may profitably spend our efforts, and though perhaps none of my suggestions may be in any way new, they may lead some present into lines of work that may be fruitful.

For this purpose I shall look on photography from three aspects:—(1) As a means of simple representation; (2) as a vehicle for pictorial expression; and (3) as a field for scientific research; though I am aware that all three sections overlap to a very large extent.

As a means of representation, photography has its most common and obvious application, and I need only refer to its employment in portraiture, photo-micrography, star-mapping, and the like to show in what diverse directions it is utilised. For those who are contented to apply photography only as a means of representation I would suggest that they should concentrate their efforts as far as possible in some particular direction, and in this way there is much that is valuable to be done. Systematised survey work of an ever-changing town, as is now being carried out by our own Society in so satisfactory a manner, as the current "Transactions" point out and the forthcoming Exhibition will demonstrate, the study of a river from source to mouth, as suggested by Mr. Dibdin; the study of the agricultural peculiarities of a district; the following up of a style of architecture; the recording of meteorological or other natural phenomena, etc., are merely examples of the directions in which photography, as a representing art, can be made the basis of the means of preservation of, and of the addition to, much valuable knowledge. As to the means of representation, and in how far the representation is exact, is rather a question for the third or theoretical aspect of the subject, rather than the present; but I may add that beyond the simple photograph attempts may be made to represent the solidity of the object by stereo-photography, its colour by the various processes of colour photography, and its movement by the cinematograph, and in all these directions there is much that may be done; e.g., taking the use of the latter instrument alone, there are many manual operations being replaced by mechanical, so that their methods will be forgotten, and can only be adequately represented to future generations in such away; or, taking another case, as I saw recently exhibited in Cambridge, the gradual growth and motion of plants may be recorded, and can be exhibited in more rapid and convenient sequence than occurs in nature.

As regards photography as a means of pictorial expression, I will say but little, as I feel that there are those present who are much more capable than I of discussing the matter. However that may be, I think there can be no question in the mind of the dispassionate critic who is in any way acquainted with what is being done, that photography may be employed as a vehicle for the expression of an artist's ideas just as a brush, pen, or pencil, and with the exception of its being practically confined to monochrome, with almost as little restriction. The public, however, require education; there are many who still think that the essential feature of a photograph is that it should be what they call "clear," and here, I think, it is our positive

duty as a Society to hold our exhibition in a hall of greater suitability and accessibility than our present room, so that the "man in the street" may have a better chance of realising what good photographic pictorial work is like.

Coming to the third, and to me the most interesting, division of the subject—viz., the theoretical, I feel that there is so much that should be said that it is difficult to say anything without being brought to book for being one-sided and partial, whilst of what I might say there is not a little that is but imperfectly known and disputed that I run the risk of setting up a discussion beset with so many thorny points as to permanently endanger the peace of mind of the Society rather than stimulate its activity.

To the beginner studying scientific photography it seems an easy enough affair—some apparently straightforward optics and simple chemical reactions; but on a little further investigation, the difficulties in photography, as indeed in every other science, become apparent, and it is obvious how little has been done, and how much has to be accomplished before a thorough knowledge of what really happens every time "you press the button and we do the rest" occurs. How few care or think about it at all, but are simply content to accept the result?

To raise a few points, I should like to ask, in the first place, in how far are our photographic representations misrepresentations? Much has been done in perfecting plates and lenses to give the correct value of natural colours in monochrome, and a form and proportion of our print exactly depicting the objects photographed, but in how far do they really do it? For example, is the strictly rectilinear, sharply-focussed architectural photograph that is taken of a building at close quarters with the best lens and carefully-levelled camera really like the mosaic we build up in our minds of the numerous images formed by moving out very narrow-angle eyes, and do not what some people are pleased to call the "fuzzy-graphs" of certain pictorial workers give a truer picture? I am by no means sure. Looking in another direction, if we try and analyse the chemical and physical actions going on in even our simplest processes, we are in many cases face to face with similar difficulties, whilst in the fundamental process of all, though we may talk fluently about latent images, sub-haloids, and the like, how much is but purely speculation!

However, the position is far from hopeless; earnest workers in all directions are piecing the various puzzles together, and I feel sure that all can lend a helping hand. Shall not members of our Society now, as in the past, place a few fragments in position?

Besides the fundamental problems, there are many side issues, and amongst these I would first mention colour photography. Much has been done in this field, but I feel that in spite of the extraordinary ingenuity that has been expended in devising processes, that the main efforts now being made can only result in compromises that are more of interest as scientific curiosities than of real value from the point of view of perfect accuracy of representation or pictorial work. However, it may be that one of the many processes of colour photography so freely heralded by the daily papers, may turn out to be all that can be required. In this connection I may mention that no little progress has been made by Professor R. W. Wood in perfecting his diffraction process, which he has also adapted to the Joly method, thus substituting invariable diffraction colours for the fugitive aniline dyes previously employed. But though the results exhibited at the British Association were beautiful, the application is cumbersome, and far removed from the ideal colour photograph some people hope some day to be able to hold in their hands.

Another line of work that I would like to suggest to our workers is the study of the photographic action of what one may call invisible light, and of chemical reagents. For instance, X-rays produced under different conditions are differently active, and

again from radium rays in their photographic effect. Dr. Russell showed some years ago that the photographic action of printed paper, metals, etc., was due to hydrogen peroxide. Does this compound play any part in the other cases when an image is produced on a plate?

Finally, have we reached perfection in our processes or manipulative skill? I think not, and I feel that much might still be done by working in an intelligent way, as some are doing, to render the practice of photography more simple, and its results more permanent and beautiful.

In conclusion, if I may have stimulated any of our members to start work in one or other of the many directions I have indicated, or have encouraged others to persevere in the studies they are already engaged in, I feel that I have spoken in vain, and that when another session commences I shall be able to record not only that the Society has stepped forward in every direction, but also that, what is, after all, our object, the Science and Art we love so well shall have been advanced by some of our efforts.

J. TUDOR CUNDALL, B.Sc.

NOTES AND QUERIES.

By THE AMATEUR OPTICIAN.

What is a fair charge to make for a small set of negatives required for picture post-cards? I was asked a few weeks ago to take ten negatives of various parts of the City, and the price offered was the munificent (*sic*) sum of 3s. 6d. each, this being less than the value I set upon my time and qualifications. The offer was declined with thanks. The commission was eventually taken by an amateur, and executed satisfactorily, though at some cost in time and material. I think, on the whole, a photographer may be fairly termed "expert" whose percentage of failures averages no more than one in twelve; and certainly a man who can go round a district and take a set of negatives of good quality, and without undue loss in time and material, deserves to have his labours more amply remunerated.

Some time ago a request came in for a price for a set of twenty stereoscopic prints and the same number of stereo-transparencies; there were twenty negatives to be taken within a radius of, say, forty miles. The pictures were wanted by a successful Colonist and resident in New Zealand, who wanted these as mementoes of his early life and environment. Now, I ask, what is a fair price for such work—twenty negatives, and the same number of good prints and transparencies? After making a rough estimate I concluded that twenty shillings per set would pay me, and quoted that amount. I heard subsequently that the successful Colonist had abandoned the idea of having them made; probably other quotations had been received, and all had to be, from the buyer's point of view, too costly. If the Professional Photographers' Association has not fully considered the matter, I believe a schedule of charges for various actual and hypothetical commissions would be of value to the trade and profession generally. I do not think there would be much in the way of "cutting" either by professionals or amateurs, a fair estimate being understood. The average amateur, if capable, is, in my experience, a person who has a fair notion of prices; he does not often under-estimate the value of his work.

I had a curious, and not very agreeable, experience some years ago. I was doing a certain class of work in an important centre, and a very great friend was similarly engaged in a town about ten miles away, the work being all kinds of outdoor and indoor photography in the shipyards and engineering establishments. A rather particular piece of work was to be done—one of those awkward jobs where there is a wide space to be covered, and a difficulty in getting a point of sight; as a fact, I believe the only wide-angle lens in the district capable of doing the trick

was in my outfit. Well, I quoted my usual price of 31s. 6d. for a 15 by 12 and proof, and got no reply. A week or two after my friend turned up to consult me as to the best method of taking this particular photograph, and to borrow my camera and lens—the lens! His estimate was 50s., so that, apart from the intrinsic value of one's work, there is a danger in *under-quoting*. I felt a bit sore at first, but my friend was a splendid fellow and first-rate operator—now, alas! gone to his account—but the feeling soon passed off, for, after all, the work could not have been in better hands. Many times in the past twenty years I have been puzzled as to a fair and reasonable charge, and have often wished for a "standard" rate; the difficulty has not been a personal one entirely, because the matter has been discussed with professionals in a variety of districts with the same result—viz., no uniform rate.

No matter what may be the grounds, real or imaginary, the penny-a-liner always scores over every rumour relative to the discovery of photography in natural colours. From the scientific point of view, natural-colour photography as an accomplished fact would be a grand achievement; but, pictorially, I cannot see that it would be so satisfactory as many people would have us believe. Take our public streets and buildings, for instance; is it not clear that, speaking generally, these are best treated and most leniently dealt with when reproduced photographically in modest subdued and "subfusc" hues. Every town and city contains, unfortunately, some philistine, not to say barbarous, property owner whose taste in the matter of colour and decoration never reaches above the level of yellow paint. What about the dirt and squalor? We can at the present decently represent all this in black and white, or monochrome, which is something to be thankful for. Just think, too, what a change there will be in our studios! I strongly recommend the P.P.A. not to entirely overlook the matter, and to add certain queries to their recently published schedule referring to the "Operators' and Assistants'" certificate, e.g.:—

Has he a fine artistic eye for the arrangement of colours?

Can he apply "grease paint" and make up well?

Is he able to distinguish between a "mole" and a "pimple," and what notion has he of treating these scientifically, and obliterating an undue preponderance of freckles?

And so on. We must be prepared for all these contingencies.

THE TESTING OF ORTHOCHROMATIC PLATES.

II.

I PROPOSE now to attack the spectrogram, and to prove to you, if possible, that it can be totally misleading.

In the first place, you must recognise that there are two distinct types of spectroscopes—the one in which light is split up by a series of prisms, and the other in which a diffraction grating is used. Whichever you elect as correct can be proved wrong, and, if you admit both right within their limits, both can be proved to be wrong.

Dealing first with the prismatic spectrum, a totally erroneous reading may be made, because the more refrangible rays, the yellow, orange, and red, are so humped together that the density obtained in these regions is misleading. The diffraction grating, on the other hand, spreads these rays out normally, so that faint action may be overlooked. It is, of course, easy to translate the one into the other, for it is well known that the intensity of the colours is inversely proportional to the space they occupy.

Freiherr von Hübl has given a very instructive diagram of the prismatic and diffraction spectroscopic curves, which I now show, and he says in his work, "Theory and Practice of Three-colour Printing," an English translation of which has just been published by Messrs. Penrose: "We obtain with a

diffraction grating a correct statement as to the colour sensitiveness of a plate, but such spectra are of poor luminosity, and the minor action of the less refrangible rays, which are the most interesting to us, may be completely overlooked.

"If we expose, for instance, the red sensitive plate of commerce to the diffraction spectrum, we miss the red sensitiveness entirely, leading us almost to believe that the plate is not orthochromatised, and still this plate may, if light filters are used and sufficiently long exposures are given, render red pigments sufficiently light.

"For this reason, it is better to employ the prismatic spectrum, and to correct the results for the normal spectrum.

"To obtain accurate results, we must further measure the densities of the band on different plates, and the Martens

Fig. 1.

polarisation photometer of the firm of Schmidt and Haensch as a very convenient instrument for this purpose.

"How very different are the results if the prismatic or the diffraction spectrum is used we shall demonstrate in a few examples.

"Curve A represents a gelatine plate sensitised with erythrosine. According to the prismatic spectrum, we expect the same sensitiveness for yellow, green, and blue, whereas the normal spectrum shows a curve of very limited sensitiveness for yellow-green rays.

"Curve B shows a gelatine plate of apparent greater red sensitiveness if exposed to the prismatic spectrum. The normal spectrum shows a very small sensitiveness for red, and this plate, if used without a filter, on a coloured original will actually exhibit no red sensitiveness.

"The eosine silver collodion plate, C, if judged by the results obtained with the prismatic spectrum, shows only sensitiveness for yellow-green, whereas this plate does not render yellow-green pigments lighter than the blue, which corresponds to its behaviour towards the normal spectrum.

"A plate, D, showing in the prismatic spectrum equal sensitiveness for all rays, would be, according to the curve of the normal spectrum so little sensitive for the less refrangible rays that red objects would be rendered black.

"If all equally pure and saturated colours are to be rendered equally light, the normal spectrum must correspond to a curve which is practically a straight line. In the prismatic spectrum the plates would have to show a sensitiveness represented in Curve E."

I have stated that, whichever spectrogram you elected to consider as correct, I would prove that it was wrong, and I would particularly commend a careful consideration of the above extract from Freiherr von Hübl; and I would also, in this connection, requote the concluding sentence of Mr. Dyer's remarks: "Nature's colours are apparently not so spectroscopically pure."

It is an axiom that all objects illuminated by white light reflect their own particular colour plus white light; the spectrum is composed of pure colours only, therefore I argue that you cannot judge from the action of pure colours the action of impure. Some of you are probably acquainted with chemistry, and I would ask you whether it would be fair to estimate from the action of an absolutely pure chemical the action of an impure sample. To bring this closer home to all here, I would ask, Is it fair to judge of the developing action of an old pyro solution that is absolutely black by oxidation from the action of a freshly-prepared solution?

Because, then, in nature all objects illuminated by white light reflect white light, should we condemn the use of a chart, a group of flowers, or a landscape as a test for an ortho plate? Surely, for "the man in the street"—the man who buys plate to expose in the camera and not in the spectroscope—a chart is a better test if he is going to copy pictures, a group of flowers is a better test if he is to copy flowers, and a landscape is a better test if he is going to do general outdoor work—better in all cases, because the tests approximate the more nearly to the conditions of every-day work.

I agree with Mr. Dyer that we are led to expect a great deal too much from spectrographic tests, and but little difference is to be seen without the use of a yellow filter.

And why do we see such slight differences?

If we examine this subject a little more closely, and put into tabular form what little we do know, we may arrive at a clearer understanding. The following table is drawn up from various published estimations by Abney, Eder, and others, and, while I do not give the actual dates of the papers from whence the table is calculated, you will, I hope, accept my word that I have put no lead in the scale, and it represents, so far as I can gather, a correct statement.

In the first column is the colour, and, to define it more correctly, is the Fraunhofer line marked by a letter and the usual sign λ (lambda), meaning wave length; in the second is the visual luminosity of these colours, marked V.L.; in the third is the sensitiveness of the plate—that is, the ordinary plate luminosity—marked P.L.; in the fourth column is the orthochromatic plate sensitiveness or luminosity, marked I.P.L.

I have further divided this table and added the luminosity together, so that one part should approximately represent the sensitiveness of the ordinary, and the other the ortho sensitiveness, and a slight examination will show why a chart or other natural object is unsatisfactory when compared to our notion preconceived from the spectrogram.

Colour.		V.L.	P.L.	I.P.L.
Orange	λ C	10	0	0
Yellow	λ D	80	0	10
Yellow-Green	λ D $\frac{1}{2}$ E	100	0.1	40
Green	λ E	30	0.5	10
Blue	λ F	10	80	30
Blue-Violet	λ G	5	100	100
Violet	λ H	1	80	80

Now, it is obvious from this that, if we consider that the numbers represent chemical action or density, although we have increased the iso plate luminosity for the less refrangible rays, yet the blue and violet sensitiveness remains constant, and, unless we use a yellow filter to cut this down, the result must be unsatisfactory.

There is one point in this last paragraph which leads me to another subject. I stated that the blue and violet sensitiveness remained constant. I would guard myself against possible attack by stating that this is not a necessity of ortho plate-making. The manufacturer can, and does in some cases, n

only isochromatise his plate, but reduce his blue sensitiveness by introducing an excess of dye, or purposely adding a colour inert dye so as to stain the gelatine, which will naturally, to some extent, obviate the use of the yellow screen. Hence we get statements that certain plates can be used without a screen. This is perfectly true of every iso plate; whether, however, the ideal result is attainable by these means is another question altogether.

The ideal method would be to keep the blue sensitiveness constant and increase the speed for the ortho half of the spectrum. The result would be, if we take the visual luminosity as a guide, a blue sensitiveness of 1, and a yellow sensitiveness of practically 15, which means that a plate would have an H. and D. speed of 300 for blue, and 4,500 for yellow.

I dream sometimes, both in and out of bed, but in my wildest dreams I have never attained this height of plate manufacture, though, of course, it may come.

Summing up, it seems to me that the greatest cause of error lies in the fact that too many do not recognise that the spectrum is absolutely pure light, and that no other object gives us this—that every natural object or pigment reflects, not only its own particular colour, but also white light when it is illuminated by white light.

Further, the importance of the character of the illuminant has not yet been taken into account by the average worker, for it is a fact, and a well known fact—at least, so well known on the Continent, at any rate, that the illuminant plays no inconsiderable part in the correct rendering of colours, that some of the best reproductive studios there have a revolving platform, so that the pictures or other subject can be revolved so as to be illuminated by direct sunlight, which is, of course, the richest in all colours.

It seems to me to be absurd for the maker of an ortho plate to object to the use of a chart on the plea that it reflects white light, because it must always reflect white light, and has not the intelligence to suppress this reflection for the ordinary and extra for the ortho; and, therefore, if the ortho plate is colour sensitive, the white light reflected from the chart must merely add to the effect of the coloured light. It certainly cannot extinguish or reduce the photographic effect, and therefore, if our blues are correctly rendered—or, rather, rendered alike in both cases—and the greens and yellows show but little difference, it is, I think, but fair to argue that the ortho sensitiveness of the plate is low compared to the blue, or the luminosity of the pigments or natural objects is low.

E. J. WALL, F.R.P.S.

DITCH-WATER PHOTOGRAPHY.

DITCH-WATER has long been a synonym for all that is dull and uninteresting, but even ditch-water has its charms, and it has proved particularly attractive to naturalists. One of these, Mr. Martin Duncan, makes a practice of fishing in dirty waters, much to the disgust, apparently, of some of his neighbours, who when they see him emerging from his residence with landing-net and bottles come to the conclusion that he is after sticklebacks. This confession he made as an introduction to his lecture to the members of the Camera Club recently—a lecture which bore the title "Ditch-water Photography." And the pastime has its sorrows as well as its joys. The fisher may feel huge delight at the unexpected capture of some rare organism with a long name, and he may always feel gratification at the acquirement of increased knowledge. But it is not all gay, this dabbling in muddy depths. On one occasion Mr. Duncan had to swarm up a tree for refuge from a herd of cattle which charged down on him, and had to witness the terrible tragedy of his precious camera being tossed into the water. Another time a rollicking he-goat caught him unawares, and sent him head over heels among the lowly inhabitants of the pond over which he was at the moment stretching to secure a prize. The catcher was caught himself by the agency of that jocular billy-goat.

Mr. Duncan always carries a camera with him when upon one of these piscatorial excursions. We say piscatorial, because it seems to be the right word to apply to an occupation which needs a net and a rod, but the beasties caught are not to be numbered among the pisces. Nor are they insects. Some of them, indeed, seem to be like animals with regard to movement, and to belong to the vegetable world in other respects. However, we are quite safe in taking refuge behind the convenient term organisms.

The naturalist does not hunt these creatures from any impulse of the sporting instinct, nor does he want them for food. He requires them as specimens, and either preserves them as such, so far as they are capable of being preserved, or he nurses them up, feeds them, and watches their progress through his microscope. This is what Mr. Duncan does, and by means of the microscope he has made a number of new observations, while with the assistance of his camera he has taken photographs of the greatly magnified objects so that others can take advantage of his labours. These photographs illustrated his discourse the other night, and very wonderful some of them were. Let us cite one case in which a careful study of the habits of one of these lowly organisms has proved of incalculable benefit to mankind, and as the case is a comparatively recent one it is all the more likely to appeal to the sympathies of our readers.

It is now a matter of common knowledge that the disease known as malaria, which slayed its thousands annually, and rendered large portions of tropical countries uninhabitable, is carried from victim to victim by the bite of a species of gnat—commonly called the mosquito. Now, the larva of the gnat lives below water in ponds, ditches, and marshy places generally. It is a curious-looking creature, somewhat like a small caterpillar, with a breathing apparatus near its tail, and it comes up to the surface of the water every now and then for a fresh supply of air. But if the water be treated with a little paraffin oil, so that a film spreads over the surface, the gnats' breathing arrangements are frustrated, and it soon dies for want of oxygen. So the remedy for getting rid of the mosquito is to dose the water where the larva is found with paraffin oil, and the creature is killed before it assumes the dangerous form. In this way a study, which unthinking persons might regard as puerile, has been of immense service to the world at large.

Another most interesting point in the lecture dealt with the photography of those much more minute organisms which come under the common term bacteria. These rod-like bodies are already familiar enough to most of us through the medium of photography, and they have an abiding interest, seeing that so many human diseases are traceable to their presence. But Mr. Duncan contends that the usual method by which bacteria are prepared for microscopic examination is all wrong, and he described how they were first subjected to heat and then treated with an aniline dye which was near the boiling point. "You might as well take a sheep," says he, "roast it, dip it in boiling dye, and then exhibit it as a correct likeness of the animal that browses on the hillsides." And to show the better way he exhibited a photograph of living bacteria. They were no longer like bits of black sealing-wax, but tubular bodies with aggregations of white protoplasm within the transparent membranous envelope. This was the first time such a photograph had been publicly exhibited, and it won deserved applause from those present. We regret that we cannot afford space for more than a mere résumé of a most interesting lecture.

THE first portfolio of photographs from works by old masters, published for use of members of the Arundel Club, is in preparation, and will be issued at latest by December 1. These photographs, which are to be of pictures and other works of art (often difficult of access) in private collections and elsewhere, of which in no case can reproductions be obtained in the ordinary course, will be issued only to the members of the Arundel Club. The present series consists of fifteen photographs in a neat case; but it is hoped that the club may be able to enlarge the scope of its activity to a considerable extent in the future, though this must, of course, depend on the amount of support received. The annual subscription is one guinea. Those who wish to join, or desire to receive further information as to the society's aims and methods, are invited to communicate with Mr. Robert Ross, 10, Sheffield Gardens, Kensington, W.

PHOTOGRAPHY AS APPLIED TO ARCHITECTURE.

A PAPER on this subject was read by Mr. E. Dockree before the Architectural Association last month. It was illustrated by a large series of admirable photographs of buildings hung on the walls of the meeting-room, and by nearly 170 lantern slides. In his introductory remarks the author disclaimed any intention of raising that wearisome and unprofitable controversy over the respective merits of sketching and photography as a means of depicting buildings. Architectural photography had its field. The late John Ruskin, no enthusiast concerning photography in general, said "it was the foremost means of translation or reproduction in a graphic form of architecture." By this utterance the great art critic did not exclude all other methods of depiction; his own exquisite drawings of architecture would at once dispel such a claim. But Ruskin recognised the supreme claim of the architectural photograph—its impersonality. A drawing, added the lecturer, must necessarily be tinged with the individuality and perception, or want of perception, of its author; in short, you do not receive an impression of the building through your own eyes, but through the eyes of the artist—nay, it is but an impression of his impression. Some medium is therefore required for affording an impersonal depiction of a building from which each beholder can draw his own deductions and impressions. Indeed, efforts are being made by some of the leading architects to obtain a revision of the Royal Academy rules with regard to architectural exhibits; a revision that would permit architects to show their work by means of photographs, geometrical drawings, and models, as well as or instead of perspective drawings, to which they are at present practically restricted.

Mr. Dockree went on to say:—"My claim for the photograph as the best means of exhibiting a building will doubtless be met by two objections:—(1) That the photographs can be 'faked.' (2) That buildings seen in photographs are frequently distorted, and are not truly represented. Both these objections must be admitted; in regard to the first I might rest contented to say, So can drawings. One has only to study perspectives at the Royal Academy for this fact to be self-evident. But if absolutely sharp, clear detail be insisted upon in a photograph, it will be exceedingly difficult, if not impossible, to fake it without detection. Only fuzziness to impressionism will disguise the effects of manipulation. And architectural photographs in general cannot be too sharp. In regard to the second objection, the fault lies entirely with the operator; if you see a distorted building or one in impossible perspective, blame not the science but the photographer.

"The most common causes of failure are: (1) The architect desires to get too much in one plate; he wants 'to look over his head' or 'round a corner'; in short, tries to achieve the impossible, in which amiable endeavour the photographer collaborates. Occasionally, for a special purpose, it may be necessary to take a somewhat distorted view; but in general the photographer should resist a request for such a view. (2) The operator receives instructions to do 'the best he can'; and with some operators the best does not amount to much. In this case the photographer goes blindly to work, never pointing out drawbacks or defects (from a photographic standpoint) in the views suggested or offering a workable alternative. A third reason is a want of knowledge on the part of the operator of either the science of optics or the laws of perspective, or both.

"Concerning size; the larger the photograph of an architectural subject can be made, the better in every respect; the details and the proportions of the structure are shown to a greater advantage. A small picture may be a gem of photography in its way, but you instinctively feel you would like to see it done larger. The resulting picture lacks that 'quality' and 'vim' only to be obtained by working direct. Again, small plates are 'small' in price and tend to carelessness and slipshod work; whereas a large plate and its after manipulations compel you to walk round and study your subject—consider every standpoint—the final one being selected only after mature deliberation.

"For architectural work artificial light should never be resorted to if it can be avoided. Though an interior may appear absolutely dark to the naked eye, there are always rays sufficient to act upon a sensitive plate if time be given. Prolonged exposures are not always possible, and one is frequently forced to employ some sort of artificial aid. Though I have never employed it, I believe acetylene gaslight is the best for photographic purposes, as the spectrum of

this light most closely approximates to that of the sun. I have invariably used electric arc lamps when photographing the auditoriums, of theatres and other dark interiors. One light I warn you not to use for architectural purposes, and that is the one most commonly resorted to—flashlight, magnesium. Its use results in a white glare over the objects nearest the camera, and the elimination of detail in the background, so that delicate under-cut carving looks as flat and formless as a stencil pattern on a wall.

"Unfailing patience and effort are required to obtain success in architectural photography. One must be prepared to work at it at all hours of the day and night. I have secured excellent negatives by exposing plates in the subdued light between 3 a.m. and 7 a.m.

"I would recommend nothing less than a whole plate or a 10 by 8, personally, I use a 12 by 10, and would a 15 by 12 if I could get about with it and all its appurtenances in a comfortable manner. The camera should possess double extension; that is, the 'front' and 'back' should be capable of being adjusted by means of a pinion and rack-work, the bellows slightly tapering; and the 'front' carrying the lens should have a 'rising movement' and, better still, a sliding movement in addition. All up-to-date cameras have a 'swing-back' capable of two movements, 'to' and 'from' the lens, and a 'reversing-back' to carry the dark slide, so that oblong and upright pictures can be obtained. Some workers find fault with the 'turntable'; they assert 'focussing' is a difficulty in a dark interior—what light there is coming up through the same from the ground or floor and detracting from the visibility of the image on the 'focussing screen.' The turntable has advantages over the solid base board; it reduces the weight of the camera, it facilitates your movements in finding the desired view, and gives rigidity to the whole apparatus, the latter a most important feature when working with lenses of long foci and in exposed positions. The tripod stand, or tripod used with the turntable, should be folding, with a sliding leg—two or threefold, if of the right weight, is immaterial. The camera and tripod when set up for use should not exceed 5 ft. 6 in. to 5 ft. 10 in. in height, thus being an average sight-line. A slow-moving spirit-level, circular in shape, should be fixed on the 'base-board' of the camera just at the side of the front. On the front itself, at the top of the side, a 'plumb index' should be placed, and another one on the side of the 'swing-back.' These three working together accurately place beyond dispute the absolute verticality of the resulting photograph.

"The next thing to be considered, and certainly the most important one concerning architecture, is the lens or lenses. One lens will not do everything required of it; and before deciding what to get I would strongly urge the enthusiast to consult some one well versed in the matter, and, if the pocket will allow, to purchase the best make possible. Then, should your results not be satisfactory, blame yourself and not the lens. Whatever make is selected, let it be a lens giving no wider angle than 65 deg. for an interior subject, whereas 60 deg to 65 deg. is a very pleasing range for exteriors of buildings. Lenses for architectural work must be of the rectilinear type and possess great covering power and marginal definition. Those of the genuine 'anastigmatic' series are absolutely the finest procurable for the purpose. Where the purse will allow, I strongly recommend the earnest worker to procure a 'battery' of lenses for his use. For instance, for a whole-plate camera a 6½ in., 9 in., and 12 in. focal lengths; for a 10 by 8 camera an 8 in., 11 in., and 14 in. focal lengths; and for a 12 by 10 camera a 10 in., 13 in., and 16 in. focal lengths. And to the last-named I would add an 8½ in. lens.

"The apparatus complete, the first operation after the selection of your view is the focussing. The screen upon which this is effected should be ruled into small squares, say, of an inch; this will facilitate the worker in composing his picture. In focussing, get your subject as sharp as you can—roughly so at first; see your vertical lines are vertical, and not, as one sometimes sees, converging to meet at some point. Your 'uprights' not being true, the camera must be generally 'levelled' and the 'swing-back' manipulated until the said lines are vertical, the levels all working true to each other; your picture should then be dead 'upright.' Now refocus, fixing upon some object midway between the camera and the middle of your subject. Note the appearance of the same at the top, bottom, and sides of your screen, using the lens stops to bring the whole view into general sharpness.

"The knowledge of the exposure to be given is only gained by experience; there is no fixed rule, subjects, light, and shade varying to an enormous degree. But bear this in mind: always give plenty—

after the shadows, the 'high lights' will look after themselves. After 'over-exposure' than 'under-exposure.'

Those plates having a medium rapidity will be found the most serviceable, satisfactory, and easy to work. Every plate used must be 'backed.' The difference in the resulting picture obtained from a backed and an unbacked plate is most marked; in fact, in some cases, especially where windows assert themselves in an interior, a backed plate is an absolute necessity, otherwise halation, the bugbear of photography, will be so evident as to quite mar the picture, though everything else is quite satisfactory.

A developer composed of pyro, in combination with potash or soda as the accelerator, is the best for the class of work under consideration. It yields, if properly adjusted in its components, a negative soft but vigorous, the class best suited for printing in either 'silver' or 'platinum.' In development the watch-words should be: 'Detail first, density afterwards,' not the reverse. To obtain the correct gradation keep your pyro down to a minimum, to start with; it can easily be increased as development proceeds.

A print to give the finest block for reproduction is the 'silver print.' By that I mean that done on one of the various P.O.P. papers and toned with gold. I prefer that 'toning' which includes 'sulphocyanide of ammonium'; the range of tones and the latitude of colour is excellent. The 'process worker'—by that I mean the 'block maker'—likes a good plucky 'blue-black' print full of 'vim' and 'contrast.' It yields a block far superior to any other class of print. In bad or dull weather one of the numerous 'gas-light papers' must be employed. For framing and keeping for show purposes there is no process equal to the 'carbon' or 'platinum,' but suitable negatives are required to give the finest results."

AN ANTITHESIS OF PHOTOGRAPHY.

When we see those clearly-defined charts of the heavens, showing gradations of stars that are invisible to the naked eye, and the various phases of nebulae depicted with truthful accuracy, we can form some idea what service photography renders to astronomy. Many recently-discovered planets have first been detected and their courses recorded on the photographic plate, and in other branches of science photography has given its aid in solving Nature's problems; and we may say, without fear of contradiction, that it has become the handmaid of science.

If we look at photography from another aspect, the business point of view, it seems to have taken a retrograde movement, and, however much we regret the fact, we must admit that it has somewhat lost its status, so to speak, as a profession, owing to the revolution that has taken place in its processes since the advent of dry plates. Its formulae are simple and its principles easily acquired, and small capital needed to set up in a small way accounts for the large number that have taken it up of late years and joined the professional ranks.

It has become an entirely universal hobby in every land, with amateurs in every class—of both sexes, too, we find. Are we surprised, then, that photographs have lost their charm, and fail to interest us when we see them scattered about—broadcast, as it were, good, bad, and indifferent? We become satiated and sickened of their ever-increasing abundance; it wears the faculty of appreciation, and tends to keep us apathetic, for familiarity makes millions of us all.

To hold our own it behoves us who are professionals now to make fresh efforts, and produce a better class of work than we have hitherto shown, that will appeal to the public and gain its sympathy. Technique alone will not lead to the goal of success; we must possess other qualities, a certain amount of art culture and individuality, that will raise our work above mediocrity and attain this end. "The education of the eye is the true foundation of all graphic arts, and without this we are only building on a foundation of sand." How, then, we to acquire this art culture, and where is it to be obtained? We have art schools in abundance open during the winter evenings, and the fees are quite nominal, or very small; but the benefits to be derived from these institutions are, as a rule, not appreciated by photographic assistants. They aim at reaching the goal of success by a royal road—a short cut, without preliminary toil and drudgery. In these schools we can learn the elements and canons of art, the principles of light and shade, gradation of tone, the laws governing

composition, true harmony of colour, and see the beauty of form depicted in those classic ideals shown there in casts and statuary. A knowledge of these principles is essential, and would prevent us making those errors that often mar our work. The more we think over the matter, the more we are convinced that art and photography should go hand in hand. The canons and fundamental principles pertaining to art apply equally to our profession. To do artistic and conscientious work we must possess a certain amount of art culture, and, lacking this quality, we shall find ourselves handicapped in the future, and it will take years for us to find out and correct those errors we have passed over unnoticed in the past. TRIPON.

THE CITY AND GUILDS EXAMINATION IN PHOTOGRAPHY.

The following is extracted from the report of the work of the department for the session 1903-4:—

PHOTOGRAPHY.—SECTION A.

In the Honours Grade, every candidate passed; but, on the other hand, only two did well enough to gain a first class, and only one obtained sufficient marks to qualify for a prize. In the Practical Examination the work done showed a distinct advance on previous years, but the specimen work sent in was not up to the standard of last year. Candidates should be advised to take more trouble over their specimen work.

Most of the papers left much to be desired as regards a satisfactory real understanding of the why and the wherefore of the various processes, and none of them gave any evidence of a satisfactory knowledge of photographic optics.

In the Ordinary Grade the percentage of failures is lower than in previous years, and as a rule a very fair all-round knowledge of processes was shown. Some candidates would have done better if they had more clearly grasped what is necessary in answering a question. For example, when one is asked to describe a process in the fullest possible detail, it is not sufficient to say "develop, fix, and wash in the usual way." Teachers should impress on candidates that examiners cannot be expected to assume that they know a thing unless their knowledge is actually set out in their answers. Furthermore, in several of the answers, writing "at large" took the place of a concise and exact description of the process referred to.

Not a single candidate gave a really satisfactory answer as to the effects of stops on the efficiency of lenses and it would seem that too little attention is still paid even to the most important parts of elementary photographic optics.

The least satisfactory feature in both grades is the small proportion of candidates who gain a first class. Much useful teaching is being done, but it may be doubted whether the students, or possibly even the teachers, fully recognise that if technical training is to be of real service to a profession and those who follow it, such training must combine thoroughness as regards knowledge of principles with accuracy as regards knowledge of working details.

SECTION B.

It is a matter for regret that a large number of students do not take advantage of these examinations. The average of technical knowledge shown in the papers placed before me is higher and more general than I have hitherto observed, and I feel sure it would be an advantage if a greater proportion of those studying "process" photography were induced to enter for these examinations and tests.

THE THORNTON-PICKARD PRIZE COMPETITION, 1904.

The following is the list of prize-winners in the competition:—

Class I. (Six Prizes of £5 Each).—For pictures taken with any of the Thornton-Pickard Cameras, fitted with any pattern of Thornton-Pickard Shutters, except "Focal Plane" and Stereoscopic.—Miss Sybil Aird, Eastbourne; Mrs. G. A. Barton, Four Oaks, Birmingham; Mr. O. P. Topham, Bristol; Mr. W. Bratherton, Barrow-in-Furness; Miss Agnes Tomlinson, Chichester; Mr. Duncan Robertson, Camera Club, London.

Class II. (Five Prizes of £5 Each).—For pictures taken with either pattern of the Thornton-Pickard "Focal Plane" Shutters.—Mr. A. H. Hawke, Helston; Mr. Maurice Brown, Belfast; Mr. A. W.

Sargent, Cardiff; Mr. Ettore Merli, Torre Annunziata, Italy; Mr. H. A. Game, London.

Class III. (Six Classes of £5 Each).—For pictures taken with any of the various patterns of the Thornton-Pickard Shutters, except "Focal Plane" and Stereoscopic.—Mr. Oscar Hardee, Chislehurst; Mr. F. Morland Andrew, Abingdon-on-Thames; Mr. Oscar Hardee, Chislehurst; Mr. J. Shaw, Manchester; Mr. Albert Durn, Wotton-under-Edge; Mr. F. A. Hargreaves, Waiapu Bay, New Zealand.

Class IV. (Three Prizes of £5 Each).—For stereoscopic pictures taken with the Thornton-Pickard Stereoscopic Shutter.—Mr. R. Fortune, Bowling, N.B.; Mr. W. Wilkinson, Derby; Mr. W. P. Thomson, Whalley Range, Manchester.

SUBJECT AND DESIGN.

"WHAT are the real elements of pleasure in a picture?" is the pertinent question asked by a writer in the "County Gentleman." One thing we may say for certain; that is, that they are different to different observers. To take two cases, the man who is pleased with design is probably very different from the man who delights in subject. If a given space is decorated with a good pattern, it becomes more pleasing to the eye; and it is this fact that lies at the root of all composition. The harmony of sweeping lines, the balance of masses, the contrasts of colour, all go together to make up a good pattern. But all these elements of design have another function as well—they are intended to represent, or rather to suggest, some subject. It is the trained and educated mind that appreciates design, but subject can be grasped far more easily. We all know of the farmer at the Royal Academy who is rejoiced to recognise a fine field of beans, or a group of cattle; yet he is horrified at discovering that the value of the picture exceeds that of the cattle themselves. It is quite true, however, that to a very large number of people their pleasure in looking at a picture is represented by their power of recognising the subject. I do not mean merely that they know whose portrait they are looking at, but that, on looking at the picture, they recognise that the effect suggested by the artist is a part of their own experience.

They have seen the waters of the lake reflecting the hills in just that very way; they have been delighted one winter's morning at seeing the sparkle of the sunlight on driven snow contrasting with long pale shadows that reflect the blue light of the open sky; and they are intensely pleased to find an artist has noticed just that very thing, and made a picture of it.

"Yes; how true to nature! I have seen that very effect myself," is far more often the ground of appreciation than is any insight into the technical powers that enable the artist to embody his idea.

This is one reason for the great popularity of domestic scenes. A photographer or painter who can satisfy his own artistic feelings through the instrumentality of familiar scenes and objects is sure of a wide acceptance. But, after all, the picture is good or bad—a work of art or a mere triviality—just according to its treatment, and not because of its subject.

It is here that the painter of a picture of this kind has so great an advantage over the photographer—he can more easily avoid being commonplace. Many photographic pictures of familiar scenes fail because they give the trivial details with such insistence. This is recognised by pictorial photographers, who with increasing skill try to eliminate what they wish to reject by after work on the negative and print. Their very skill leads them into pitfalls. It cannot be too strongly insisted upon that all such tampering with the actual image brings with it a deterioration of quality of surface, and too often a falsification of tone which more than outweighs the gain in breadth of effect.

THE premises of Mr. Wheeler, photographer, 106, High Street, Oxford, were the scene of a fire on Saturday evening last. The call was received by the Brigade at five minutes to nine through the police telephone, and the hose truck was soon on the spot. A length of hose was run up at the back of the house to the top room, where the fire broke out. It was quickly extinguished. The top landing was seriously damaged by the water and smoke, whilst the room was quite burnt out. The property belongs to Oriel College.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
7.....	South London Photo. Society...	<i>A Ramble Round the Tower</i> London. Mr. A. Bedding.
7.....	Luton Camera Club	<i>Colour Photography.</i> Illustrat Messrs. Ranger Shepherd & Co.
7.....	Bowes Pk. and Dis. Ph. Soc. ...	<i>Observations Upon Picture Maki</i> Mr. F. C. Tilney.
7.....	Southampton Camera Club	<i>Lantern Slide Making.</i> Illustrat Mr. J. A. Hodges, F.R.P.S.
8.....	Birmingham Photo. Society ...	<i>Demonstration of Oer and Und</i> <i>Exposed Negatives.</i> Mr. A. Tucker, F.G.S.
8.....	Nelson Photographic Society ...	<i>Animated Photography.</i> Mr. Alb Wilkinson.
8.....	Architectural Asso. Cam. Club	<i>Colour Photography for Architec</i> Mr. Chas. B. Howdill, A.R.I.B.A.
8.....	Glasgow Southern Photo. Assn	<i>Behind the Scenes; or, the Camera</i> the Wild West. Mr. J. W. Eadie.
9.....	North Middlesex Photo. Society	Exhibition of R.P.S. Competition Pri The Uses to Advantage of Ori chromatic Plates. Mr. T. The
9.....	Boro' Poly. Photo. Society	Baker.
9.....	Crick'wood Photo. Society.....	<i>Beginners' Night.</i>
9.....	G.E.R. Mechanics' Institution	<i>Pictorial Photography.</i>
10.....	Batley and Dis. Photo. Soc. ...	<i>Bromide Enlarging.</i> Demonstrat Mr. S. Swinden.
10.....	Watford Camera Club.....	<i>The X Rays.</i> Mr. E. H. Jacks <i>Pictorial Photography.</i> Mr. Linsley. <i>Stereoscopic Photograp</i> Mr. Hodgkins.
10.....	Rugby Photographic Society ...	<i>Hints on the Photography of Archi</i> ture. Rev. W. H. Payne-Smith. M.
10.....	Hull Photographic Society	<i>English Ecclesiastical Architectu</i> Mr. C. B. Howdill, A.R.I.B.A.
10.....	Gateshead Camera Club	<i>Development of Plates, and the</i> <i>Improvement of Faulty Negativ</i> Demonstrated. Mr. A. B. Gardiner.
10.....	Rodley and Dis. Photo. Soc. ...	<i>Re-touching.</i> Mr. J. Wav.
10.....	Richmond Camera Club.....	<i>Colour Photography.</i> Demonstrat Messrs. Sam. r Shepherd & Co.
10.....	London and Prov. Photo. Assn	<i>Open Night.</i>
10.....	Liverpool Amateur Ph. Assn.	<i>Talks on Picture Making.</i> Discussi Mr. Fred Burridge, R.E.
11.....	Watford Photographic Society	<i>Lectures by Members.</i>
11.....	Wakefield Photo. Society	<i>Carbon Process.</i> Demonstrated. R. Stockdale, M.A.
11.....	Boro' Poly. Photo. Society	<i>Lantern Slide Making.</i> Mr. W. Pa Lectures, illustrated by Enlar ment, Messrs. W. H. Carr and Walker.
11.....	West London Photo. Society ...	

CAMERA CLUB.

ON the 27th ult. Professor Flinders Petrie, the eminent Egyptologist who is by no means a stranger to the Camera Club, gave a most interesting lecture upon "The Genesis of Art in the Land of the Pharaohs." There is something stimulating in the word "art" connection with photographic meetings, and a very large audience assembled to hear the account of some of Professor Petrie's latest discoveries. He spoke of things which happened no less than nine thousand years ago, a remote period which, until the land of Egypt gave up its secrets, was generally supposed to belong to prehistoric times. But the labours of the Professor and of some few others have put the clock back a bit, and we now know that, when Europe was overrun by savage hordes but little removed in intelligence from the beasts which they hunted, Egypt was far advanced in the arts of civilisation.

It was to these arts that the lecturer directed attention, and when we add that he is quite an expert photographer, and can illustrate his remarks by lantern slides taken of the objects which he describes, many of which were first exposed to the light of day by his own hands after their sleep of many thousand years, it can be imagined that his lecture was full of interest, and was listened to with open ears.

If this early people had not expressed their artistic ideas upon such an imperishable material as baked clay, we should have known but little of their capabilities, and here we see how they ornamented the most elegant form with the sculptured representations of animals, and later on, of human beings. Then they knew many other arts, that of weaving, for instance. Professor Petrie showed on one slide the fragment of a piece of mummy cloth, contrasted with a piece of the finest of present-day cambric, and so far as excellence of manufacture went, there was nothing to choose between the two. Possibly the seventy-century example was the better of the two, for the Egyptians had not learned the art of sophistication; the weighting cloth by the use of earths had not occurred to them.

Then there was the jewellery—the oldest jewellery known, discovered on the mummied arm of an Egyptian princess. To this jewellery the lecturer assigned the date 4700 B.C., and it is in as good condition to-day as it was when first made. One of the bracelets is of beads, and a more elaborate one is composed of flat links, made alternately of gold and turquoise, and what is very remarkable is that the metal is soldered, and is of most excellent workmanship.

An ivory statue, excellently carved, of one of the first kings of Egypt was another valuable find, and we were told how this little image was so fragile with age that it had to be cleaned with nothing harder than a camel-hair brush. Its photograph showed that it was of high artistic merit, and as the name of the king it represents is upon it there is no doubt as to whom it is meant for.

Professor Petrie aroused much interest by his explanation of the kind of photographic apparatus which he employs. He has a long extension camera, with a front so made that it can be made to occupy any position. For most of his work he uses an old style Ross R.R. lens, supplemented with a telephoto lens for work difficult of near approach. Below the camera he has a receptacle holding a hundred films, and these he changes in daylight—one by one—by means of an attached sleeve. He showed a large number of photographs of difficult subjects taken with this camera, not only in Egypt, but in other countries. The lecture was listened to with great attention, and Sir H. Treman Wood occupied the chair.

CROYDON CAMERA CLUB.

NOVEMBER 26.—A large attendance gathered to hear Mr. F. W. Hicks give a practical demonstration on the making of positive transparencies intended for the subsequent production of enlarged negatives. An expert worker, and without the superfluity of "talk," which on occasions distinguishes some pictorial exponents of the camera, all he had to say was instructive, to the point, and was listened to with attention. If the original gradations of the small negative were to be preserved in the enlarged one, then an intervening carbon transparency, he thought, was almost compulsory. Trouble might, and frequently did, occur with reticulations of the film, but these, as a rule, did not record themselves, provided a daylight enlarging apparatus was employed. With artificial light and a condenser, the opposite frequently prevailed. In most cases it was, however, of no moment whatever if the relative gradations were altered. Such alteration might, as a fact, be an improvement. Under these conditions he invariably used a slow plate with a fine grain, such as "Wratten's Ordinary," and preferred metal as a developer, owing to its slight tendency to clog the shadows. A softly modelled transparency, free from fog or veil, and not too contrasty, should be aimed at, and the worker should not mind wasting several plates until the desired result was obtained. Several excellent transparencies were exposed, developed, and fixed, and passed round for inspection during the evening, and the various methods of printing in skies were explained and illustrated.

In the discussion which followed Mr. Sellors drew attention to the grain of the plate often obtruding itself most unpleasantly in the enlarged negative. In order to minimise this tendency he slightly enlarged the transparency. Mr. Hicks, in reply, said he did not think the results compensated for the extra trouble involved. It was not a case of the grain of the transparency showing so much as that of the original negative, which was generally a fast one, and possessed a far coarser deposit. If hand work was required to be done on the transparency then, of course, the case was different.

CAMBRIDGE PHOTOGRAPHIC CLUB.

UNDER the chairmanship of Mr. F. J. Stoakley, vice-president, a meeting of the Cambridge and District Photographic Club was held at the Prince of Wales Hotel on Tuesday evening last week, when the medals secured by competitors in the recent exhibition at the Bournemouth Exchange were distributed by Mrs. McKenny Hughes. Previous to the presentations there was an animated discussion on subjects of interest to members, and several promises of addresses and demonstrations in the coming winter were made.

Mr. W. B. Redfern introduced Mrs. Hughes with the remark that she took great interest in photography, being herself an artist of no mean ability.

Mrs. McKenny Hughes, having presented the medals, expressed the great pleasure with which she attended the meeting, and remarked upon the delights experienced by all who took up photography as a hobby. The art gave scope for the exercise of individuality in no slight degree, and the possibilities of stamping individuality upon one's work were numerous. Though the camera could never take the place of the brush, it could be used to seize some passing effect, some combination of light and shade, some characteristic mood of a person, so as to produce in their mind the sensations that inspired the artist. This power of artistic interpretation was the highest form of art. Mrs. Hughes also referred to photography as an auxiliary of natural history work, and hoped that those beautiful pictures of animate life might take the place of collections of dead creatures.

The cup that was presented by Mr. A. W. Smith for the best picture in the local classes, became the personal property of the Rev. H. R. Campion, who has won it on three successive occasions.

Mr. Redfern proposed a vote of thanks to Mrs. Hughes, and made an emphatic reference to the utter unsuitability of the room in which the exhibition was held. Entrance to the room was gained by passing up stone steps, which always made him feel that he would find a warder waiting at the top, and he was sure that the nature of the approach debarred many from visiting the exhibition. Then it was quite impossible to light the room properly, for there was no daylight, and electric light was unsuitable during the day. He strongly urged the club to do their utmost to obtain another room from the Horticultural Society, for the present one was quite unworthy of the time and trouble spent in putting up the pictures, for it failed to do them justice. (Hear, hear.)

Mr. A. C. Haddon spoke respecting the Photographic Survey of Cambridgeshire which was being taken in hand by the Antiquarian Society, and urged all members of the club to join them in this work. The opportunities in this connection were practically unlimited, and it was work which every member ought to take up. He trusted that they would do all that they could to further the scheme, the success of which they could very materially affect.

The Secretary stated that the Council had the matter in hand and would very shortly issue to the members the appeal which the Antiquarian Society had sent. Steps were being taken to interest members in the survey.

Prof. McKenny Hughes, in a racy speech, impressed upon the members the very great help they could give in the matter of records. He pointed out that in many of the out-of-the-way villages in the county there were distinctive types of people which ought to be recorded in this way, and spoke of the great help that could be thus given to the Anthropologists such as Dr. Haddon. Referring to this one particular science, he instanced how on many occasions material help would have been found if he could have had some of his "finds" photographed as soon as discovered. Those who unearthed these early remains and curious earthworks were very seldom photographed, and he looked to members of that club to give their assistance in helping to put on permanent record the interesting and valuable discoveries which were continually being made in the county.

Dr. Bansall proposed a hearty vote of thanks to Prof. and Mrs. Hughes, which was carried by acclamation.

FORTHCOMING EXHIBITIONS.

November 2, 3, 4, 5.—Newark Photographic Exhibition. Secretary, L. C. B. Appleby, Barnbygate House, Newark.

November 2-23.—Plymouth. Hon. Sec. Photographic Section, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 9.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, 52, Frederick Street, Sunderland.

November 17-18.—Braintree and Bocking Camera Club. Hon. Sec. W. H. Tilston, 81, High Street, Braintree, Essex.

November 17-19.—Darwen Photographic Association. Hon. Sec., J. G. Thomas.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarock Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 12-14, 1905. Boston Camera Club. Hon. Sec., H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Sec. John B. Parnham.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

WOODFORD Photographic Society.—This Society held its annual general meeting on Wednesday, October 19. The election of officers for the session 1904-5 resulted as follows:—President, Mr. H. Wilmer. Vice-presidents, Messrs. A. Ziegele and A. Horsley Hinton. R.P.S. Affiliation Delegates, Messrs. E. Marriage and E. C. Winney. Council, Messrs. W. L. F. Wastel, G. H. Grimsell, E. H. Carpenter, and W. Ormel. Lanternist, Mr. Reginald A. Malby. Hon. Secretary, Mr. F. G. Emiler. Assistant Hon. Secretary, Mr. E. H. R. Hillsworth. It was announced that the photographic survey of Woodford, which this Society undertook, was now nearing completion, and a Committee was chosen to finish the work.

Commercial & Legal Intelligence

SPEIGHT, LTD. (Photographers, London).—Issue on October 17 £2,550 debentures, part of a series created June 25, 1904, to secure £10,000, charged on the company's property, present and future, including uncalled capital (if any). No trustees. Total amount previously issued of same series, £7,450.

BERNARD COOPER, LTD.—Capital, £2,000 in £1 shares (500 preferred). Object: to carry on the business of photographers, fine art and photographic dealers, picture-frame makers, dealers in photographic apparatus and accessories, plates, papers, mounts, chemicals, etc. No initial public issue. B. Cooper is the managing director. Qualification, £25. Remuneration as fixed by the company.

THE statutory meeting of the creditors interested under the failure of Charles Hicks Evkyn, of 49, Eaton Terrace, Eaton Square, was held at the London Bankruptcy Court on Friday last before Mr. Bowyer. Debtor estimated his liabilities at £1,000, and his assets at £90. The debtor stated that in 1892 he received £10,000 under the will of his grandfather, but he lost about £3,000 of it in business in Algiers, and he had also lost large sums in connection with various companies. He was at present a partner in the Division Photogravure Company, of 21, Farringdon Avenue. He put £2,000 into the business, and now acted as the business manager. The bankruptcy proceedings did not relate to that business as a whole but only to himself personally. He alleged his present position had been caused through the failure of a printing company and an advertising agency. The estate was left in the hands of the official receiver for summary administration in the usual manner.

Re William John Le Couteur, photographer, 16, Brook Street, Hanover Square, and 312, Regent Street, W. The first meeting of the creditors concerned under this failure took place at the London Bankruptcy Court on Monday last before Mr. Chapman. It appeared that the debtor was at present without any occupation. About five years ago a company was formed to take over his business called The Photographic Association, at 16, Brook Street, W., and he became managing director at a salary of £6 per week. In November 1899, he was made bankrupt, on the petition of a Mr. Scott, in respect of a debt contracted by him on behalf of the company. In November, 1902, further debentures were issued by the company to Captain Henry Connop and Captain Richardson, directors of the company, and debtor was then induced to sign another agreement with regard to his services as manager, under which his employment was to cease upon the company going into liquidation, the business being sold, and that he was to be free to work apart from the company. Under that agreement he worked until June 1903, when the debenture holders foreclosed, and carried on the business until the liquidation of the company in November, 1903. Debtor acted as manager for the receiver for four or five months when he was dismissed. The company's business was afterwards sold to the petitioning creditor. Upon the expiration of the company's lease at 16, Brook Street the company removed, and a Mr. Whitehead took the premises on behalf of the debtor's wife, who still carried on business there as a photographer. Debtor assisted his wife in the business, no arrangement having been made for his remuneration. About April last the purchaser of the business from the company made an application to the Court for an injunction restraining debtor from practising as a photographer under the first agreement with the company. Debtor defended the action, on the ground that the first agreement was null and void and that the company had gone into liquidation, but upon a technicality he lost the action, with the result that he had to pay £130 in respect of costs. A bankruptcy notice was served upon him for that amount, and the receiving order was afterwards made. Income had amounted to about £300 a year for the last five or six years. He was made bankrupt in the High Court in 1899, and dividend had been paid to the creditors under the bankruptcy. He attributed his present position to the costs incurred in the action by the petitioning creditor. After some discussion it was decided to adjourn the meeting.

News and Notes.

NOTTINGHAM Camera Club.—At last week's meeting of the Nottingham Camera Club (Mechanic's Institution), Mr. E. H. Aitken delivered a practical address on "Printing, Developing, and Toning Bromide Papers," the most interesting portion of which was a demonstration of the newer method of toning with sodium sulphide.

LONDON and Provincial Photographic Association.—On Thursday last Mr. Freshwater showed Prof. W. R. Woods' new pictures of colour photography by diffraction; he also explained the method by which they were produced. The members present were much interested in the process, and considered the colours produced to be very pure.

NORTH Middlesex Photographic Society.—At Hanley Hall, Crouch Hill, on October 26, Mr. F. J. Mortimer lectured before the above Society on "Scillonian Pictures." His many visits to this semi-tropical region enabled him to illustrate his lecture with over two hundred slides, but the most interesting were, perhaps, those which represented the subject of wave studies and seascapes.

LIVERPOOL Amateur Photographic Association.—A meeting of this association was held on Thursday evening last in the club rooms, Thorne Street. Mr. A. W. Beer delivered a lecture, entitled, "Mosses from some Old English Stones." The address, which was illustrated by lantern slides, dealt specially with Stonehenge, Hampton Court, the New Forest, and Warwick Castle.

LAST week there was delivered in the rooms of the Dundee and East of Scotland Photographic Association the first of a series of lectures to beginners. The lecturer was Mr. Peter Feathers, and he took for his subject "The Camera and Lens," giving an interesting description of the mechanism and working of the photographic apparatus.

CAPTAIN SCOTT, R.N., and the officers of the "Discovery" Antarctic Expedition will be present at the opening of the Antarctic exhibition of water-colours, photographs, and other articles of interest used in the South Polar regions during their recent expedition, which will take place at the Bruton Galleries, Bond Street, Friday (Friday). Sir Clements Markham, President of the Royal Geographical Society, will open the exhibition at three o'clock.

FACEING THE CAMERA.—When William Watson and Robert Bentley, of Leeds, were brought before the Stipendiary Magistrate last week, on a charge of manufacturing counterfeit coin, the Deputy-Chief Constable, Mr. Dalton, asked that an order should be made for the photographing of Bentley, who objected to face the camera. Bentley refused because he said the police had already a photograph of him in their possession, and whether it was a young or old one they would not get another. Watson supported his fellow-prisoner's objection by stating, with much emphasis, that the man could not be photographed before trial. "That was the law in 1895, but it has been altered since then," remarked the Stipendiary. "Oh! of course, you are sure to alter it," retorted Watson. The Stipendiary: "You haven't seen the regulations made in 1896." "Then read 'em out, read 'em out like a gentleman," exclaimed the old man, excitedly; adding that they wanted to photograph him simply to aggravate him. The men were remanded for a week, when the committal to the Assizes will take place.

"The Three-Colour Process, as Applied to Letterpress Printing," was the subject of a lecture by Mr. Charles W. Gamble, of the Manchester Technological Institute, at the Technical Schools, Leicester, on Friday last. Mr. Gamble, in his preliminary observations, pointed out that the desire to render pictures in colour was not in any sense a new one. Ruskin had told them that wherever men were noble and free they love bright colour, and wherever a picture was produced there had always been the desire to give a reasonable transcript of the colours. About 100 years had now elapsed since Josiah Wedgwood made his experiments, which constituted a record of light upon sensitive substances. In sketching the history of photographic processes, the lecturer described the principle of three-colour photography expounded by James Clerk Maxwell in 1861, and which is the basis of all photography in natural colours. Mr. Gamble also explained at great length the three-colour process as applied to letterpress printing, his remarks being made exceedingly interesting by lantern slides, and a large number of examples in monochrome and colour.

TREATING THE SURFACES OF PLATINUM PRINTS.

To the Editors.

Gentlemen,—I have lately tried the effect of rubbing the surfaces of platinum prints with encaustic cerate and find this greatly improves the brilliancy of the print, so much so that I am inclined to treat all my platinotypes in this way. Can you, or any of your readers, say if prints treated in this manner would be likely to lose the purity of the whites in time? There appears to be no loss so far.—Yours truly,

F. S.

November 1, 1904.

[Our correspondent will probably find that the whites of his prints will go yellow in time.—Eds. B.J.P.]

A PROBLEM.

To the Editors.

Gentlemen,—As a constant reader of your paper you bear with me in writing you in confidence. I am a Baptist minister. Unfortunately, for some time I have been out of a pastorate through no fault of my own, but through the weakness of our denominational system. I am also a competent photographer in all its branches, and have been for sixteen years.

Being without a pastorate I have resorted to my business among private friends. I feel it is only honourable so to act rather than be in any way dependent upon charity.

I write you for your advice, which I trust you will give me, and for which I shall be grateful.

Do you know of a good opening where I could start business without incurring much expense? I have all needful apparatus to work with. Should prefer the South Coast, or do you know of any opening to manage a business? I need not say I am capable as a business man.

If in my anxious position you can assist me I shall esteem it a great favour.

You will understand me when I say I am not anxious for a mere journeyman's position, but one of trust, and in which I could merit respect. I have been well known and respected for many years. I have a wife and one daughter, both acquainted with the business, and will be a valuable help.

Kindly forgive this lengthy letter, and oblige me, should you know of anything suitable, or a small business.—Faithfully yours, C.

November 1, 1904.

[Why does not our correspondent advertise in the outer columns of this JOURNAL? We are sorry we cannot further help him in the matter.—Eds. B.J.P.]

ANOTHER PROBLEM.

To the Editors.

Gentlemen,—Your article, "A Press Side Line," in the B.J.P. of October 14, has interested me very much, and I am taking the liberty of writing you for a few hints on the subject. Owing to dullness in the photogravure line and other reasons over which I had no control I find myself out of a situation, and things in that line seem to be at a very low ebb.

I have had nearly four years' experience in negative making for photogravure and half-tone, and my work has been of a varied character, including neg. making up to 40in. by 30in. (direct ortho) from paintings, etc., copying coloured originals, specimens of the arts and crafts in hammered copper, etc.; laces and coloured fabrics; and for catalogue illustration for some of the leading drapery establishments. Previous to this I had several years' experience in general professional portrait photography in and out of doors, and I have not neglected this latter branch during the past four years.

Of course, as you hint in your article, other qualities are necessary to make a success of this branch.

A dark-room and work-room in the City would be a necessity, would it not?

If you will kindly favour me with your advice I will esteem it a great kindness.—I am, yours, etc.,
"E. N."

November 1, 1904.

[Our advice is simple. Either advertise, or call on the editors of the illustrated papers with specimens of your work.—Eds. B.J.P.]

SPURIOUS SPECIMENS.

To the Editors.

Gentlemen,—Re your correspondent "P. W."—I have a similar thing here. An amateur, who for some time had been snapping people in spare time, opening a studio directly opposite me, and filling his window with absolutely the finest carbons it would be possible to obtain. Of course, they are not his work—some of the children's faces he has in have taken prizes. Out of the whole show, three, or possibly four, are people he has taken, printed, etc., away.

Photography is far too easy. It is not difficult now-a-days to guess the right exposure and get a negative. Then, like my opposition, it is sent away to be retouched, printed, mounted, and worked up, and is then quite equal to, if not better than the ordinary professional work. Nobody can blame an amateur for wishing to get on, but when it is done by false specimens, etc., etc., you can almost wonder if it is not equal to "obtaining money under false pretences," for, as in this case, the work cannot always be good, even if it fails in the posing, etc.—Faithfully,
November 1. 1904.

TEN BY EIGHT.

NOTHING LIKE BUTTONS.

To the Editors.

Gentlemen,—We believe matter published in the Press is invariably regarded as fair material for comment, and in alluding ambiguously to a case which we recollect reading in the photographic journals we must disclaim the least idea of hurting the feelings of anyone, our intention being solely to give force to a "point" in our argument.

Assuming that your correspondent "E. T. Vanderbilt" correctly states the case in which he was fined, he appears to have been hardly treated in this particular instance.

This gentleman's letter displays great animus, and, as usual with most people when writing in the heat of temper, he becomes illogical, and, consequently, amusing, as while congratulating himself on never having "descended to our level," and charging us with what he is pleased to call "mud-throwing," he endeavours to the utmost of his ability to bespatter us with this detectable compound, and indiscriminately mixes a few stones with it.

Making allowance therefore for your correspondent's evident state of irritation, we propose only to seriously notice those assertions which in their present crude form are calculated to create erroneous impressions.

Re "Giving away Enlargements."—Some years since there were three firms in Bold Street, (one was Barraud's) presenting opals or enlargements with each dozen cabinets. Now the public are keenly watchful for any "bargain," and finding many of our clients taking advantage of these offers, we deemed it necessary for the protection of our own interests to do something of the kind, so we included with every 25s. order, a boudoir-size bromide. This we did for a limited period only, and when we considered our object attained, we withdrew these pictures. Liverpool is not like Dublin, or the West-End of London; the commercial spirit is strong here and must be reckoned with.

In our first letter to your paper we remarked that certain "high-art" photographers write continually to the best people here (chiefly ladies) offering sittings. So far, we have never done this, but your correspondent's statement would lead readers to a different conclusion. The "free invitations by the hundreds" are those issued annually to the children attending the Lord Mayor's fancy dress ball. This invitation scheme was originated by a late Bold Street firm, and we, in common with all the principal photographers here, were compelled in self-defence to follow suit, or see hundreds of our clients go elsewhere. Beyond this, and occasional requests for sittings to Church dignitaries, Lord Mayors and professional celebrities for publication purposes (perfectly legitimate business, and the custom of photographers everywhere), we have as yet offered no free sittings. We say "as yet," because we shall probably soon be forced to "move

with the times" and meet this insidious form of competition in the only possible way.

These photographers are not of your correspondent's class, and they do not appeal to his clients he can afford to view their methods with equanimity, or, as he politely puts it, he need not "descend to their level."

We submit, therefore, that "Mr. Vanderbilt" is not qualified to judge, or appreciate, our position in this matter.

In concluding this correspondence—as far as we are concerned may we add that about seven years ago we proposed to several of the leading Liverpool photographers what we considered might prove an effective means of preventing local photography from drifting into its present condition, viz., a scheme of amalgamation. It was rejected by them, and its revival here is impossible now, but we venture to think there are still cities where powerful combinations might do much to redeem the present position of affairs and to establish (at all events locally) the status of "photography as a profession."

With our best thanks to you, gentlemen,—We are, yours faithfully,
MEDINGTON'S, LIMITED

29, Bold Street, Liverpool.

THE "STEADMAN" EXPOSURE SYSTEM.

To the Editors.

Gentlemen,—A good judge is said to "never give his reasons," and Mr. Steadman in giving the reasons for his elaborate subject classification reveals the unsoundness of its basis.

He starts by acknowledging the possibility of correctly rendering on one plate a subject having foreground, middle distance, and bird's-eye plane (I adopt his own peculiar phrase to avoid confusion), then he is to say the feeble contrast in the bird's-eye plane is correctly rendered on the plate as it is seen. He now presumes that if this bird's-eye view is photographed on a plate without middle distance or foreground, the rendering which was correct before is now incorrect, and that it is necessary to secure more contrast between tones than appear to the eye, in order to "cover some considerable part of the natural scale of tones." It is this presumption which is unsound. The delicate lights and shades on a snow-drift may be perfectly and correctly rendered on a plate, and yet only a small part of the "natural scale of tones" utilised. And even assuming that the increase in contrast between the tones is desirable, Mr. Steadman lets out that he secures it by "forcing the greatest effect up to the desired point of density by longer development or intensification." He does not seem to be aware that it is the length of development and not the length of exposure (or subject classification) which gives the power to spread the tones out to a greater or a less range, and that his elaborate classification is useless for this particular end.

The only need in exposure is to bring the greater part of the tones of the subject within the "correct exposure" range of the plate, and any subject classification which does more than secure this is unnecessary. When photographing distance alone it may be well to lessen the exposure (say one half) to secure this desired end. Any variation in contrast of tones is a matter to be treated in development, not in exposure.

It is a little difficult for plain men, who (to use an architectural simile) are more used to Early English than to Flamboyant style, to follow Mr. Steadman in all his flights. But perhaps he will explain his image of "the brightest professor of physics" with "no unit of actinism," wondering whether the light is strong enough or not, to make a snap shot; and how this image can exist side by side with "any child of school age with any good meter or sensitive paper learning in an hour or less to expose correctly."

What does he mean by saying there is no uniform system of opacities measurements? Any photometer maker could have told him differently.

What does he mean by saying we have no uniform system of diaphragm markings, when all English makers use the standard of the Royal Photographic Society? Even in plate-speed markings (uniformity in which is yet open to improvement) no one would suspect from Mr. Steadman's assertions that nearly half the English makers mark their boxes by the most advanced system—that of Hurter and Driffield.

I certainly say "amen" to the plea for greater uniformity in phot

graphic standards, but why shut our eyes to the advances already attained in that direction?—Yours truly,
ALFRED WATKINS.
Hereford.

October 31, 1904.

SOME PECULIARITIES OF DYES WHICH PRODUCE TOTAL SPECTRUM SENSITIVENESS.

To the Editors.

Gentlemen,—I am sorry to encroach once more on your valuable space in reference to my article on dyes which produce total spectrum sensitiveness, and would not do so had not further experiments gone to substantiate the data laid by me before your readers. Of these I trust you will receive an account in due course. Mr. Wall's omission to notice or explain the fact which I pointed out, that his letter only corroborated my statements instead of contradicting them, is so weak as to want no comment on my part.—I am, yours faithfully,
T. THORNE BAKER.

16, Rutland Park Mansions, Willesden Green, N.W.

October 28, 1904.

[This correspondence must now cease.—Eds. B.J.P.]

DRYING NEGATIVES.

To the Editors.

Gentlemen,—Re your paragraph "Drying Negatives Quickly" under "News and Notes." As you invite discussion of the subject and go so far as to say you would "be much obliged" to receive remarks on the matter, I, for one, cannot resist the temptation to add to your editorial happiness by sending you a few results of actual experience. It is so general for writers of books and articles, who, perhaps, have not really practised what they are writing about, to say "so and so may be done." This is particularly noticeable, by the way, in lantern slide books, and I think the writer, who speaks of drying-off negatives by soaking in methylated spirit for two minutes, is wise to qualify his statement by the subjunctive clause, "if the spirit is strong enough." I have heard something about a seafaring tale which would have been longer if a certain bowl had been stronger.

And now with regard to methylated spirit. It can usually be purchased up to a strength of 64 deg. overproof, at least, I always made a point of selling that strength myself, but I do not suppose the kind sold at oilshops would stand that test, and, moreover, one always runs the risk there of having it measured out in a dirty measure, perhaps previously used for some oily substance.

Owing to our teetotal friends in introducing prohibition on Sundays, we are compelled now to have methylated spirit which is totally unfit for use in many of the more delicate arts and manufactures. It was formerly (some years ago) rendered unpotable by the addition of wood naphtha, which, not being of an oily nature, did not detract from the usefulness of the spirit. It was found by the Excise that a taste was acquired for this as a convivial beverage, especially in those prohibition towns in the North where the indulgence in their favourite whiskey was barred to them on Sundays. To prevent this great loss to the revenue (about 15s. a gallon) the Excise then ordered it to be mixed with mineral naphtha, a most nauseous, but, unfortunately, also an oily substance, and for this reason very objectionable for drying off plates and prints. By making proper application the old form can still be obtained, but the person applying, must, I think, satisfy the Excise that he wants it bona fide for scientific and not bibulous purposes. No doubt some of the greasiness might be precipitated by the addition of water and redistilling, but this would be one of the blackest crimes against Statute Law, and the penalties would debar the culprit (if caught) from any further practice of photography as a hobby.

Sometimes when, inadvertently, standing near Scotch gentlemen whilst they are indulging in their national beverage, I have thought, especially when the diluent was warm water, which, of course, brings off more aroma, that I could detect something more than a soupçon of naphtha. But then one is now and again startled at reading in our technical papers that some eminent distiller has been fined several thousand pounds for redistilling methylated spirit in his cellars. Rather too bad when he pleads ignorance of the law, besides, it deprives us of such a lot of whiskey.

To dry a plate in methylated spirit it should be washed quite free from hypo, preferably given a bath in saturated solution of chrome

alum, rocking the plate for about ten minutes. Then wash out the alum and dry off superfluous drops of water on both sides of the plate with corners of blotting paper, or absorbent cotton wool. The plate should then be rocked for at least ten minutes in methylated spirit, then moved rapidly in the air with a pendulum-like action of the arm, placed in a metal rack over a gentle warmth or in current of air. With regard to the latter, I think centrifugal motion would be good, and I can conceive nothing better in theory, I have not tried it, than fixing the plate on the fans of a ventilator such as are worked by electric motors.

With regard to dust, I think flics are more injurious to plates which are drying, and in the summer and autumn it is desirable to place the rack in a muslin safe such as is used for meat, etc.—Yours faithfully,
ALGERNON BROOKER.

Lewes.

October 28, 1904.

[We are obliged to Mr. Brooker for his interesting letter. The remarks on drying negatives to which he refers were quoted from the "Westminster Gazette."—Eds. B.J.P.]

STALE PLATES.

To the Editors.

Gentlemen,—In your issue of the B.J.P. for September 9, a letter appears signed "Enquirer," on the above subject, and I quite sympathise with him and with anyone who has the misfortune to purchase old and stale plates whilst unsuspectingly believing they are getting fresh.

Would not a good remedy for this be for the makers to mark every box of plates with the date of issue of its particular batch? This plan might appear to have its drawbacks to dealers, and certainly a few might have to suffer a little at first, but the thing would very soon right itself and work out better for all parties concerned. I feel sure that the plate-makers who are bold enough to adopt this plan, and draw attention to it, will score by it, and so will everybody else in the long run. At any rate if this plan could be adopted, purchasers would only have themselves to blame for buying "stale plates."—I am, gentlemen, yours faithfully,

LESLIE W. FORD.

Queenstown, Cape Colony.

October 10, 1904.

PLYMOUTH Photographic Society's winter session was inaugurated at the Athenæum on Friday evening last, with a presidential address and a lantern slide display. Mr. J. T. Johnson marked his election to the presidency by entertaining the committee at dinner at Little Efford on Saturday, and during the evening, Mr. Wilfred Grist was presented with a silver cigarette case, engraved with his monogram, as a souvenir of his honorary secretaryship during the last four years. An interesting programme for the session, with an exhibition of members' work, was announced.

CHRONIC X-ray Dermatitis.—Our esteemed contemporary, "The Medical Press," has a few words to say on this subject which may go far to allay the recently-raised fears of X-ray operators. It remarks:—"Certain daily newspapers have raised the ghost of a well-known malady—as is their wont—and have done their best to make the blood of the public turn to water with their turnip-headed wonder. The fact that workers with the Röntgen rays are subject to an extremely chronic, distressing, and incurable inflammation of the hands has at length penetrated the recesses of Fleet Street. The further fact that several cases of cancer have developed in connection with chronic X-ray injury seems to have inexpressibly inflamed the editorial imagination; the yellow press of the kingdom has been accordingly flooded with startling headlines, pictures, interviews, and bristling columns horrid with fact and fancy. Among the interviews we regret to see one with a Midland worker in the X-rays, who has apparently so far forgotten the unwritten rules of the medical profession as to furnish his experiences to a reporter to be published under his own name. The views of a London specialist have been quoted copiously in relation to a book, for which notice he is obviously not answerable. As a matter of fact the chronic dermatitis of Röntgen-ray workers has been known for a long time, and was described fully some six or seven years ago in the book which is the standard English authority on the Röntgen rays in medical work."

Answers to Correspondents.

- *** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- *** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

J. STEELE.—Better address Mr. E. Howard Farmer at the Polytechnic, 309, Regent Street, London, W. We do not undertake to answer letters by post.

W. B.—We think the work the reverse of refined, and are not surprised at the caricatured person feeling aggrieved. Our advice is to climb down handsomely and forbear that sort of joke in future.

COPYRIGHT.—A READER for 45 years writes:—"I have a 12 in. by 10 in. view of our old town-hall, which is copyright. I have now copied it for postcard. Will you kindly say in your very interesting paper whether it is necessary to register the copy in order to protect it?" In reply: If the 12 in. by 10 in. is registered in our correspondent's name no further registration is necessary.

REDUCING PLATINOTYPES.—F. V. HOWELL says: "I should be glad if you could give me a formula for reducing over-exposed platinotype prints." In reply: We know of no very successful method of reducing over-printed platinum prints without impairing their original quality. The simplest thing is to make fresh prints, and it is the cheapest in the end if time is of any value. This is the course we should advise you to adopt.

FOCUSsing HOOD.—"FOCUS" says: "I want something that would take the place of a focussing cloth (for 1/1 camera; a screen or hood; of course it would have to fit on to back of camera? Could you give me the names and addresses of a few firms most likely to make it for me?" In reply: Mr. F. Berresford, 14, Bridge Road West, Battersea, S.W., make a speciality of focussing hoods. Better write him for prospectus.

STUDIO QUERY.—"NEMO" says:—"On the other side I send sketch of two rooms I am thinking of taking for a studio, and shall be glad of your opinion as to the proposed arrangements and size for cabinets, full lengths, and heads and shoulders, and large heads 12 in. by 10 in.; also whether one or two —'s lights would be sufficient for exposures of, say, two seconds f./6.8." In reply: So far as dimensions are concerned, it seems that the rooms can be utilised. As we have had no experience with the light named we cannot say how many lights will be required for the proposed exposures.

BI-SULPHATE REDUCER.—"CONTRASTING" asks: "Would you kindly give me the formulæ and working instructions for reducing negatives, so as to give soft prints, with persulphate of ammonium, as I have some negatives which, though perfect in quality for plat., are too strong for C.C., which latter paper I am using; consequently they are at present useless for the purpose I have in view. Also, could you give an idea of cost of persulphate of ammonium?" In reply: Simply immerse

the negatives in a 5 per cent. solution of the persulphate until they are sufficiently reduced, then well wash. The price of the salt is about 3s. 6d. per pound.

LENS QUERIES.—"J. E. R." says: "I have one or two questions to ask. I have just ordered a studio these dimensions: 20ft. by 11ft., by 9ft. to eaves, 15ft. to ridge; 12ft. of glass top and side ground. The dark-room is 4ft. wide, extending to width of the studio, leaving me the space of 16ft. for operating. (1) Is the length suitable for cabinet portraits, full length, with a 13in. focus lens? (2) What focus lens would suit me best under these conditions? (3) Have I made a great mistake by not having 5ft. longer?" In reply: (1) No, it is not. To take full length cabinet portraits with a 13in. focus lens requires 20ft. between sitter and camera. (2) You will require a lens of about 9in. focus, but with that you must not expect pleasing perspective. (3) Yes.

RIGHT TO PUBLISH.—"PUBLISHER" says:—"Some time ago a lady called to have her photograph taken. After taking same to her order, I asked if I could take some extra for my own use. To this she willingly consented, and I exposed several plates. When shown the proofs of all she was so pleased with them, that she asked if she could order from any of them. This allowed her to do without charging for the extra position, and I also gave her two extra finished proofs. As I considered that those taken at my expense were my property, I allowed a gentleman to have the use of one for a book illustration. The book was duly published, and the lady now writes to the publisher threatening proceedings against him for publishing her photograph." In reply: It seems to us that when the lady gave you the extra sittings you gave her to understand that the portraits were for your own use, as, say, for specimens. She probably had no idea that the portraits were to be used as book illustrations or would not have sat. It is possible she has ground for action.

Patent News.

The following applications for Patents were made between October 17 and October 22, 1904:—

- Cameras.—No. 22,318. "Improvements relating to photographic cameras" (Benjamin Joseph Edwards.)
- Shutter.—No. 22,324. "Improved roller blind shutter for photographic cameras." (Adolph Richard Lange.)
- Developing Cabinet.—No. 22,370. "Developing cabinet." (W. Wood.)
- Apparatus.—No. 22,429. "Improvements in or relating to photographic apparatus." (Jethro Marsh.)
- Dark Room.—No. 22,454. "A portable dark room." (Edward Land Hall.)
- Plates.—No. 22,591. "Improved method of lifting plates applicable to developing and other trays for photographic use." (William Tylar.)
- Cameras.—No. 22,698. "Improvements in photographic cameras" (Abraham Kershaw.)

*** NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free (UNITED KINGDOM AND THE CHANNEL ISLES).

	s.	d.	
One Year	10	10	France, Belgium, United States, Canada, Australia, Africa, New Zealand, Newfoundland, Germany, Russia, Portugal, Spain, Italy, Egypt, India, China, Japan, &c. One Year ... 13s.
Half Year	5	5	
Quarter Year	2	9	

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies, and will number 1,612 pages, thus constituting the volume the largest yet published.

The following are some of the important features of the forthcoming volume:—

1. The frontispiece will be a portrait study specially produced for the Almanac by Mr. Furley Lewis (Medallist at the Royal Photographic Society's Exhibition, 1903).
2. The first editorial article, which deals with "The Present and Future Position of Photography," discusses the probable growth and expansion of all branches of modern Photography.
3. The second editorial article supplies a succinct illustrated history of the BRITISH JOURNAL OF PHOTOGRAPHY and its Almanac ever since their foundation.
4. Important articles and papers by the following, amongst many other well-known photographic writers, are included in the volume:—

Abney, Sir W. de W., C.B.	Dormer, J.	Hartmann, Dr. J.	Nelson, E. M.	Salisbury, J. W.
Baker, T. Thorne.	Duncan, F. Martin.	Henderson, A. L.	Neuhaus, Dr.	Salmon, P. R., F.R.P.S.
Baldock, J. H., F.C.S.	Dunmore, Edward.	Hepworth, T. C.	"Ons."	Selby, H.
Barker, J.	Dunmore, G. H.	Hett, Charles Louis.	Payne, A., F.C.S., FRPS	Slater, P. J.
Beasley, B. F., M.A., F.L.S.	Everitt, Philip.	Hodges, John A., F.R.P.S.	Perkins, Rev. T. M.A.	Smith, J. H.
Bird, J. J. S., B.A.	Foxlee, E. W.	Joly, Dr. J., F.R.S.	Pike, J.	Sutton, C. T.
Blaesbroek, G. Van.	Gamble, William.	Jourdain, Philip E. B.	Piper, C. Welborne.	Tilfor, J.
Bolas, Thomas, F.I.C., F.C.S.	Goodchild, Rupert.	King, Horatio Nelson.	Procella.	Wall, E. J., F.R.P.S.
Brosig, P.	Gower, H. D.	Leisk, J.	Rheinberg, Julius.	Wallace, Robert James.
Brown, G. E., F.I.C., F.C.S.	Graves, Frederick.	Lockett, A.	Richards, T. W.	Walsley, W. H.
Channon, H. J.	Hackett, J. T.	Mills, Edmund J., D.Sc., F.R.S.	Rohr, Dr. Moritz von, D.Phil.	Watkins, Alfred.
Clifton, Edgar, F.R.P.S.	Harris, Geo. T., F.R.P.S.			Valenta, E.

5. Numerous illustrations, including Portraits of many Celebrities in the Photographic World.
6. An exhaustive Review of recently introduced Photographic Apparatus.
7. Sections devoted to Practical Points; Epitome of Progress during 1904; Formulæ; and a great mass of Miscellaneous Information.

EX CATHEDRA.

"Instantaneous" Photography. The "Photo Gazette" for October 25 reproduces some very interesting instantaneous photographs of an exhibition of the "looping the loop" description, now being given at the theatre Folies-Bergère at Paris. A lady performer, in a car of the automobile pattern, takes a flight down a path inclined 45 deg.; the impetus is so great that when the car leaves the path in an inverted position, it takes a leap of about forty feet in the air, to a continuation, and there, in closing its journey, is brought again into its normal position upon reaching the ground.

* * *

A New Lens.

We see that the Rathenow Optical Company has registered in Germany a pattern for a lens with spherical and chromatic correction. The specification describes it as symmetrical, or nearly so, and that both halves are formed of a biconvex cemented to a biconcave element. We should like to know wherein the novelty consists. Similar lenses have been used in the past. As proof of this we may refer to the late J. Traill Taylor's book, "The Optics of Photography," wherein, on page 89, the sketch is given of such a combination, which was used by him in conjunction with a set of negative lenses to obtain a range of foci. We do not suppose the Rathenow Optical Company would make such registration without some definite end in view, but at present we fail to see what that end may be.

* * *

Packing Plates.

The material by which sensitive dry-plates are separated from each other is a matter of much moment to the maker, and a variety of methods of packing exist, for all of which there is something to be said on theoretical or practical grounds. Probably nobody is free from action on the emulsion as a surface of that emulsion itself, and the method adopted by some makers of sending out plates with the glass cut through but the unseparated film of emulsion turned over on itself is its own justification. Other innocuous materials are paraffined paper and paper which has soaked in solution of potassium bichromate, washed, exposed to light and again washed and dried. The latter is obviously uncommercial, and the former is expensive. Dr. Miethe now suggests paper saturated with a solution of shellac in borax, which, it is claimed, effectually obviates any chemical action of chlorine, hydrogen peroxides or acids in the paper. The solution of the shellac can be applied with a brush by machinery.

* * *

Packing Roll Films.

Herr Schulze, of Dresden, draws attention in "Appolo" to a very exceptional experience he has had with some roll films sent to him from South America. To preserve them from the damp and the deleterious action of the atmosphere they were sorted into series, packed in tin cases, and soldered down. Upon opening the first case the lid was blown off, with a loud report, across the room, and the roll of films which was enclosed caught fire. This parcel of films was of course spoilt. The explanation seems to be that the celluloid, upon which the emulsion was spread, generated fumes by the heat applied to the box when it was soldered down. These could not escape, and when the box was opened the friction ignited the gas and caused an explosion, because of the smallness of the hole through which the gas escaped into contact with the air. From this it appears that the boxes in which films are packed should not be soldered, and that it is preferable to enclose them in a second outer case, which may then be soldered down in the usual manner.

The New Ortho-The chemical changes which can be run on the cyanin dyes and their compound promise to supply the maker of orthochromatic plates with more sensitizers than he can find time to examine. The latest of the new dyes to appear is one from the Aktien Gesellschaft für Anilin Fabrikation, the firm associated with goods of the trade-mark "Agfa." According to the "Chemiker Zeitung," the dye is produced by a process of mild oxidation. The starting-point is an iodide or other salt of a chinolin in which a methyl group has been introduced into the pyridin nucleus. This, either alone or in admixture with the unaltered compound, is treated with potassium ferricyanide (or persulphate) in alkaline solution. For example, 20 gms. of chinaldin alkyl iodide is dissolved in 500 ccs. of water, and 25 gms. of potassium ferricyanide added with 50 ccs. of strong caustic alkaline solution. The product of the reaction separates in lustrous plates, and is freed from impurities by extraction with ether. This leaves a dye which dissolves in alcohol to a blue colour or in dilute alcohol to a blue-violet. It exhibits an absorption band in the orange, another in the yellow and a third weaker one in the green. It is claimed for the new dye that it sensitises further into the red other cyanin colouring matters.

* * *

A Hint to Advertisers.

An advertisement, which should be of great use to the consumer, is to be found in "Photographische Industrie" for October 26. The Aktien Gesellschaft Aristophot gives graphic curves showing the time of development and the dilution of the developer which should be used for obtaining specified tones with their slow-printing gas-light paper. The tones are given in a column at the side, and the curve which runs obliquely from top to bottom carries a number of perpendiculars which, on the top line, indicate the time of development in minutes. In another table, by the side of the one we have just described, a diagonal line runs from bottom to top and carries perpendiculars indicating of the top line the concentration of the developer, sold by the company, to obtain the tones indicated in the table as already mentioned. These tables are of great simplicity and show at a glance how to obtain the desired colour of image. A given standard of density is of course assumed and the photographer must find out this for himself. There should be little difficulty in regard to it, as a print may be made cut in strips and developed with a solution to which additions of concentrated developer are made according to the table. If the figures, which are given for the standard tone obtained, are then taken as units, the other colours should be obtainable by as simple calculation. Tables of this kind may be made for many purposes in photography, and we think manufacturers would find them very useful as a means of exposition.

* * *

Viewing Stereoscopic Pictures without a Stereoscope.

Some little fillip may be given to this still little adopted but most attractive branch of pure photography by a paper recently read at the Paris Academy of Sciences by M. J. Violle. The accounts to hand are but brief, not to say imperfect; but we learn that a twin lens camera is made use of. Directly in front of the plate M. Violle places a grating ruled with black lines, at the rate of one hundred to the inch. The negative then consists of the two pictures, across each of which is seen a set of fine bands. Prints are taken and mounted in the usual manner, and when they are looked at through a similarly ruled plate it is stated that an image with the usual stereoscopic effect is seen. Failing the possession of fuller in-

formation, it is difficult to see why such relief should be seen under any position of the grating; but no doubt fuller particulars will soon be to hand. If anyone should wish to make the experiment, we do not see why the grating should not be made by photographic reduction to a suitable size of a series of ruled lines on a larger scale. It is scarcely probable that diffraction difficulties would intervene when it is considered how readily process-block prints can be reproduced by photography, showing the dots perfectly on a smaller scale than this. Anyone in possession of a singly-ruled screen for block purposes could try to make such a view without further apparatus being needed, and a single-lens camera used in a suitable manner should be all that is necessary for producing the views.

* * *

The Manipulation of Celluloid.

The many uses to which celluloid is put in photographic work would render any instructions for working it very useful, and quite recently, in the pages of the "Scientific American," full details were given as to how to soften and cement this useful substance. If it be merely required to bend it, it will suffice to place the celluloid in boiling water. If, however, it be steamed at a temperature of about 150 deg. Fahrenheit, it becomes so soft as to be able to be kneaded like dough; and so enable wood, metal, or other material to be embedded in it. When scraped fine and mixed with 90 per cent. of alcohol it assumes the character of a cement, suitable for joining pieces of celluloid together. If it be required to make a solution suitable for varnish, etc., a choice may be made of the following formulæ:—(1) Five grams of celluloid, with sixteen grams each of amyl acetate, acetone, and sulphuric ether; (2) celluloid ten grams, camphor four grams, sulphuric ether, acetone, and amyl acetate thirty grams each; (3) five grams each of celluloid and camphor and fifty of alcohol; (4) five grams celluloid in the same quantity of amyl acetate; (5) five grams celluloid and twenty-five grams each of amyl acetate and acetone. If celluloid be dipped in water just about as hot as the hand can bear, it will soften sufficiently to enable it to be hammered without injury. We may note that we have seen a recommendation to dissolve celluloid in acetone alone to form a varnish: it is perfectly soluble in that menstruum, but, with all the samples of acetone we have tried, the result has been useless, as the varnish so made dries "papery" or white, just like collodion made with pyroxyline from too weak acids.

* * *

A Camera with Quartz Lenses.

As is well known, lenses of glass arrest the ultra-violet rays to a large extent, and for experimental work in that region are almost valueless. Where special investigations are being made in that region quartz lenses become a necessity. Some articles are now appearing in "Nature" describing a series of photographs of stars taken to ascertain their chemistry by temperature, and in last week's issue an interesting illustration is given of a camera fitted with a quartz lens of $2\frac{1}{2}$ in. diameter and 18 in. focal length, in front of which is placed a 2 in. 30 deg. prism of calcite (the well-known Iceland spar is the purest form of calcite). This prism is cut so that its first face is perpendicular to the optic axis of the crystal, and is so arranged that the incident rays are normal to this face; all the rays, therefore, pass through the crystal parallel to the optic axis, and there is consequently no double refraction. By this means it became possible to utilise not only the length of spectrum in the violet, but the relative brightness of the various parts to a different degree than before. The design in using this arrangement, it may here be noted, is found in a quotation from Sir George Stokes, the substance of which has been fully borne out by

more recent work: "When a solid body such as platinum wire, traversed by an electric current, is heated to incandescence we know that as the temperature increases, not only does the radiation of each particular refrangibility absolutely increase, but the proportions of the radiations of the different refrangibilities is changed, the proportion of the higher to the lower increasing with the temperature." Obviously, failing the employment of some such arrangement as just described, no photographs of definite value could be obtained owing to the absorption of the rays of the region under examination by a glass lens. For the same reason a platinum wire is a better source of light of high intensity than the filament of an incandescent electric lamp, as the glass of the bulb would also absorb the violet rays to a large extent.

* * *

British Trade Abroad.

Dealers in photographic apparatus would do well to keep their eye upon "The Board of Trade Journal," which is published weekly at the small price of one penny, for from it they can pick up many hints as to export trade and foreign requirements, which are not likely to reach them from other sources. We learn, for example, from the issue of October 27 that Austria is sending photographic printing paper to Poland, and as this country alone is mentioned, it may be presumed that it has secured the whole of the trade. It is expressly stated by the French Consul-General at Warsaw that all the photographic materials used in Poland come from abroad, mainly from Germany, but the United Kingdom has "a small share in this trade." On another page, with regard to China, it is stated that the only way to secure contracts in that country is by personal canvassing, and the same principles apply in the case of firms wishing to get into touch with Government establishments there, particularly in the case of any articles which require technical knowledge or skill. The Chinese Government prefer to deal direct with manufacturers, local firms having no facilities for bringing such goods to the immediate notice of the authorities. The importance of personal persuasion and judicious advertisement is insisted upon, and incidentally the methods adopted by the sellers of an American sewing machine, and by the representatives of an American tobacco company, are held up as examples of "push" worthy of imitation. The sewing-machine people have their machines working in the open shops in the native suburbs of the Treaty ports, while not long ago the tobacco people made a demonstration up one of the rivers in gaily be-decked house-boats, distributing samples and placards as they went along. This procedure could hardly be recommended for photographic goods, but the lesson may be taken to heart that business will not ensue unless personal energy is expended in the efforts to obtain it.

* * *

The Permanence of Silver Prints.

The keeping quality of so-called gas-light papers is rather important and in these days of struggle for colour effect, the following remarks by Dr. R. E. Liesegang, which have appeared in several German photographic newspapers deserve attention: "Baceland asserts as a result of the examination of the toning action of a mixture of hyposulphite of soda and alum, that such prints are very unstable, when they are produced upon chloride, or chloro-bromide of silver (without an excess of silver nitrate) by over-exposure and a weak developer. According to my experience, this conclusion, which Baceland has deduced from his studies of Velox paper should not be taken as of general application. Emulsions of unripened silver haloids may be made, which give prints of exceptional permanence. The difference can be partly explained

physically. If papers of the Velox kind (Velox, Lenta, St. Lukas, Tula, etc.) are developed with hydroquinone-soda, well restrained with bromide of potassium, the prints will be red to yellow, whereas with metol-hydroquinone or edinol, the colour will be a very deep black. Their strength is not even approximately comparable with that of the black prints. It is evident that the permanence of the former under the same conditions, must be inferior to that of the black. If we are able to increase the strength of the image, the keeping quality must also increase. This is impossible with the papers of the Velox class, which we have named, as the purity of the colour is sacrificed at the same time. The addition of a more active reducer to the developing solution (metol, edinol, etc.) introduces a certain amount of black. On the other hand, prints of pure colour, having great depth, may easily be produced with chloride emulsion papers differing chiefly in their preparation from so-called pan paper. Prints on this paper, which theoretically should be the most unstable, on account of the fineness of the particles of silver, have not shown the slightest change, although they have been kept six years. The exceptional significance the depth of the print has for its permanence, may be inferred from the following. Before gold-toning was used, the photographs produced upon silver by printing out, or physical development, were almost all treated with a freshly acidified fixing bath, for toning purposes. There is some inclination to surprise at the excellent colour of these prints, which were made forty or more years ago, because of the sulphur toning to which they were doubtless submitted. The pictures are from negatives made by the wet collodion process. Prints from negatives of the much thinner gelatino-bromide description could not be treated in this way, without fear of fading within a short time."

CARBON TRANSPARENCIES AND RETICULATION.

At the last meeting of the Croydon Camera Club the subject dealt with was the making of positive transparencies for the subsequent production of enlarged negatives. In the course of his remarks the lecturer pointed out that if the gradations of the original small negative were to be preserved in the enlarged one, then an intervening carbon transparency, he thought, was almost compulsory. There is very little question that, so far as the gradations in the negative are concerned, they are better represented by using a carbon transparency than one by any other process, because here we save the image not only composed of a colour but by varying thicknesses of it—the carbon image being, in fact, a picture in more or less relief according to its gradations. If practical evidence were wanted to prove that carbon transparencies are the best for producing enlarged negatives from, it is supplied by the fact that they are the ones used by all the large firms that make a speciality of enlargements by way of enlarged negatives.

There is one passage in the report we gave last week to which we will call special attention—indeed it is the sole object of this article. The lecturer said that "trouble might, and frequently did, occur with reticulations of the film, but these, as a rule, did not record themselves, provided a daylight enlarging apparatus was employed. With artificial light and a condenser, the opposite frequently prevailed." But many carbon slides are used for the lantern, when, of course, the same conditions obtain as in the enlarging lantern, and it is manifest that what would be fatal in the one case would be equally so, and in an exalted degree, in the other. Now there is no reason

whatever why there should be any reticulation at all, if the process is worked as it should be for the production of transparencies.

As at the present time many will be making carbon transparencies for the lantern, as well as for enlarging from, we shall here give a few practical hints on the working—specially with regard to the avoidance of the trouble which it seems is sometimes met with by novices—and referred to at the Croydon Camera Club. We shall at once assume that our readers are familiar with the working of the carbon process. In the first place the glass to be used must be coated with a substratum of insoluble gelatine, and the omission of this is the basis of all the trouble met with of the reticulation of the film. The best substratum for the purpose is a weak solution of gelatine—say, one ounce to a pint of water—with sufficient of a solution of bichromate of potash added to give just a pale sherry colour. A stock solution of this will keep good, if kept in the dark, for some time, and will only need to be warmed when required for use. It is easy of application; all one has to do is, after the glass is cleaned, to pour a little of it on, drain off, and allow to dry in full daylight. The solution may be applied to the dry glass, or it may be poured over, once or twice, while the plate is still wet. This will perhaps be the least trouble to many. Those who supply carbon printing materials now, we believe, supply plates ready substratumed for the purpose at quite a nominal cost. This will prove a convenience to those who do not like trouble.

After the tissue has been exposed it should be coated with plain collodion. This is a very simple operation. The tissue is slightly bent up round the edges to form a kind of tray, and the collodion flowed over and drained off at one corner and allowed to rest, in the dark of course, until the solvents have evaporated. The picture is then dealt with after the ordinary manner of carbon printing. We are quite aware that successful carbon transparencies are often made without either the substratum or the collodionising, but the fact remains that the larger firms, whose speciality is making carbon transparencies for enlarging from, universally employ this system. If professional workers, with whom time is money, find it worth their while to incur this little extra trouble, it may fairly be assumed that they find it advantageous, in producing the finest work, in their daily practice. With a substratumed plate, and collodionised tissue, even boiling water may be used in the development, if necessary, without the slightest fear of reticulation or frilling at the edges of the picture.

With regard to the exposure for transparencies for enlargement, it may be mentioned that it should be very full—quite three-times that required for paper prints from the same negative will be none too much, even a little more is sometimes better. For lantern slides less will be sufficient—indeed is imperative—say, double or a little less. The appearance of the finished transparency for the two purposes should be quite different. That for enlargement, when laid on white paper, should show no clear glass, except, perhaps, in the supreme lights, and even then will be none the worse for a slight tint or veil if strong and vigorous negatives are desired. Those to be used as lantern slides, when similarly laid on white paper, should have the high lights of quite clear glass, yet with perfect gradation through the half-tones. A suitable transparency for the lantern is useless for enlarging from, while the one suitable for that purpose is worthless for the lantern. It is often recommended to alum carbon transparencies for either purpose, but it should always be avoided, as it is harmful rather than otherwise. Transparencies made on special transparency tissues, containing much colour,

frequently show peculiar surface markings, sometimes called "damp marks." They show only by reflected light, and not at all by transmitted light. They are of no actual moment, but, however, they may be entirely got rid of by simply coating the picture with plain collodion; they then disappear at once.

ON THINGS IN GENERAL.

An interesting article, containing much useful matter and food for thought, that appeared in the last number of this journal over the signature of F. Grenfell Baker is likely to elicit some amount of protest. Mr. Baker writes:—"In photographic materials . . . the purchasing public still demand the best, and that best cannot now be procured from our home markets." Now, as this is written it can only bear the meaning that a better camera is purchasable abroad than is made in this country. Surely he is referring to the cheaper class of instrument, and if so, he may probably be inclined to make a correction in that direction, for, though it is true that a cheap foreign-made camera may out-class an English-built one at the same price, I am sure every one conversant with British workmanship as applied to cameras will agree that it is still the case that a first-class British camera surpasses every camera in the world. It is true that such a camera is likely to be costly; but that is not the point. It is, however, a question whether instruments of the highest character are not priced at such a prohibitive rate as virtually to restrict their sale to small proportions. When, by the aid of plenty of capital, a firm can sink sufficient money in the purchase of machinery for producing the various parts of a camera at a low rate, it is obvious that such manufacturer can turn out a good instrument at a low price; but that is quite a different affair from a question as to "Where are the best cameras made?" No; the reputation built up by a past generation of camera-makers for cameras made in this country is, happily, still deserved by their successors. A camera-maker who, when on his death-bed, insisted upon every instrument turned out of his shops being brought to him and carefully examined before being sent out—and it is not so many years since such a one died in the heart of London—is a fit representative of the highest class of cabinet and optical work which has long been peculiar to this country, and he has his successors.

In the pages of the same number appears a paper by a writer whose articles are always instructive or interesting, which appears to need a little elucidation. Speaking of the cutting prices that are so unfortunately common, he narrates two personal experiences, which may be briefly put as follows: He was offered two guineas for taking a set of a dozen photographs, but declined the commission. In the next paragraph he tells how he offered to take twenty stereo negatives, and print therefrom forty sets of prints (on paper and glass)—that means eighty prints altogether. His action in regard to these prices, is so contradictory that possibly the "Amateur Optician" will explain the discrepant quotations.

There has been a good deal written lately about the quick drying of negatives, especially as regards the use of methylated spirit for the purpose. Now, in careful hands it is incontestable that the process is of great value, though it is liable to a very grave drawback in the form of the production of a white deposit between film and glass, which entirely ruins the negative if not removable. The trouble of the matter is that these markings do not always make their appearance, but if the plate, to expedite the drying, be warmed, and to a point only that is still bearable with the hand, the chances are ten to

one that the deposit will be seen. Those who have met with such a *contretemps* should know that it is not irremediable (though the original efforts for despatch are then frustrated), for if the negative be placed in water for a minute or two the stain will disappear, and will not be seen when the negative is dried in the ordinary fashion. The annoying thing is that the time lost over the operation just occurs when it can be least afforded. I have never yet tried the plan of preceding the "spiriting" by a preliminary bath of formalin solution, though I think it would solve the difficulty, seeing that the negatives could, after the formalin, be dipped in hot water, which would effectually eliminate the last traces of hypo which in all probability are the cause of the trouble. It has been stated that negatives, after the formalin treatment alone, can be dipped in hot water and then dried by the fire in a couple of minutes, a statement that is all nonsense. It takes several couples of minutes before a negative will dry at the fire, and even then there is a risk of spoiling it if made too hot, as, though it may not melt, the outlines of the features and other parts give way in a peculiar manner, the texture becomes coarse, and strangely enough the density increases to a considerable extent.

Some reference was recently made to photographers making "spec pictures" and offering them to their sitters as one way of increasing business. At one time this was largely done by photographers, but one hears less of it now than a few years ago, possibly from its too great resemblance to the "free sitting" system. I know of a case where a photographer tried the plan with a beautiful negative he had of a lady sitter, and he got such a rap over the knuckles as made him vow never to attempt it again. The lady, instead of buying the picture, returned it with such an indignant letter that his ears burned for an hour after.

The abstract of the pamphlet issued by the British Weights and Measures Association forms instructive reading, and advances very grave reasons why the metric system should not be adopted in this country, but their case is weakened by the putting forward the objection that such an immense loss and expense would be brought about by the change. They lose sight of the fact that this objection would apply to any change whatever, oblivious of the fact that if it were admitted, for the sake of argument, that the change were advisable *per se*, such considerations would have to give way. When the present "imperial" system was introduced the same argument applied, but it was adopted and the loss was suffered. Their strong argument is the greater practicability of the present system and the entirely unserviceable nature of the metric system for domestic and general use compared with the imperial system, and its very practicable units and multiples. The crucial point is that the metre is not a useful unit, while the foot and the inch are ideally practicable measures. The only point really worth considering is—Would the change, if made, or would it not, tend to increase our foreign business? For the purposes of everyday life our own system is about as useful as it well could be. The decimal system is, in a sense, a craze for a theoretical perfection of principle, which has been carried out to an almost absurd length. Thus, the Fahrenheit system of thermometer marking is very illogical and the Centigrade, with its freezing point made zero, is excellent in theory; but a Centigrade degree is too large, and the minus degrees are liable to create confusion. Of course, there are minus degrees in the Fahrenheit system, but they do not occur with any considerable frequency, even in cold countries.

I was much struck by the editorial remarks on the "old masters," examples of whose work turn up in such unexpected places. I believe, however, that if any one sells a valuable

work of art—such, for example, as an oil painting—in ignorance of its value, at a very low price, he can recover from the buyer a fair proportion of its value. It is, however, in an opposite direction, very amusing to see the veneration which some worthless daub receives from an ignorant owner. I was once asked to photograph a painting “by Vandyke,” of Tim Bobbin, a well-known Lancashire character, who was born and flourished long after that artist’s death!

As the lantern season is upon us, I may take the opportunity of drawing attention to a detail of practice too often lost sight of, even when once known. Everyone is familiar with the nauseous smell given off by lanterns with an oil illuminant. There are two main causes of the odour, each being remediable. First, the oil ascends the wick by capillary attraction, and if the latter be left above the level of the enclosing metal work, it slowly diffuses out of the wick, and gradually spreads by reason of its thinness, over the whole of the interior. When the lamp is lighted and made hot this oil vapourises, and contaminates the atmosphere of the whole room. The remedy is, when putting the lamp away, to rack the wick well below the level of the metallic part, so as to give no opportunity for the oil to ooze outside; there will then be none to evaporate. The second cause is still simpler. One is so used to turning down the light in a gas burner that there is a natural tendency to do the same thing with the wick of a petroleum oil lamp. But this will not do at all. Such a lamp is constructed to burn with the light turned on full, and the length of chimney, and the amount of air supply, are arranged in accordance. If the light be turned down, the air supply is abnormal, the combustion is imperfect, and gradually there is given off that peculiar penetrating emanation which has such an irritating effect on the organ of smell. When the lamp is of a small simple pattern with a narrow circular chimney, we have seen the air supply lessened by placing a penny part way over the chimney top, thus lessening the draught to an extent that permitted the turning down of the flame.

The remarks upon half-tone blocks also are very timely. This is a branch of business which photographers might well push to advantage. If they would get the subject well up they might often get orders for blocks from their customers, especially if they were able to give the printers a tip or two. But it must be confessed that printers are very like photographers—they know everything. I scarcely ever met a photographer who, when in the course of a friendly conversation I gave a useful tip of my own, did not reply, “Oh, yes, that is a capital plan,” as though he had known it for years. So it is with printers; a man who never had a process block in his fingers will with a light heart undertake to give you a number of perfect prints, though he has no idea of the interdependence of and the need for close selection of ink and paper for the purpose, and has no acquaintance of the mysteries of underlay and overlay as regards such a block, and will, when he has obtained something of a sort from the blocks, no doubt before putting the blocks away, clean the ink off with the same caustic alkali that he uses for stereos and type! I know those printers.

The P.P.A. deserve every praise for the labour they have expended over the excellent syllabus of questions, etc., as to competence of assistants—a burning question to many masters who have been at times almost beside themselves in consequence of the employment of unskilled hands, whose demands and effrontery have been in inverse ratio to their knowledge and experience. The suggestion that “constructive criticism” is the kind that is wanted is neat. It is so very easy to pull a

thing to pieces; it is so much more difficult to mend than to end, to plagiarise a well-known political saying. One little thing occurred to me. When an employer is asked about an assistant’s optical knowledge, one immediately thinks of some photographers one has known who know as much about optics and the powers of a lens as a hippopotamus does of the Greek digamma. What is the value of their opinion to an assistant who knows a good deal more about “that rot,” as it would be termed, than they do themselves? All the same, my individual thanks are offered to the Committee of the P.P.A. for the labour they have already given to what, I am afraid, will prove an utterly thankless task. Such is human nature!

FREE LANCE.

THE SCOTTISH PHOTOGRAPHIC FEDERATION.

SCOTLAND has been known but slightly to the photographic world as the residence of good photographers. Although such names as J. Craig Annan, William Crooke, Archibald Cochrane, J. M. Whitehead, and several others are household words in photographic circles, still these are rather considered as examples of the *rara avis* than as inherent parts of the body photographic in Scotland. The general body of Scottish photographers and the class of work executed by them were comparatively unknown to British photographers until the Scottish National Salon, held at Perth this year, burst on the photographic world, and proclaimed the fact that Scotland was an entity to be considered, and proved that, relying wholly on native talent, it was possible to hold an exhibition that was creditable to the nation, and quite fit to rank alongside the established London shows.

The Scottish Photographic Federation, the body to which the National Salon is due, is a plant of recent growth, strong and healthy. The support accorded to it is such that it can now without any undue assumption, claim to be the representative photographic body in Scotland. A body that can attain this distinction in so short a time may well merit the attention of the readers of the *BRITISH JOURNAL*, and this article is written with the view of telling the story of its birth and growth, with some notes on its aims and objects.

The movement really originated in a proposal, made by the Brechin Society, to form a local federation—confined to the societies in North-Eastern Scotland. The Dundee and East of Scotland Association, as the senior society in the district, at the request of their Brechin confrères, convened a meeting in Dundee to consider the project. At that meeting it was agreed, on the motion of the Blairgowrie and District delegates, to give the Scottish societies an opportunity of making the movement national, and Mr. John B. MacLachlan, Blairgowrie, was instructed to make the initial arrangements for a meeting of representatives of the Scottish photographic societies at Perth.

All the societies of which the *pro tem.* secretary had any knowledge were written to, with the result that on January 17, 1903, twenty-seven delegates from fourteen societies in different parts of Scotland met at Perth, under the chairmanship of Mr. Henry Coates, President of the Photographic Section of the Perthshire Society of Natural Science. After a free interchange of opinion, Mr. James M. Maclean, secretary of the Glasgow Southern Photographic Association, moved: “That this meeting is of opinion that a Federation of Scottish Photographic Societies should be instituted, and hereby resolves to do so.” Mr. Vanessa C. Baird, secretary of the Dundee and East of Scotland Photographic Association, seconded. Although no amendment was proposed, the chairman decided to take a vote on the proposal, when twenty-one delegates voted in favour of the motion; six declined to vote, but some of these explained that they could not vote before consulting their societies. The motion then became the finding of the meeting.

Messrs. Maclachlan, Blairgowrie and District; Kirk, Brechin; Horn, Glasgow Southern; and Burns, Edinburgh (the latter to be elected if his council permits), were appointed to prepare draft rules, and send them to the societies for consideration before the next meeting. The delegates were then entertained to tea by the chairman. At that function Sir Robert Pullar attended, and congratulated them on the initiation of a work that was bound to be beneficial to Scotland.

At the next meeting, held at Perth on March 21, the draft rules were considered, and, after several amendments had been made—the result of a thorough discussion—were approved of. It was intimated that sixteen societies had definitely decided to join the Federation, which was officially baptised "The Scottish Photographic Federation." Office-bearers were elected, the next annual meeting was arranged for, and the work of the Federation really set in motion.

At the first meeting of Council, held on May 2, it was agreed to have a lantern slide competition open to the federated societies and associates, and to prevent any drain on the funds of the Federation at this early stage of the proceedings, the president, Mr. Coates, Messrs. Eadie (Monklands), Stewart (Kirkcaldy), and Macdougald (Dundee and East of Scotland) promised to give the prizes. A list of judges for the exhibitions and competitions of federated societies was drawn up, and the secretary instructed to write and ask their consent. It was also agreed to promote an exhibition at Perth, opening on the day of the annual general meeting, and a committee was appointed to make the necessary arrangements. At this meeting the first non-society associate was elected. It will be seen from the amount of business done at this meeting that the Council was thoroughly in earnest, and determined to so set to work that the Federation would justify its existence, and become a real power in the betterment of Scottish photography.

At the next meeting of Council the secretary reported as to the response of the societies to the request of the Council for lecturers, etc., available for federated societies. Considering the short notice given, the response was a hearty one, and resulted in the issue of a list comprising thirty-three items. The exhibition germ had now matured into a National Photographic Salon, confined to Scots at home and abroad—no entry fees and no prizes.

The lantern slide competition was well supported, 268 slides being entered. Messrs. Keighley, Bingley, and Clough, of the Yorkshire Union, kindly acted as judges. The president's prize—a solid silver shield—for the society competition, was won by Glasgow Eastern Amateur Association; Dundee and East of Scotland being second, and Paisley third. The associate competition resulted in Mr. W. S. Crocket, of the Glasgow Eastern, being first; Mr. Archibald Campbell, Dundee and East of Scotland, second and third, but as the rules precluded one competitor gaining two awards, Mr. John B. Maclachlan, Blairgowrie and District, gained third prize. The prize slides were formed into a circulating set, and proved a valued feature on the syllabuses of many of the federated societies.

The first Scottish National Salon had about 350 entries; from these the Council of the Federation—officiating as the selection committee—selected 207 pictures for exhibition. These were tastefully displayed on a specially arranged background, showing a frieze with a design embodying the Scottish lion rampant and the Scots thistle, in the Art Gallery of the Sandeman Free Library, Perth. Mr. Percy Lewis, Bristol, sent a characteristic exhibit of his work, as representing England, while a happy thought of the committee included in the Salon an admirable exhibit of the work of D. O. Hill, that great exponent of artistic photography, in a series of prints kindly lent by Messrs. J. Craig Annan, Glasgow; and Andrew Elliott, Edinburgh.

Mr. Coates, president of the Federation, opened the Salon in

presence of a large number of associates, and also a representative body of the municipal and social luminaries of Perth.

At the annual meeting, which was held afterwards, more work was initiated. It was agreed to have an excursion to Callander, and it might be remarked, right here, that that excursion was duly held on June 11, when between fifty and sixty associates, blessed with splendid weather, enjoyed the magnificent scenery around that favourite summer resort, as well as the cheerful good-fellowship that prevailed.

A portfolio was also initiated, and at the time of writing gives every promise of being a success.

A year-book was another innovation, and "The Blue Book," as it was decided to call it, has met with a most hearty reception. "The Blue Book," besides rules, etc., contains a list of "experts" willing to help associates in any difficulty in the various phases of photography of which they have made a special study. It also contains a list of exhibitions promoted by federated societies, and in that list it may be noted that the movement initiated in the beginning of this year, of having classes confined to associates, has been heartily taken up, quite a number of societies having made that a feature of their exhibitions. There is also a gazetteer, which it is to be hoped will be extended in next issue, giving brief details of different centres, dark rooms, and "reporters." These "reporters" are a decidedly useful novelty; their mission is to give full information respecting the districts under which their names appear to any intending visitor.

It was agreed to hold the next Salon in Glasgow. The 1905 Salon is to be held in the Galleries of the Royal Art Institute in Glasgow, opening on January 14. The selection of pictures has been delegated to a board of jurors—Messrs. Archibald Cochrane, Barrhead; J. Craig Annan, Glasgow; and Wm. Crooke, Edinburgh—instead of being performed, as on the previous occasion, by the Council. As far as can be judged at present, there is every prospect of the Glasgow Salon rivalling the success of the first one at Perth. The Salon committee are displaying praiseworthy energy in their work. They have already secured for the special "foreign" exhibits promises of representative collections from Mr. Alexander Keighley, Keighley, Yorks, and Mr. Alfred Enke, Stuttgart. It might here be mentioned, *inter alia*, that one of the features of the Salon is to invite an exhibit from one or more prominent men outwith Scotland, so that an opportunity may be thus given of comparing home work with the best from other countries. The home workers, it is needless to say, will be fully represented. The Lord Provost of Glasgow, Sir John Ure Primrose, Bart., himself an enthusiastic and successful photographer, has agreed to perform the opening ceremony.

Since May of this year, with the view of keeping the associates—widely scattered throughout Scotland—fully informed of the work of the Federation, the Council has published a monthly journal known as "The Secretary's Letter." The list of judges, lecturers, etc., has also this year been much extended, the present list comprising seventy-six entries.

The sixteen societies which formed the Federation at its institution had at the close of its first year's work grown to twenty-three; that number has again expanded, until at the present moment the Federation consists of thirty-three societies, all banded together to work for the good of Scottish photography and Scottish photographers.

This all too brief narration tends to prove that the Federation was wanted to join together the scattered forces of photography in Scotland, and the success attending its efforts proves that that labour has not been in vain.

Already there are visions of further accessions to its ranks in 1905, and it is to be hoped that the time is not far distant when all Scottish societies and photographers will join the Federation as a matter of course.

ALLAN BLAIR.

THE TESTING OF ORTHOCHROMATIC PLATES.

III.

I AGAIN take the liberty to quote Dr. Eder, and he says, in his "Spectralanalytische Studien über Photographischen Dreifarbendruck," read in July, 1902: "The spectrum experiments for the purpose of three-colour photography must be supplemented by tests on pigmentary colours. The ratio between the distribution of the luminosity of the solar spectrum and the light reflected from pigments has been determined for special cases, and several statements have been made. Yellow, at the Fraunhofer line D, in the solar spectrum has been estimated by various observers as from 9 to 31 times optically brighter than the spectrum blue at F $\frac{2}{3}$ G, and from 21 to 87 times brighter than the darker spectrum blue at G, whilst pigmentary yellow appears from 6 to 14 times brighter than blue; and yellow in the spectrum is from 19 to 40 times brighter than red between B and C, whilst pigments it appears, however, only from 3 to 7 times brighter. Again, as the relative distribution of the luminosity differs in the diffraction and prismatic spectra, the result is that all these experiments cannot give results which are immediately comparable as to the photographic value of colours."

Having thus far simply found fault, you may well ask whether I have not some remedy for the existing state of things to suggest. And I have. Now, you may well ask why, if this is the case, I do not show you results proving that the method is satisfactory. My only answer is that, whilst I early recognised what I thought was a satisfactory method, I could find no light which was, in the first place, approximately daylight and constant, and, secondly, that I have lived long enough to learn that the first duty of man is to earn rent for his landlord; his next duty is to earn boots and shoes and food for those dependent upon him; when he has done this and found a crust for himself, he can then find money for experimental work which does not bring in any of the above results. So far, I am glad to say, I have been able to discharge the first three duties, but I have not been able to find the extra pence for experimental work — or, rather, the necessary apparatus.

If Sir Wm. Abney's admirable plan of instituting an R.P.S. laboratory were carried through, such work as I have outlined could be done by private individuals and amateurs.

The chief difficulty I met with was the constant light source of the same colour composition as daylight; but, since the first part of my paper was drafted, Messrs. Kenneth Mees and S. G. Sheppard read a paper before the R.P.S., in which they stated that they had adopted a special form of acetylene generator as a light source, and described also an arrangement by which practically daylight is obtained. Their actual words are: "In working at commercial speed-finding, the box is fitted with a light blue screen, so that the spectral composition of the acetylene light used is reduced to be almost exactly the same as daylight, in order that orthochromatic plates may give numbers which, in regard to ordinary plates, represent fairly their behaviour to midday cloud light. Most orthochromatic plates give much too high speed numbers when these numbers are found in the ordinary way."

Again, during the discussion Mr. Mees stated that, "with regard to the standard light, as he was contemplating the sensitometer and its application to commercial work, he found it necessary to get rid of the difficulty caused by the fact that, it being impossible to use daylight for sensitometric purposes, the spectral composition of the light used for testing differed from that used in practice, and, consequently, the relative speeds of ordinary and colour-sensitive plates would be quite different in practice to those measured in the sensitometer."

Given this light, all that I would suggest is Dr. Eder's method of determining the relative blue and yellow sensitiveness of a

plate. The principle involved is merely the use of a sensitometric system such as Hurter and Driffield, and the division of the light by fluid cells into blue and yellow. This is the rough idea.

Dr. Eder uses a sensitometric method analogous to H. and D., and between his light source and rotating sector he places first a cell of known internal measurement, containing first water. The speed of a plate is then read, and this determines the absorption—or, rather, speed-reducing power—of the cell and solvent. Then the same cell—and this is important—is filled with ammoniacal solution of sulphate of copper, made by dissolving 20 g. of pure crystallised cupric sulphate in some water, adding sufficient solution of ammonia to make a clear solution, and making the total bulk up to 1,000 c.c.

The absorption of this filter is shown in the following diagram, and, as you will see, it extends from the red to 6½ F. In fact,

Fig. 2.

this blue filter practically passes nothing but blue and violet; what little blue-green passes is so weak as to exert but a negligible action.

Having thus determined what I call the ordinary or non-colour sensitiveness of a plate, we want to determine its ortho property, and this is done by filling the same cell, and proceeding in the same way, with a solution of 40 g. of neutral potassium

Fig. 3.

chromate in sufficient water to make 1,000 c.c. The absorption of this is shown in the accompanying diagram, and it will be seen that it extends nearly to F, whilst above is the curve of the sensitiveness of a normal ortho plate.

Thus far my suggestions have been merely those of Dr. Eder, but I would go further than he does, and I would again fill the cell with a solution of Tolan red, in the proportion of 1 : 4,000,

Fig. 4.

which absorbs all the more refrangible rays up to the D line, passing only orange and red, and I would again determine the H. and D. speed of the plate.

The result of an examination of the commercial plates conducted on these lines would be that we should know, not only the speed of an ortho plate compared to an ordinary, but we should also know its relative ortho speed in the same terms, and, if it possessed any red sensitiveness, we should know this in the same way.

A tabular statement of this kind drawn up by an independent worker would enable the user of an ortho plate to learn more than all the literature that has yet been published on the subject, because it would give reliable data. It would give also, not only the relative speeds to blue and yellow, but it would determine the characteristic curve of the plate when used as an ordinary and as an ortho plate, and it would enable one to just a yellow screen so as to obtain any given effect.

I hope that no one will misunderstand the purpose of my paper. It is not to decry the spectrum as an authority, but merely as a standard when camera exposures are subsequently made on the object. Considering that for over twelve years I have been playing with the spectrum, there is no one more likely to recognize its value as the first tribunal; and, if I may borrow an everyday simile, the spectrum is the magisterial trial which decides that there is a possible case, but the final tribunal must be Quarter Sessions in the shape of practical work.

In chemistry, when a suspected substance is sought for, the most delicate test is applied. This must be the case in photography, but having, by the extremely delicate test of the spectrum, found that a dye does orthochromatise, we must test its practical value, and, if it does not answer to this, then we can reject it or modify our opinion.

It is curious that a discussion should have arisen in "Photography" on this very subject within the last few weeks. I do not intend to summarise all that has been said *pro* and *con*, but it showed that there is a strong feeling in favour of a reliable system of ortho plate-testing, and against the hyperbolic claims made for them.

I would ask you to consider that until we get some system of orthochromatic plate-testing, which will give us definite, reliable data from a particular standpoint, and that a commonly accepted one, any rhapsodies in defence of or against the ortho plate from the point of view of "pictorial effect" are simply individual mental impressions. Colour is a non-existent substance; it is not the property of a substance, but the function of our eyes, and hence differs to an extent, possibly almost unappreciable, with each observer.

There will always be trouble in connection with this subject because it is complicated by the question of colour contrast and visual luminosity, the two being by no means synonymous. What I mean is, that whilst a particular colour may have a given visual luminosity under certain conditions, under others it may seem to be intensified or reduced. For instance, take the orange of a given brightness, and, in juxtaposition with a yellow of equal luminosity, it will look dull; but place it against its complementary blue-green of equal luminosity, and it looks far more vivid. This, if right, raises an important question as to whether we can ever render colour correctly, but it means considerable argument, more work, and experiments to prove the right or wrong. In any case, we cannot be worse off by having a commonly accepted and fairly scientific system of ortho plate speed measurement, and one which shall replace the glorious haphazard method of to-day.

I would also ask you to remember that, from some considerable experience in plate-using, I personally would never use anything else than an ortho plate. There is a difference, but at times a very subtle one, and I am convinced, to use the words of an old and respected member of the L. and P., that an ortho plate will do all that an ordinary will, and at times a great deal more.

I have no complaint against the ortho plate; it is merely against the extravagant statements made in its favour, and against the utterly unscientific and totally misleading method of testing it at present in vogue, that my notes to-night are directed.

Now, Mr. Chairman and gentlemen, I have come to the conclusion of my notes. I know they are incomplete. They are, at least, honest, and I make this claim in the face of the

fact that I am commercially interested in the manufacture of ortho plates; but, if anyone can find that I have put a bit of lead in the scale, I am here to be shot at. If I have done nothing else, I hope I have given you a topic for discussion for one evening, and, at least, not bored you.

E. J. WALL, F.R.P.S.

MINIATURES.

RECENTLY—or say for a little over twelve months—there has been a greatly increased demand on the part of the public for photographic miniatures, varying from the humble P.O.P. prints to expensive coloured work on ivory. Whilst this rush is on the question presents itself, "Are photographers making the most of what almost amounts to a boom?" We think in many cases the answer is no, and not from the professional underrating the profit to be made in this branch, but chiefly from the lack of business initiative from which the profession seems so prone to suffer. This should not be the case, for not only is the trade likely to be diverted from your hands if you are not wide awake, but the craze is spoiling trade in larger and more important work.

The miniature proper is, or should be, a complete picture in itself, and on account of its size, which allows the eye to take in every detail at once, the demands it makes on the photographer's skill is more insistent than that felt when making larger work. This view of a miniature—a thing apart—is not, however, the view taken by many professionals, and we will glance at a few of the many applications of portraits which are classed generally under the heading of miniatures.

Apart from the usual portrait known as a miniature, which may be used for table or be large enough for wall decoration and is also finished for keeping in a pocket case, they may be small enough to be used for the adornment of charms, brooches, pendants, and watch cases, etc. The actual process is of no great moment so long as it is capable of fulfilling the task imposed upon it. Frequently enough the so-called miniature, far from being a portrait specially taken with a view to this use, and with lines and masses arranged to compose well in the space it is required to fill, it is merely a copy of a larger photograph. In this case of course the photographer's hands are tied, and the best must be done with the original one happens to have. The actual copying is of course as usual, and being to a smaller size so much care is not required to prevent the grain of the original paper support showing, but it is not advisable to use a very small stop. This class of work, however, does not bring much grist to the mill, though unfortunately it is the more usual way of securing a small photograph.

The miniature proper is at present occupying the minds of the better photographers, and if you have the requisite skill and artistic taste you cannot do better than make a speciality of this line. Of course, on account of the extra skill required, a corresponding price should be charged. They may be finished as with an ordinary print or by any process according to price charged, but the photographer will be wise to use only the best processes for this work. Carbon on paper, ivory, or opal, smooth platinum-type, or sepia ditto, are the best for the work. The albumen process, on account of its rendering of the fine details so necessary for these pictures, is very suitable, and as we know from the specimens found in old albums, if properly made albumen prints are fairly permanent. These miniatures may be framed in the usual rims which are supplied in many patterns or may be mounted in the usual way. In this case the mount should be large and of very delicate lines, which preferably harmonise with colours of the print. The modern paper mounts give a very refined appearance to these miniatures, especially the vellums for sepia prints, which is altogether in keeping with the pictures.

To revert to the miniatures for charms, carbons on ivory are very effective. Ceramic enamels sell well and their appearance is especially suitable for charms and pendants. Although somewhat expensive in good businesses they go well. Although not such a good line as at one time, coloured miniatures on ivory are feeling the increased business now being done in small work. They should, however, be painted by a good firm if they are to be a credit to your establishment. No one wants to see a return of the crude efforts of some ten years or so ago. For this reason the tinted photographs, that is a water-colour wash on a bromide or platinum print, very different, by the way, from the coloured ivory with carbon base, should be eschewed or only accepted when very exceptionally done. The new semi-tints, i.e., usually sepia plat., with flesh and dress tinted, are much better, and with a deep rich background make fine pictures.

The small reduced photographs for personal adornment are of course made by nearly all photographers, but we are sure, and would impress it upon pushing business men, that there is a future before photo-miniatures if they are made by a man with artistic perception who has enough knowledge to fix into a small space the necessary essentials for a successful miniature. You may think they differ but slightly from an ordinary photograph, but a man who can make a perfect miniature must be very near the top of the professional tree.

To those who are thinking of taking up this line a few words on what we think constitutes a miniature, and the difficulties of its production, may be of use. As before mentioned, the difficulties arise chiefly from the fact that the picture is so small that the eye takes in every detail, and therefore sees the beauties and defects at once, differing from other photographic work in that one does not miss the defects on account of the good points. Therefore there must be no or at least very few and minor defects. This means that every line must be correct, detail must be delicate and present in full force, modelling, massing of light and shade both of figure and background must all be perfect and in harmony with the subject. All this you must admit is a tall order, and none but the cleverest can undertake the work with success. But is it not worth striving and working for? The trouble, care, and study which will be necessary cannot but improve your ordinary work, and surely in these times of keen competition this is heartily to be desired.

W. FOSTER BRIGHAM.

THE ST. LOUIS EXHIBITION AWARDS.

The following is a list of the awards in Group 16.—Photography.—Grand Prize.—(1) Captain Sir W. de W. Abney, K.C.B., F.R.S., (2) Walter Bennington, (3) A. Horsley Hinton, (4) Alex. Keighley, (5) the Royal Observatory, Greenwich, (6) the Royal Photographic Society, (7) the Solar Physics Observatory, (8) Sir Benjamin Stone, M.P. Gold Medal.—Ernest R. Ashton, Arthur C. Banfield, B. H. Bentley, Carine Cadby, Archibald Cochrane, Dr. Copeland, Reginald Craigie, the Cretan Exploration Fund, George Davison, Frederick H. Evans, W. T. Greatbatch, Karl Greger, Professor W. N. Hartley, Frederick Hollyer, Charles Job, the Geological Photographs Committee of the British Association, G. Lindsay Johnson, M.D., F.R.C.S., R. B. Lodge, Charles Moss, A. J. Newton, Newton and Co., Albert Norman, L.R.C.P., L.R.C.S., Dr. T. K. Rose, Edgar Senior, the Rev. Walter S. J. Sidgreaves, Dr. E. J. Spitta, J. E. Stead, F.R.S., the Survey of India, W. E. Wilson. Silver Medal.—Harold Baker, Mrs. G. A. Barton, David Blount, Will Cadby, J. H. Gear, F.R.P.S., Miss Constance Ellis, Charles F. Grindrod, the Viscount Maitland, F. J. Mortimer, J. C. S. Mummery, Ralph W. Robinson, Frank M. Sutcliffe, W. Thomas, T. Wright, Tempest Anderson, M.D., T. E. Freshwater, F.R.M.S., Douglas English, Dr. Vaughan

Cornish, F. W. Harbord and Alfred Campion, Captain D. Wile Barker. Bronze Medal.—John Henry Anderson, W. Smed Aston, Arthur Burchett, Eustace Calland, Lieutenant-Colonel J. Gale, John H. Gash, Bernard Moore, Ward Muir, William Rawlings, J. Cruwys Richards, James A. Sinclair, John Warburg, J. B. Wellington, Bagot Molesworth, F.R.P., J. W. Gifford, Great Eastern Railway, J. Hort Player, H. C. Carpenter, E. F. Law, the Photolinol Company, J. C. Coultas.

LUNAR PHOTOGRAPHY.

[Presidential Address to the British Astronomical Association.]

THE subject I have chosen for my address this afternoon is the history of lunar photography, to which I have added a few words the uses to which the photographs may be put. The discovery of the Daguerreotype process was announced in January, 1839, and the details were made public in the following August. In the following March Dr. J. W. Draper succeeded in obtaining a series of Daguerreotypes about an inch in diameter showing the principal formations. In 1850 W. C. Bond, with the assistance of Mr. J. A. Whipple, obtained a series of photographs about 2 in. in diameter with the Harvard 15 in. Merz refractor. These were shown at the Great Exhibition of 1851 and elsewhere, and a prize medal was awarded Mr. Whipple. The use of collodion was suggested by Legay in 1839 and from that time until 1876 the wet-plate process was almost exclusively employed. The first to apply it successfully in England to photographing the moon was Mr. Dancer, of Manchester. It was followed by Professor Phillips and Mr. Bates in 1853. The next year Dr. Edwardes, with the assistance of Mr. Forrest, and under the direction of Mr. Hartnup, commenced a series of experiments with the 8 in. refractor of the Liverpool Observatory. These were continued during the two following years by Mr. (now Sir William) Crookes. Several other English astronomers took up the work; but the most successful of all was Mr. De la Rue, who, as early as 1839, had obtained good collodion photographs. In 1857 Mr. De la Rue removed his telescope from Canonbury, where his first attempts had been made, to Cranford, and, having furnished it with clockwork, was able to secure much better results. Many enlargements from his negatives are still in existence, whilst the telescope itself and number of his negatives are preserved in the University Observatory, Oxford. All who had photographed with refractors had noticed that the best focus for the actinic rays was further from the object-glass than the visual focus; but it was Lewis Rutherford who constructed the first object-glass specially corrected for these rays. Rutherford commenced his experiments in 1858, and, although his results compared well with the best obtained previously, they were not good enough to satisfy him, and he speedily convinced himself that the fault lay in the correction for achromatism. He tried first the effect on a correcting-lens before the object-glass, then separated the two lenses of a visual object-glass. Neither of the methods giving satisfactory results, he experimented with a reflector, but this was soon abandoned in consequence of the tremors of the city and the rapid tarnishing of the mirror. In 1863 he undertook the construction of a photographic object-glass; this was completed by December, 1864, and in the following March he secured two photographs of the moon, which were at once seen to be far superior to anything previously accomplished. The amount of detail shown would cause them to take high rank even amongst photographs of the present day. The work of Henry Draper, so far as it applies to lunar photography, was almost contemporary with that of Rutherford. In the course of a visit to Europe in 1858 he was so much struck with Lord Rosse's 6 ft. reflector that, on his return to New York, he set to work in the intervals of his professional labour, to construct a mirror for himself. In the course of this work he ground and polished no fewer than one hundred mirrors of various sizes, the one finally selected was of great excellence, and 15½ in. in diameter. With this he obtained photographs superior to any other except, perhaps, those of Rutherford—some would not admit even this exception. From 1869 to 1871 he was occupied in the construction of a 28 in. mirror, with which a few very fine photographs of the moon were obtained; but from this time Draper devoted himself chiefly to the work of photographing stellar spectra, with which

this name will always be associated. In 1870 good photographs were taken by Mr. Ellery with the Melbourne 4 ft. reflector; Dr. Gould, at Condob, and Dr. Common, at Ealing, also got very fine pictures; but it is impossible to notice all who had done good work in this direction, and attention must be confined to those observatories which have given special attention to lunar photography, and have done most to make their work accessible to astronomers in general. Foremost among these is the Lick Observatory, which in 1896 commenced the publication of a photographic atlas of the moon consisting of enlargements from negatives taken with the 36 in. refractor between August, 1895, and April, 1897. These were made on a scale of 38.36 in. to the moon's diameter, this being the scale of Beer and Midler's map. Nineteen sheets have appeared, and the atlas is a most convenient one; but it is so long since the last sheet was issued that there is reason to fear that their publication has been stopped. The next great observatory to take up the work was that of Paris, where for the last ten years the great equatorial coudé has, under the direction of Messrs. Loewy and Puiseux, been almost entirely devoted to it. Many hundreds of negatives have been taken, but only the best are selected for enlargement. These are reproduced by heliogravure on a scale which varies from 1.19m. to 2.72m. to the moon's diameter. The sheets are large for frequent use, but are of great value for occasional reference. A much cheaper edition on a scale two-fifths that of the original is being published by the Société Astronomique de Belge, and forms the most convenient atlas for frequent use with which I am acquainted. A large number of photographs had been taken at Harvard with the 13 in. Boyden telescope; but whereas those taken at Lick and those taken with the equatorial coudé have been taken in the primary focus of the telescope at Harvard, it is usual to photograph through a 2 in. positive eye-piece, which enlarges the image about four times. This method has also been adopted by MM. Paul and Prosper Henry at Paris. With regard to the relative advantages of the two methods, it may be noted that to obtain a good negative it is desirable that the exposure be as short as possible, in order to diminish the defects arising from atmospheric disturbance and from imperfect following; this condition is secured by placing the plate in the primary focus of the object-glass where the light is most intense. But the image here is small, and must be considerably enlarged to bring out as much detail as possible in a reproduction. This enlargement is carried to such a scale that the grain of the plate becomes a prominent feature, and this is the more serious because, in order to render the time of exposure as short as possible, it is necessary to use the most rapid plates, and these have invariably a large grain—a grain so large as to be comparable with the images of the smallest objects the telescope will show. If the image is enlarged before it falls upon the sensitive plate the grain of the plate becomes much less conspicuous, and small objects can be more certainly detected; but a longer exposure is necessary, and the difficulty of obtaining a good negative is increased. An effort to overcome the difficulties has been made at Harvard by increasing the focal length of the object-glass. A telescope with a 12 in. photographic object-glass of 135 ft. 4 in. focal length was set up by Professor W. H. Pickering at Mandeville, Jamaica, and a set of negatives obtained with it in accordance with a scheme admirably conceived for producing a complete photographic atlas of the moon. Unfortunately, owing to various causes, the object-glass had to be stopped down to 6 in. and the time of exposure greatly increased. The plates are published in Vol. II. of the Harvard Annals and in Professor W. H. Pickering's book on the moon; but in consequence, probably, of atmospheric disturbance definition leaves much to be desired. Up to the present time there can be little doubt that the best results have been obtained by exposing the plate in the principal focus, and this, too, is the plan adopted by Mr. Ritchey, whose marvellous photographs have yet to be noticed. These have been taken with the 40 in. visual object-glass and a yellow colour screen. Mr. Ritchey watches the images of the moon by means of a totally reflecting prism suspended in front of the exposing shutter. When an instant of good definition is noted the prism is removed and the exposure made. In this way he has been able to secure much finer detail than has ever been photographed before. I have detected on one such of Ritchey's negatives a small crater on the floor of Ptolemaeus so difficult that, although the region has been under the special observation of the members of the Lunar Section for the last thirteen years, no one, so far as I am aware, had previously recorded it. Since seeing it on the negative, I have been just able to see it, and

to measure its position with a 7 in. reflector; but I should probably have overlooked it had I not previously known of its existence. An illustration of one of the uses to which photographs of the moon may be put is to be found in a recently issued number of the Smithsonian contributions to "Knowledge," in which Professor N. S. Shaler, of Harvard, gives "A Comparison of the Features of the Earth and the Moon." Professor Shaler commenced his studies of the moon in 1867 with the Merz 15 in. refractor of the Harvard Observatory; but since 1872 they have been almost entirely pursued by means of photographs, which he has found more convenient and more serviceable than the opportunities afforded by even such an instrument as the Harvard Merz. Many astronomers have endeavoured to form a consistent theory to account for the peculiar features presented by our satellite; but it is rarely that the question has been approached by an expert geologist, and this alone would afford good reason for welcoming such a work by one so eminent as Professor Shaler. Professor Shaler believes that the ring mountains are the result of volcanic action of a much less violent type than terrestrial eruptions: there were no explosions, but simply a quiet upwelling of lava of a very viscid character. The maria he believes were caused by the impact of large bolides, perhaps five or ten miles in diameter. He will not allow the possibility of any present volcanic action on the moon, nor of the existence of even the lowest forms of organic life. He seems to be unacquainted with the reasons on which selenographers have based their belief that the moon still has some slight atmosphere, and though his book will well repay a careful study, it is probable that selenographers will not agree with all his conclusions. He himself admits that many of them are debatable. Another use which may be made of photographs is for the determination of the selenographic positions of a number of well-marked points to serve as bases, either for the construction of a large-scale accurate map, or for the minute observation of selected portions which it is much to be desired that all who wish to advance our knowledge of lunar topography should make, and which cannot fail to yield a rich harvest of results. Dr. Weinek, of Prague, has shown how the photographs may be used for measuring the heights of mountains above the level on which they stand, and when a number of measures have been made of the same point on different photographs it may be possible to deduce its absolute altitude above or below some "mean sphere." By combining a number of such absolute altitudes it becomes possible to obtain an idea of the figure of the moon. And, again, by measuring the positions of a few points on a great number of plates, spread over at least two or three years, it may be possible to get a new determination of the moon's physical libration. All this is much more than could be accomplished by any one astronomer, but it is not too much for an association. Is it too much to hope that more members of the B.A.A. may be induced to take up some part of it? S. A. SAUNDERS, M.A., F.R.A.S.

A NOVEL METHOD OF PUTTING CLOUDS INTO LANTERN SLIDES.

THE making of lantern slides, fascinating work though it be, has its troublesome and worrying side. One of these is putting in clouds. My method, I think, has the charm of novelty, and I would like to give readers of the "B. J." the benefit of it, if I may. Lantern slides, as we all know (or should know), with blank white skies, are an eyesore, not to be tolerated for a moment by good workers; nothing looks so bad upon the screen. I will endeavour, to the best of my ability, to describe my method; fairly simple if one does it properly, but therein lies the cause of the worry previously alluded to. It is so painfully easy to do it improperly! Presuming the landscape of the slide is made to your satisfaction—which, with a good worker, is seldom the case—the next "item on the programme" is the selection of a suitable cloud negative (a quarter-plate one). Care must be taken to observe that this, when forming the cover glass, is lighted the same way as the landscape, that is to say, from the same direction. For instance, should the cloud negative be lighted from the right, it will, when bound to the slide, be lighted from the left, and vice versa. Your mind being easy on this score, place the quarter-plate cloud negative in contact with the already-made landscape slide, and observe which portion of it comes most appropriately into the

sky portion of the landscape slide, bearing in mind the warning previously given as to the lighting. Now, with a small paint brush, charged with water colour (red for choice) paint upon the back of the cloud negative the outline of the landscape lantern-plate seen through it. This is for the purpose of indicating the place to be occupied by a previously unexposed lantern plate, to afterwards form the cloud cover glass. The next thing to do is to observe if the cloud overlaps the landscape. Should it do so, then make another line in paint across the back of the cloud negative to indicate that that portion need receive no exposure; in fact, the portion below this line is eventually covered up to prevent light acting upon it. Now take a half-plate printing frame, with glass in it. The reason a half-plate is used is this, it enables the cloud negative to be moved about, so as to use any portion of the cloud. Take an unexposed lantern plate and (in the dark room, of course) place it film downwards, as in printing, within the limits of the painted lines (alluded to above) and put the back of the printing frame on in the usual way. You are now ready for the exposure—not forgetting to cover up that portion below what I had better describe as the "landscape line" painted on your cloud negative, and also mentioned above. Lay the printing frame upon a table, face downwards, and expose. Clouds having to be very thin in density, it will not require a lengthy one. In my experience, half of an ordinary wax match, burnt about six or eight inches above the printing frame, is ample, unless the cloud negative be very dense, which, of course, it ought not to be. An ordinary developer may be used to develop, but the development should only be carried, let us say, a quarter as far is necessary for the landscape slide. When the cloud cover glass is developed and fixed, place it against the landscape slide, film to film, but without permitting the two to touch, as one is, of course, wet; and observe if any portion of the cloud overlaps the landscape, shows through a mountain, house, or tree, for instance. Should it do so, then recourse must be had to a saturated solution of ferricyanide of potassium and hypo, which will, if carefully applied with a brush, and not used too strong, effectively remove all trace of the obtrusive cloud. This portion of the work is, however, very ticklish to do and only constant practice and a great deal of patience will successfully accomplish it. It is simplicity itself with what is known as a "Cirrus" cloud, but when one has to deal with clouds of the "Cumulus" description, it is far from easy. Some workers, however, contend that clouds should be made by reduction in the camera, for, by the contact method, the contention is that they "come out" too big in proportion to the landscape. There may be some truth in this, but I have never attempted it, and I should imagine it would be very troublesome, still more so than the contact method. It is, of course, quite unnecessary to add that the tone of the cloud, when developed, should match that of the landscape. In conclusion, may I express the hope that should any of your readers try my method, they will be successful?

HARRY HOLT.

PHOTOGRAPHING THE SEA BOTTOM.

It is natural enough that the recent tragedy in the North Sea should have aroused a strong desire for some investigation which would determine whether or not a disabled torpedo-boat may be lying on the Dogger Bank. To satisfy this desire certain suggestions have been made, as, for instance, that the shallows should be examined by dragging or explored by divers—suggestions by no means impracticable, but such as would assuredly entail not only much expense but a considerable loss of time, which at the present moment would not be willingly tolerated. There is another method, however, of making a survey of the sea bottom which is comparatively little known, writes the Rev. J. M. Bacon in the "Morning Post," and which does not seem to have suggested itself, though it could be adopted at a mere nominal expense and without any delay whatever. This method is that of photographing the actual shallows from a sufficient height overhead, and its practicability was fully tested by me two years ago in an experiment carried out, with the co-operation of the Admiralty, over the Irish Sea. It was precisely at this time of year, only in stormy weather and murky air, that objects on the sea bottom were clearly photographed, though lying at ten fathoms below the water's surface, and that surface strongly ruffled by a wind which had blown hard for a whole week. The photographic survey thus secured was, it should be mentioned, submitted for inspection both to the Admiralty

and to the Royal Society, and none but favourable criticism was passed on the results obtained. The photography in this particular case was carried out by a balloon, manœuvred across the sea; while a torpedo-gunboat was in attendance to render any assistance that might be required. In the case of the Dogger Bank, however, a reader and a far less expensive means could be adopted, which can be best understood when the rationale of the experiment has been explained.

THE NATURE OF CLOUDS.

It may not be generally known that in ordinary navigation, when some danger, as, for instance, a shoal, sunken wreck, or the like, is suspected of lying in a vessel's course but cannot be seen from deck, it is customary to send a man aloft, and the higher in reason that he can climb the further will his vision penetrate and the better will his eye command the view of any submerged object. And the cause of this may in part be at once made plain, for every one has noticed that in obedience to the laws of refraction, even in the clearest pool, it is only objects lying nearly vertically below which are seen with any distinctness, so that if, say, a sunken vessel were lying in a few fathoms of water and a man were looking down on it from a boat and floating somewhere just over its middle part, then that middle part might be fairly well seen, but the more distant parts fore and aft, being viewed at a slant angle, would probably be altogether invisible. If the observer were to be let up a quarter of a mile into the sky, however, and to look down thence, all parts of the vessel would now lie practically perpendicularly below and all would be equally well seen. The case is, of course, different when the surface of the water, being troubled, breaks up the rays which would otherwise pass through it. But the fact yet remains that when the eye is removed to a distance the distraction caused by the broken light largely disappears, and objects below can be seen more clearly. A very striking example, and so far proof of this fact, may be mentioned. Cloud is simply composed of particles of water mingled with particles of air, and though both separately are perfectly transparent, confused together they form a mass which stops and reflects back the light, and for this reason the illumined surfaces of clouds are white, yet in actual fact the stoppage of light is not so complete as it appears, and a thin veil of mist will behave precisely as the broken water's edge, obliterating the view at short range, but to a more distant observer allowing objects to be seen through it with tolerable distinctness. Thus it often happens that a balloonist, whose view of the outside world is wholly obscured by a shroud of thin mist, can be quite clearly seen by those at a distance. It should then be only in accordance with known fact if the secrets of the sea depths which hide themselves even from the trained eye of the sailor on board ship should become revealed to an aeronaut who will poise himself in space overhead, say ten times higher than the main-top.

OIL ON TROUBLED WATER.

But means may be readily adopted for very greatly reducing the disturbance on the surface of troubled water and of allowing vision to penetrate that surface. This is the time-honoured method of oiling the waves. So long and well has the truth of this method been established that we find it mentioned by Pliny as a fact turned to practical account in his day. Thus again so accurate and scientific an observer as Dr. Franklin calls attention to the same fact, which he verified by his own careful experiments one hundred and fifty years ago. On the same matter C. F. Gordon Cumming bears interesting witness, "Brought up," he writes, "in the heart of the Highlands, where the excitement of leistering salmon by torchlight on a dark night was a sport not altogether unknown even in days of Salmon Commissioners' and watchers and water bailiffs, we were well aware of the use often made of a good flask of oil in smoothing the surface of the deep brown pools in which the silvery fish lie all unconscious of the impending spear. And kinsmen returning from Bermuda have told us how the fishers there pour oil on the sea whenever the ripple prevents their seeing clearly enough to strike their fish, and also how those at Gibraltar do likewise to enable them the better to discern where the largest oysters are to be found." Should it then be desired to examine the shallows in so well defined and accessible a spot as the Dogger Bank it would be a simple matter to despatch any convenient boat with facilities for spreading oil—the required quantity of which is fabulously little—over the water bit by bit as it is examined. The method for conducting the photography remains to be provided. And here undoubtedly the readiest method is by utilising a kite. The height to which the camera should be elevated is, in my experience,

about six hundred feet. A box kite of very manageable proportions is well adapted for this purpose in an open sea, where sufficient breeze is not always in evidence, and in the exceptional event of actual calm the kite can be raised by the mere motion of the vessel. For the rest it is able to state from my own trials that practical details are of the simplest. The kite string is supplied by a twin wire, which is in connection with an electro magnet attached to the camera, and operating the shutter, the other end of the wire being connected up with a battery and push below under the control of the operator. A series of photographs, covering a very wide area, could in this manner be taken and developed within the daylight hours of a single day.

AMATEUR PHOTOGRAPHY FOR LADIES.

There are a great many women who would like to take up the art of photography, and who would, doubtless, find great interest and pleasure in it if they were not deterred by curious old-fashioned notions regarding the difficulties and expenses in connection with it. I was a writer in a recent issue of "The Queen." Time was when these drawbacks were very real; but every year has simplified the processes, and made the pleasures in connection with it greater and the pains less. One of the chief obstacles in the way of many is the absence of a room which may be used as a dark room. Of course, a properly appointed room is a great convenience, and to be obtained where possible; but at the same time, with management, good work may be quite well done without, and that independently of any special contrivances. It merely requires forethought and method, and all photographers ought to be both neat and methodical. It is doubtless a saving of trouble for lazy people to be able to leave all their dishes and bottles lying about in an apartment which no one may enter on pain of annihilation, but to keep everything away neatly and expeditiously in a cabinet becomes a task when it must be done. By the way, a chest of drawers is to be despised as a photographer's receptacle for his tools when it is a consideration, and when one must needs cover up one's camera. A small drawer for the developing apparatus, another for the printing materials, a third for storing negatives, frames, and so on. It is, of course, rather a trial to have always to go like a burglar—for darkness to arrive before commencing operations, but in time one comes to arrange things so that this is not upon merely as a matter of course, and, in fact, there are few places where there is no small room which can have some kind of temporary shutter arranged for occasional use, although it may not be practical to give it up entirely to photographic uses. When one becomes accustomed to working without a dark room it may be rather a bore to have to retire to its recess and conduct one's work in solitude.

Patent News.

Following applications for patents were made between October 1 and October 29, 1904:—

Printing Apparatuses.—No. 22,960. "Improvements in photo-printing apparatuses." Ferdinand Nusch.

Colour Photography.—No. 22,988. "Process of colour photography." A. Lumière et ses Fils.

Negative.—No. 23,064. "Improved photographic negative." Ada Hume Lucas.

Photographs.—No. 23,098. "An improved process of and means for the production of relief photographs or the like." Friedrich Gartner.

Copying Apparatus.—No. 23,228. "Improvements in photo-copying apparatus." Richard William Cunliffe.

Photography.—No. 23,291. "Means for rendering objects insusceptible to photography." Joseph Polak.

Exhibition.

PLYMOUTH EXHIBITION.

THE photographic section of the Plymouth Exhibition was opened on Wednesday, November 2, by Mr. W. Hurrell, Mayor of Plymouth, and a distinguished company of visitors numbering several hundreds. Though the actual exhibits numerically are not much greater than last year, yet the section is certainly stronger in artistic quality and technical excellence than on that occasion. It is as good an exhibition as has yet been held in the West, and should do much to popularise photography with a purpose. It has also demonstrated that there are workers in the West who are capable, but who hitherto, with undue humility perhaps, have not been seen at exhibitions. The section is a good one throughout, but probably suffers from over-classification. In these days there is not so much need for this as in the days when photographers produced photographs rather than pictures. And in saying this we hold no brief for those who make claim for photography as a fine art—with or without a capital letter. The distinction between the professional and the amateur was not sought to be made by comparison. There were two classes for professionals and two for amateurs, but these were for work dissimilar, where a definition was made; all the rest was without distinction. It is not a little curious that the professionals of the West proved averse to showing their ability in the work that is peculiarly their own—portraiture; and though there are a number of good portrait and figure studies, they do not fall into the class for portraiture. There is no class for landscape except for Devon and Cornwall scenery, and these prints, curiously enough, do not, in the matter of subject, follow very closely the definition. They would equally be suitable, in the matter of title, for a class not so defined. They are, however, an excellent lot. There was a good attempt to encourage architecture, two classes (one local) being given to it, but there were not so many exhibits as might have been expected. Classes devoted to miscellaneous work were the best filled, and in them were found examples of work that might have come within a closer definition, as in the other classes. All of which goes to show that an exhibition without classification might have been attempted. But the purpose in organising the exhibition, the encouragement of photography in the West, was eminently successful and deserves praise.

Class A.—Portraiture (professional, open) was small, and it is curious to note that contributions to it came from the almost furthest west point in England, and from very far north in Scotland. The first prize was withheld, and the second went to Mr. F. A. Swaine, Southsea, for his "A Difficult Piece for Grandpa," a little girl holding up a piece of music for grandpa to play as a violin solo, in which pose and expression are natural. The technical quality of the work is good also. "Lead, Kindly Light," by the same exhibitor, secures the third place, with a study of a nun's head and shoulders. A diploma of merit is awarded to V. T. Paul, Penzance, for "Master Alec Forbes," a portrait study, certainly unconventional in pose and arrangement.

Class B.—Miscellaneous (professional, open)—Though not a big class, it is of more than average merit, and has some very nice things in it. Technically, the whole class is strong. F. W. Beken, Cowes, has a fine series of yachting studies, with one of which, "Marine Study," he secures a third prize. E. Seymour, Watford, is strong in his examples of flowers and fruit, the skill of which, both in arrangement and technically, is clearly evident. He is awarded first for "Flower Study," an exquisite arrangement of chrysanthemums; and second for "Currants," the texture and quality of which are very fine. He is awarded a diploma for "Nettles," a clever study. D. W. Kyle, Anderston Cross, Glasgow, has two fine examples of flower photography in "Pæonies" and "Lilies," the former, perhaps, the finer. A. Debenham, Ryde, has much variety in his exhibits, but his "Sweet Seventeen" is his best, and to this the judges gave a third prize. "Prince," a study of a perky little dog, by Chas. Treasurer, Inverness, is a very attractive work. Graystone Bird, of Bath, in "On the Way to the Spring," is not, we think, quite up to his best. A. G. Gibson, Penzance, has two striking studies of the sea—both wrecks—"The Trail of the Storm," a ship high and dry

on a beach, for which he is awarded a diploma, and "Foundering," a brave steamer with the sea washing over her upper deck.

Class C.—Architecture (amateur, open).—An excellent class throughout, well-chosen subjects in most cases, and well treated. Rev. S. J. Clark, Newnham-on-Severn, has work of great interest, securing a diploma for "The Triforium," an honour very fully deserved. S. G. Kimber, Southampton, is, of course, well represented (he could hardly be otherwise with his experience), and is awarded third for "A Shaft of Light," a very clever and capable piece of work. J. W. Smith, Falmouth, contributes a number of architectural things in one frame, several of them of merit, but this way of exhibiting is not the best possible treatment of such subjects. "St. Mary's, York," by A. Macpherson, West Norwood, is a clever study. R. Morris, Ivybridge, contributes a most excellent interior in "Pisa Cathedral," a subject demanding great care in treatment and happily secured. A. W. Walburn's "An Old-time Street" is a very charming production. W. A. Clark, Moseley, in "Crypt, Winchester," and "An Abode of Ancient Peace," is to be congratulated upon work of the best quality and great breadth of treatment, for the first of which a first prize is awarded. "Unto Eternity," W. G. Hill, Eaglescliffe, is an architectural study in which a tomb is included, with a very felicitous treatment, harmonious with the title, which has secured a second prize.

Class D.—Miscellaneous (amateur, open).—This is a good class throughout, strong in number, and technically and pictorially calling for praise. Of course, it ranges over the wide field of photography, from the purely scientific to the picturesque, and in each case well represented. W. H. Waterfield, Stonehouse, is represented by "Idle Moments," a study of a boy and ducks, very happy and pleasing. W. M. Martin, Redruth, makes a specialty of scientific work, and is represented here, as at the Royal, by "Embryology of a Chicken," showing the development of the chicken from the egg, for which an extra prize has been awarded. His "Radiograph of a Pigeon" is a wonderfully clever thing, showing also the value of radiography for diagnosis. C. F. Grindrod, Malvern, is splendidly represented with some head studies, fine rugged faces, well and naturally posed, and admirably lit. His "Ploughing on the Upland" and "Cutting Oats" are pictorial in a high degree, but the former suffers slightly from the somewhat exaggerated size of the man. For his "Cornish Fisherman" he is awarded a second prize. A. B. Fellowes Pryme is up to his usual standard of excellence, and of his exhibits perhaps the best is "A Rest by the Way." J. W. Catford, Devonport, is awarded first prize for "Morn," an excellent study of early day, but with a somewhat heavy foreground, and rather too pronounced. It is, however, stronger in all qualities than his "Rushes." A. Edmund Spender, Plymouth, contributes several prints, the most pictorial of which is "The Cradle of British Commerce," a study of a sailing ship. A. H. Harding, Plymouth, has some capital woodland studies, of which perhaps "Woodland Beauty" is the best. E. Salisbury Tardrew's (Croydon) "Idle Moments" is a very natural example of posing, a young woman with some time on her hands sitting on the end of a table. R. Morris's "Une Bonne Histoire" is a most enjoyable rendering, a group on the deck of a steamer listening to the good story that one is telling, and at which all are laughing. C. H. Rogers, Swansea, is awarded a diploma for his "Fruit," a well-arranged example of grouping. Percy B. Williams has a very nice picture in "A Hertfordshire Stream." Of the Rev. A. G. Chapman's (Tintagel) contributions "Sheep on the Headland" is the best, and a very enjoyable picture, quite suggesting outdoor and sunlight effect. Charming and enjoyable in every way are the prints of G. B. Clifton, Ealing, the best of which undoubtedly, "A Lone Wood's Unfrequented Path," is awarded a diploma. John Smith's (Hastings) "Study of Old Age" very deservedly secures a third prize, though his "Veteran" and "An Old Salt" approach it closely. There is much merit in "Sunrise from Schlossberg," Miss Boucher, Plymouth, but the difficulties of the subject are rather against a more artistic treatment. Henry W. Bailey, Totnes, in "A Misty Morning," does convey the idea of such a condition, and, what is more, has chosen a pictorial subject, handling it very capably. Will H. Foxall, Tunstall, quite deserves his diploma for "Toilers of the Harvest," a small print, but full of much artistic feeling. John R. Sandilands (Edinburgh) "Cranford Brig" and "At the Close of the Day," the latter of which has deservedly had a third prize, are most enjoyable. An extra prize

is awarded to "Virginian Creeper," C. L. Williams, Redruth, for a decorative treatment of foliage. "Here She Comes," by C. Newton Abbot, a study of a fishing-boat entering a harbour of merit, and the glint and shimmer of the sea of the foreground is very natural.

Class E.—Devon and Cornwall Scenery (open).—Without most of the scenes are to be found in the two counties named, they do not all carry out the idea prominently. W. O. S. King, Maidenhead, has "Four Views on the River Lyn," which is all interesting. "Shaugh Bridge," W. H. Waterfield, Stonehouse, Devon, is acceptable. G. W. Pitt's (Barnstaple) "Lynmouth" is characterised by good work. "St. Michael's Mount," V. T. Penzance, though pictorially excellent in the matter of point of view, is rather muddy and choked up. The same worker's "Fishing Boats" is a very pictorial treatment and a most enjoyable picture, which a second prize is given. He is awarded a diploma for "Kinsale," a study of a fishing boat. Rev. A. G. Chapman, Tintagel, has a rather interesting selection, in which the excellence is not so good as it might be. "Early Morning, Pool," E. F. Jarvis, Plymouth, a very happy rendering of the subject, is awarded a diploma. A third prize goes to Fredk. J. Plymouth, for "Mar's Hill, Lynmouth," a very well-deserved. Undoubtedly the finest print in the class is "A Glean of Light," W. Clayden, Plymouth. The subject is a soft shimmering, hazy atmosphere, fishing boats near and further away, the most picturesque in arrangement. This secures the first prize and the diploma of honour for the best picture in the exhibition.

Class F.—Postcards (sets of four).—These very popular things have now invaded photographic exhibitions, and this class is certainly meritorious and of as high a standard as any, though, of these are examples of "the usual thing" in it, as we suppose always will be in every exhibition. The range of subjects is wide—fruit, flowers, streets, old houses, shipping, landscape, and anything between. The prizes have been won as follows:—First, J. H. Saunders, Burmantofts, Leeds; second, E. S. Watford; third, W. H. Foxlee, Tunstall; diploma, Fred. Hastings (2).

Class G.—Architecture (members of Devon and Cornwall Photographic Societies).—Though not a very strong class, this is of a very high standard. Carslake Winter Wood, Paignton (Torbay Camera Society), has a number of good things, the best of which is, undoubtedly, "South Door, Kenton Church," for which he is awarded a first prize. R. Morris, Ivybridge (Torbay Camera Society), secures a second prize with "Jewish Synagogue, Nürnberg," a subject pictorially well arranged and making a very pleasing effect. E. G. M. Paignton (Torbay Camera Society), has four good subjects, of which he is awarded a first prize for "North Choir Aisle, Tewkesbury Abbey," a full of fine quality, run very close indeed by "The Cloisters, Worcester Cathedral." Frederick Johnson's "Haddon Hall" has merit.

Class H.—Miscellaneous (members of Devon and Cornwall Photographic Societies).—Carslake Winter Wood, Paignton (Torbay Camera Society), shows a very excellent little picture in "Mid-day Slapton," for which he is awarded a diploma. A. B. Fellowes (Plymouth Photographic Society) is well represented, both technically and pictorially, and is awarded a first prize for "On the Vire," a happy snap of two terriers on a sandy beach, in the foreground of which are faint reflections of the dogs, behind being a steep sea and cliffs far away, the whole soft and tender. Of the popularity of the picture there can be no doubt. He secures a third prize for "Portrait Study," and a diploma for "Her Favourite Pose," a charming study of a little girl. Diplomas are awarded to C. H. D. (Plymouth Photographic Society) for "An Anxious Moment," a finely arranged group of boys engaged in a game of marbles, and "Farrier," an excellent picture in which horse and man play a part. "By the Roar of the Sea" is a fine study of a dog lying on a rocky shore. His "Portrait of a Lady" is evidence in portraiture which he has not often called into play. "Lilac" is a meritorious flower study by Mrs. Marillier (Torbay Camera Society), and equal to it is her "Toilers of the Sea," a group of fishermen at a quay. A. E. Coleman, Plymouth (Plymouth Photographic Society), has three meritorious works; the cleverest is certainly "Strike

"Iron is Hot," an artistic rendering of the operation of welding on an anvil in a blacksmith's shop, full of difficulties well overcome. Morris, Ivybridge (Torbay Camera Society), in "Lake of Annecy," is a quiet, reposeful landscape of much pictorial quality. Miss E. L. Millier (Torbay Camera Society) has a clever print in "Study of Argyranthemum," full of fine gradation and good half-tone. F. W. Packard, Bideford (Bideford Camera Club), has a charming subject in "Low Tide," the fine stretch of flat sand being admirably handled. Harrowing," E. V. Hearn, Plymouth (Plymouth Photographic Society), while depicting an agricultural operation that is not usually associated with the picturesque, manages to impart a great deal of quality to his rendering by the factors he gathers into his subject. "Evening in Harbour" is a very enjoyable subject and is awarded third prize. Of the several pictures E. J. Jarvis contributes, two and out from the rest by their pictorial qualities—"Pride of the Morning" and "Through the Morning Mist," both of them studies of fishing craft seen through the hazy light of a grey morning. The one of these is awarded a second prize. "Cattle at Valle Crucis," Fred. K. Johnson, Plymouth (Plymouth Photographic Society), has considerable attraction, although the cattle do give a somewhat spotty character to the print. "The Widower," R. Burley, Truro (Cornwall Central Photographic Club), is certainly a fine composition and of excellent technique. For a very excellent work, "A Study of Home Life," Mr. W. Clayden, Plymouth (Plymouth Photographic Society), is awarded a third prize. Class I.—Miscellaneous (boys and girls under 18).—These are days when the young idea shoots with a snap-shot camera, and so it was thought wise to encourage youth in this way. The result in point of numbers is small, but the work is certainly highly meritorious. "Study," by Eddie Jarvis, Plymouth, is a creditable bit of portrait work. W. Gundy, jun., Balby, Doncaster, for "An Impending Storm," a landscape with a strong sky, is given a second prize. "Evening Calm," C. A. W. Duffield, Maidstone, secures a third prize. Diplomas are given to Harry Hill, Stoke, Devonport, for "Plymouth Church," and to C. A. W. Duffield for "Old Hastings." There are some very fine pictures exhibited by Wellington and Ed. Elstree, showing the possibilities with their bromide and other plates. Henry F. Purser, 35, Charles Street, Hatton Garden, London, W., representing the Busch Camera Co., has a splendid lot of prints showing the power of the Busch lenses. The exhibition has already been crowded, and as it runs to the end of the month, it is expected to be very popular, as excursion trains are being sent from all points in the West. The judges of the photographic exhibition were Mr. Walter D. Finch, head master, School of Art, Teignmouth, and Mr. H. S. Hill, Plymouth, a past-president of the Plymouth Photographic Society. Their awards have given the greatest satisfaction. The management of the section is in the hands of Mr. M. R. Rowe, M.J.I., and Mr. E. Croft, to whose admirable hangings much of the success of the show is due.

FORTHCOMING EXHIBITIONS.

- November 2-23.—Plymouth. Hon. Sec. Photographic Section, M. R. Rowe, 2, Walnut Villas, Cockington, Torquay.
 November 15-19.—Sunderland Camera Club. Hon. Sec., Selby-Ord, Frederick Street, Sunderland.
 November 17-18.—Braintree and Bocking Camera Club. Hon. Sec., W. H. Tilsdon, 81, High Street, Braintree, Essex.
 November 17-19.—Darwen Photographic Association. Hon. Sec., G. Thomas.
 November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
 November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Brown, 37, Henley Road, Ipswich.
 November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Meant, 55, The Drive, Hove.
 November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., W. Simmers, Aberdeen House, Ramsgate.
 November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarock Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.

December 2-3.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 12-14, 1905. Boston Camera Club. Hon. Sec., H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905. — Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Sec. John B. Parnham.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

A GENERAL meeting of the Arbroath Amateur Photographic Association was called for last week, but owing to the lack of interest displayed by the members it was resolved to dissolve the Association.

SOCIETY OF ARTS.—The Society of Arts will commence its fourth half-century on the 16th, when Sir William Abney, as chairman of the society's Council, will open the 151st session with an address. The subjects on which papers will be read at the meetings before Christmas include "British Trade," "Canals," "The St. Louis Exhibition," "Patent Law," "Burma," and "Street Architecture." There will also be a course of lectures on wind instruments, with musical illustrations.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
12.....	Croydon Nat. Hia. and Sc. Soc.	Messrs. R. & J. Beck's <i>Noctelles, Lenses, Hand Cameras, Day-light Changing, Tele-photography, &c.</i> Demonstrated. Mr. W. F. Slater, F.R.P.S.
14.....	Optical Society	<i>Periscope Lenses.</i> Mr. W. A. Dixey.
14.....	Luton Camera Club	<i>Carbon Printing.</i> Demonstrated. Mr. John W. Gear, F.R.P.S.
14.....	Southampton Camera Club	<i>The Cathedral of Winchester.</i> Illustrated. Mr. S. G. Kimber.
14.....	South London Photo. Society.....	<i>Developers and Developing.</i> Mr. Charles F. Dickinson.
15.....	Blairstown and Dis. Ph. Assn.	<i>Ruskin as an Art Critic.</i> Mr. H. D. Ross.
15.....	Birmingham Photo. Society	<i>What is Art?</i> Mr. R. Catterson-Sold.
15.....	Devonport Camera Club	<i>Stereoscopic Photography.</i> Mr. J. Batten.
15.....	Brentford Photo. Society	Lantern Evening.
15.....	Croydon Nat. Hia. and Sc. Soc.	<i>Bernhardy Priory.</i> Illustrated. Mr. N. P. Roberts, F.G.S.
15.....	Nelson Photographic Society	Members' Print Evening.
15.....	Hackney Photo. Society	Excursion Prints Judged and Criticised.
15.....	Glasgow Southern Ph. Assn.	<i>Résumé of the Summer Outings.</i> Mr. W. H. Wilson.
16.....	Everton Camera Club	<i>Three-Colour Photography.</i> Demonstrated. Mr. J. Mansell.
16.....	Windsor Camera Club	<i>Rising to the Occasion.</i> Mr. Walter D. Welford, F.R.P.S.
16.....	North Middlesex Photo. Soc.	Lantern Slides. Mr. A. H. Lisett.
16.....	Crickwood Photo. Society	<i>Photographic Christmas Cards.</i> Demonstrated. Mr. F. Carter.
16.....	Redhill and Dis. Camera Club.....	<i>Auto-Dichromate Printing.</i> Demonstrated.
16.....	G.E.R. Mechanics' Institution	Judging of Prints and Slides.
16.....	Boro' Poly. Photo. Society	Lantern Night.
17.....	Hull Photographic Society	<i>Photography Prize Slides.</i>
17.....	London and Prov. Photo. Assn.	<i>Binocular Vision and the Theory of the Stereoscope.</i> Mr. T. W. Baiber, M.I.C.E.
17.....	Richmond Camera Club	<i>Lantern Slide Making for Beginners.</i> Mr. Cheese.
17.....	Southport Photo. Society.....	<i>Chloro-Bromide.</i> Demonstrated. Mr. W. Parkinson.
17.....	Liverpool Amateur Ph. Assn.	<i>Various Methods of Improving Faulty Negatives.</i> Demonstrated. Mr. F. Anyon.
17.....	Leigh Photographic Society	Thornton-Pickard Ltd. Prize Slides.
17.....	Watford Camera Club	Thornton-Pickard Co.
17.....	Watford Camera Club	Royal Photographic Society's 1904 Prize Lantern Slides.
17.....	Ta'ing Photographic Society	<i>Rising to the Occasion.</i> Mr. Walter D. Welford, F.R.P.S.
18.....	Redhill and Dis. Camera Club.....	Annual Exhibition and Conversation.
18.....	Boro' Poly. Photo. Society	<i>Bromide Printing.</i> Mr. F. W. Gregg.

ROYAL PHOTOGRAPHIC SOCIETY.

TUESDAY, November 1, 1904. Mr. George Lamley in the chair. Mr. W. Thomas gave the first of the new series of lectures, from a practical standpoint, on the various branches of photography, which were organised by the Council last season and attained such success. The first series was upon the different printing processes at present in vogue, and the present we understand is to deal with the obtaining of the negative.

The present subject was the negative in landscape photography, including composition, the use of lenses of varying foci and so forth. In his opening remarks Mr. Thomas said that he did not purpose developing a plate although the syllabus termed it a demonstration, nor did he propose, except in so far as it might be necessary in dealing with the slides which would be shown, to touch upon apparatus.

Why was it, the lecturer asked, if two equally clever photographers were out together, while the works of one appeared in exhibitions those of the other never attained publicity. It was because one had learned to "see" and the other had not. When you go out to photograph you must have a very distinct idea of what you are going to do. If you look at the material either as self-contained or merely as the framework, you will find that what you might be inclined to describe as a miserable flat place, provided you with an endless fund of material. In monochrome works shade represents colour, and the lecturer showed a chart of washes of colours which one meets with in Nature, and alongside of these, the colours, or shading colour, which an artist uses when he works in monochrome; different shades should express different colours. A number of slides were then shown to demonstrate the use of lenses of various focal lengths. Very often it happens that a subject is so constituted that you cannot give it the

amount of exposure it demands, and the resulting negative is. If, however, you introduce a certain amount of diffusion it is found that the gradations are evened up, and a pleasing result obtained, impossible by other means. The advantages of long lenses appear when we get into open country, when, owing to configuration, we cannot choose our standpoint so as to use a small angle lens, and for this purpose the lecturer uses spectacle lenses. The great advantage of the modern high-class lens is that you can with it on dull and even foggy days, and Mr. Thomas showed a photograph taken on such a day with a lens working at $f/2$. The lecturer then dealt with plates, showing a number of negatives, through the Chapman-Jones plate tester. He took a certain number of plates made in four varieties. The first, an ordinary, orthochromatic one, the second sensitive to green and yellow, the third sensitive to red and yellow, and the fourth to red, yellow and green. These were all exposed for approximately the same time on the plate tester, and the results were most marked, for where an ordinary plate rendered only the green and blue, the panchromatic rendered all the colours on the plate tester and practically correct compared with the chart we have already mentioned. Slides were also shown of a hedge containing masses of brilliant yellow flowers. That from a negative on an ordinary plate did not at all differ between the green hedge and the flowers. Next an isochromatic was used, but the ultimate and true result was obtained by use of an isochromatic plate used in conjunction with a colour filter.

Mr. Thomas' method of development is to have two dishes, one containing rodinal 1:15—instead of about 1:30 as usually recommended—the other containing the following developer.

No. 1.

Hydroquinone	1 oz.
Sodium sulphite	2 ozs.
Pot. bromide	1 oz.
Boiling distilled water	12 ozs.

No. 2.

Sodium carbonate	2 ozs.
Sodium sulphite	2 ozs.
Distilled water, to	12 ozs.

For use take equal parts of each. The plate having been exposed, is put into the rodinal solution and immediately the image appearing is transferred to the hydroquinone.

The lecturer strongly advised making rough sketches for reference, and if one could not do this the next best thing was to photograph simply as studies. From these it was possible to get what manner of treatment, whether under a different condition of lighting or otherwise, would best do justice to the subject. A great advantage is that in revisiting some scene no time is wasted in selecting one's point of view—or perhaps even in finding the subject—and in this way the lecturer has exposed a couple of dozen plates in two hours, whereas without his sketches he would probably have been unable to get but a very small portion of the pictures he required. Even with simple material something can be done under such conditions of lighting and so forth.

An actinometer is, said Mr. Thomas, a very useful article, but many sneer at it as they do at a number of other useful things. When you do marine work you must remember that the same conditions apply as with landscape. There is the dark colour of the rocks and the high actinism of the sky and sea to render all of them together an isochromatic plate and screen are necessary.

With regard to halation, this can be practically overcome by use of full exposure, and Mr. Thomas showed two slides of a hospital which were certainly very convincing, there being practically no trace of halation, although in one case the sun was streaming through the windows.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 3RD.—Mr. R. P. Drage in the chair. The chairman, in a few well-chosen words, on behalf of the association, presented A. Teape, the gold medal of the Henderson Award, which he had won for his paper, entitled "Intensification Without Metallic Salts." Mr. Teape, after thanking the members for the award, said that an exception had been taken to the title, because a metallic salt was used, but he would explain that that was only a matter of convenience.

chlorine or bromide water would rehalogenise the negative image, would not be so convenient to use. A series of portrait studies by Mrs. Welford were projected, and from the frequent applause were clearly thought of high artistic and technical excellence. Mrs. Welford described her arrangements for portraiture in a conservatory at the south, and showed how good work can be done under difficult circumstances.

Mr. Freshwater revived the memory of his summer holiday by exhibiting a series of views in Cornwall. Mr. Ellam's contribution to the exhibition consisted of a series of remarkable photographs of birds and their nests.

CAMERA CLUB.

At the weekly meeting Mr. G. E. H. Rawlins brought before the club a printing process, which he has named "Oil Printing," and gave a demonstration of the same, which excited great interest. He does not claim originality of the process itself, but takes credit for its application to a particular kind of photograph. As a matter of fact the method was patented as early as the year 1855, by Poitevin, who heads his specification "Improved Photographic Printing" (December 13, No. 2,815), and the invention has been half a century before the world without being taken up by photographers with any exuberant eagerness. We are led to assume that it does not appeal to them as being variable to better known methods of producing prints.

There is so little difference between Poitevin's method of procedure and that of his modern disciple, that if we quote from the specification, number and date of which has just been given, we shall at once get a grip of the process. "A concentrated solution of albumen, gum arabic, gelatine, or similar organic substance," is mixed with a solution of a chromate or bichromate of potash, and is spread upon the surface which is to receive the design." Such surface may be a lithographic stone, metal, glass, wood, or any other material. The picture is impressed upon the sensitised surface by the agency of light, after which "a greasy ink" is applied to it, when the ink will be found to adhere to those parts only which have been affected by the light, and the print thus obtained "may be retained on the surface on which it is first produced," or impressions may be taken from it in the manner of lithographic printing. A design in various colours may be produced by suitably applying different colours to different parts of the surface.

Mr. Rawlins does not go so far as Poitevin, he uses gelatine only, and the material upon which the gelatine is spread is paper. He makes no reference at all to the lithographic possibilities of the process, and says nothing about printing in more than one colour at a time.

It may fairly be asked, Why has this somewhat ancient method of printing been suddenly recalled from the files of the Patent Office? Rawlins explains the problem in this way. He had long been dissatisfied with existing methods of photographic printing were unsatisfactory, in not giving the operator that amount of "control" over his work which is desirable. The gum process he thought well of, but in objection to it was that in the effort to control the effects there was a risk of pulling the image entirely to pieces. It was an analytical process, and he was looking for a synthetical one, in which the image, as parts of the image, could be built up, as well as taken down. And he experimented with this oil process, and found that it gave him what he wanted.

His method of going to work—and we must give him full credit for working out all the necessary details—is as follows:—Good quality paper, or other paper, is coated with a solution of plain gelatine, which some hardening agent, such as chrome alum, or formaline, has been added. The paper is dried. When wanted, it is sensitised by dipping upon a 24 per cent. solution of potassic bichromate, with the usual precautions common to the carbon process. The paper is exposed to a negative and transferred to a water bath, when the lights are washed up and remain absorbent, while the shadows of the picture retain their little water. When drained and surface dry, the print is laid, face upwards, on a sheet of plate glass, and is rolled with printer's ink which has been reduced to a creamlike consistency by the aid of turpentine. The roller which he advocates is an ordinary india-rubber roller squeegee. The ink clings to the shadows but is rejected from the lights, so that the result is a positive in oil pigment. Slow even pressure will ensure a good coating of ink, while quick and light

motion of the roller will remove the ink from the surface, so that the operator can deepen his shadows or lower his lights, according to his own sweet will.

It will thus be seen that the resuscitated process is one for the "pictorial" worker to play with. And certainly in one respect it is better than the gum process for such adventurous use, for the bichromate image is so persistent that it cannot be eliminated. The operator will therefore be found to reproduce the general lines of his picture, but he can modify the lights and shades to any extent which he may desire. We do not think that the process will be of much use to the professional photographer. Indeed, had that been its destiny it would not have remained, as we have already hinted, in abeyance for fifty years.

CROYDON CAMERA CLUB.

Mr. A. W. GREEN, representing the well-known firm of Messrs. John Griffin and Co., gave a clearly worded and interesting exposition on "Enlarging at Home Without Expensive Apparatus." The fact that the apparatus in question consisted mainly, if not entirely, of enlargers placed on the market by Messrs. Griffin did not detract from the utility of the subject matter in the least, as those shown were varied in character, and also, within moderate limits, in price. Perhaps of all the enlargers shown the Series C. attracted most attention, and deservedly. These are of the familiar double camera type, and are fitted with a most ingenious link motion, which automatically moves the lens in relation to the sensitive paper, or plate, as the case may be, and also adjusts the negative in correct ratio, the sensitive surface and the negative thereby occupying conjugate foci. By this means visual focussing can be dispensed with, and the worker, by consulting a scale on the baseboard, can enlarge to various predetermined sizes or reduce, with every assurance that the results will be sharp. A cordial vote of thanks to Mr. Green was adopted.

WOODFORD PHOTOGRAPHIC SOCIETY.

THIS Society met as usual last week, at the Wilfrid Lawson Hotel, and the president for the current session, newly elected at the last meeting, took his seat for the first time. Mr. Wilmer acknowledged in a few straightforward and graceful sentences the honour the members had done him in electing him, and *en passant* paid a warm tribute to the useful work done by the late president, Mr. F. G. Emler, who this session returns to his no less useful secretarial duties, and in conclusion expressed the hope that when he came to lay down the reins of office he would find the Society in the same flourishing state as that in which he now found it. Mr. Hillsworth then showed as an object of interest a newly-brought-out stand development tank, the "Standa," supplied by Messrs. Houghton's, Ltd., and showed some negatives developed by its aid. The lecturer for the evening, Mr. McIntosh, of the North Middlesex Society, who was accorded a cordial reception, then gave his lecture on "Orthochromatics." Mr. McIntosh, in the course of a lucid and closely reasoned lecture, advocated the use of screens with colour sensitive plates, and in particular mentioned that he had done good work with a green screen of his own make, specimens of the work of which were handed round and met with much admiration. He then showed how to make such a screen by actually preparing one before his audience, and altogether made a most practical and interesting speech.

Some discussion ensued, in which Messrs. Malby, Marriage, Wastell, and Carpenter took part, and a very hearty vote of thanks to Mr. McIntosh closed the proceedings.

THE death took place last week, at Blackpool, of Mr. J. Wilde. Deceased, who was 72 years of age, was a native of Oldham, but took up his residence in Blackpool some forty years ago. For many years he carried on the business of a photographer in Talbot Road, but latterly had lived in retirement. He was a member of the Fylde Board of Guardians, and when the borough bench was created he was made a Justice of the Peace. Mr. Wilde was a Liberal in politics, and on two occasions sought municipal honours in Talbot Ward, but was unsuccessful. At the present time his son, Mr. Milton G. Wilde, is one of the representatives of this ward. Deceased leaves a widow, two sons, and a daughter.

News and Notes.

ENTRIES for the Hove Exhibition must reach the hon. secretary, 55, The Drive, Hove, on or before Monday, November 14.

THE Optical Society's next ordinary meeting will be held on Monday, the 14th inst., at 8 o'clock p.m.

THE Leicester and Leicestershire Photographic Society intends holding its next exhibition from March 27 to April 1, 1905.

ROYAL INSTITUTION.—A Christmas course of lectures, adapted to a juvenile auditory, will be delivered by Mr. Henry Cunynghame, C.B., on "Ancient and Modern Methods of Measuring Time" (experimentally illustrated). The dates of the lectures are December 27, 29, and 31, 1904; January 3, 5, and 7, 1905.

THE Hastings and St. Leonards Photographic Society's photographic exhibition will be held at the Public Hall, Hastings, on Wednesday, Thursday, and Friday, January 11, 12, and 13, 1905. The judges will be Mr. A. Horsley Hinton (editor "The Amateur Photographer") and Mr. John H. Gear, F.R.P.S. The Hon. Secretary is Mr. Fred Judge, 21A, Wellington Place, Hastings.

THE members of the Linked Ring held their annual smoking concert at the Dudley Gallery, Egyptian Hall, Piccadilly, on the evening of Tuesday, November 1. The function, which was in every way enjoyable and successful, should be memorable as the last of the series to take place in the Gallery, as next year the Photographic Salon finds it necessary to seek new premises for its exhibition.

INFORMATION has been received that the St. Louis Exhibition have awarded a silver medal to the Royal Scottish Agricultural Society for the exhibit of photographs of American conifers grown in this country. The pictures—twelve in number—were enlargements of photographs of trees, growing at Scone and Murthly, taken for the purpose by Mr. A. D. Richardson, the society's photographer.

THE last sale of section 4 of the final sale of the Marquis of Anglesey's effects realised £200. The best price (£34) was paid for a bedroom suite in walnut, and £15 was the price of an electric portable Turkish bath. Among the photographs were two presented by the students and professors of the University College of North Wales "to Boy Blue, in appreciation of his invitation to the Gaiety Theatre pantomime." A local tradesman secured the pair for three shillings.

MR. LAFOSSE (of Messrs. Illingworth and Co.) gave a demonstration of carbon printing by the single and double transfer process to the members of the Windsor Camera Club on Wednesday, November 2, which was much appreciated, and on the motion of Mr. C. C. Harrison, seconded by Mr. T. J. Cartland, a vote of thanks was accorded to the firm, and to Messrs. Russell and Sons, of Windsor, for kindly lending the utensils necessary for the demonstration. On the 16th Mr. W. D. Welford delivers his lecture entitled "Rising to the Occasion."

THE British Optical Association Examination.—An examination of candidates for admission into the British Optical Association was held in Glasgow on October 31 and November 1 at the Shepherd's Hall, Bath Street. This has been the most successful examination yet held in point of numbers. The examiners were Mr. J. T. Graddon, M.A. (Oxon.), for the Practical Section, and Dr. E. H. Cook, Assoc.R.C.Sc., for the Theoretical Section. The next examination in London takes place on December 6 and 7, and there will be another in Glasgow in February, 1905.

PHOTO Micrography.—A lecture on the technique and application of photo micrography was delivered last week before the members of the Birmingham Scientific Society by Mr. J. Dancer Whittles. The lecturer remarked there was no doubt that the great advance made in photography was due to the perfected dry-plate, which was the veritable handmaid of science. Although book illustrations of the highest order had been made by fine-line drawings, etc., they were now being replaced by the actual photo-microgram. The lecturer then traced the history of photo-micrography from 1865 down to the present time, and illustrated its utility to the research worker for making permanent records of certain phenomena which might only have been transient. He instanced the utility of the photo-micrograph in the study of pathology, and exhibited micrograms taken of the blood of persons suffering from the new disease known as "craw-craw."

RADIUM and Radiographs.—Mr. C. Thurston Holland, in his dental address last week to the members of the Röntgen Society, 20, Hanover Square, dealt almost entirely with the value of in relation to medicine and surgery. The discovery of radium, said, had created the belief that it would make it possible to dispense with all the paraphernalia connected with the X-rays, but result had not been secured, and it was not now expected to be a substitute in the treatment of malignant growths. Their abundant evidence to show that most successful effects had been secured by radiography—its use, indeed, was now almost indispensable for medical men. There was an impression that the process was dangerous one, but it could be used both safely and beneficially by a well-qualified man who was skilled in radiography. He had said himself with most favourable results, and he was sure that it would prove still more useful in the future than in the past.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, the 7th inst., at 4.30 p.m. Sir James Crichton-Browne, treasurer and vice-president, in the chair. H.H. the Raj Rana Bhawani Singh Bahadur of Jhalawar, 1st, and Mr. E. J. Preston were elected members. It was announced that the Institution had received a bequest of £100 from the will of the late Miss Harriet Jane Moore. The special thanks of the members were returned to Dr. Ludwig Mond for his donation of £755 for the purpose of erecting a lift from the basement to the second floor of the Institution, and any surplus after the completion of the work to go to the Research Fund. During the reconstruction of the entrances and exits of the lecture-room of the Royal Institution, the room had been materially improved by the erection of two covered-in iron cases and the widening of the doorways, and the ceiling has been considerably raised.

THE late Basil Bradley.—The death of Mr. Basil Bradley, R.C.S.D., of Locket Road, Wealdstone, who poisoned himself with carbolic acid on Sunday week, was investigated by a coroner's jury at Wealdstone on Monday. A verdict of suicide while temporarily insane being returned. The son of William Bradley, a portrait painter, he was born in 1849, at the age of fifteen started life as a photographer's assistant. He subsequently became an assistant portrait painter, and at the age of nineteen he definitely decided to embark on an artistic career. Five years later he was elected an Associate of the Royal Society of Painters in Water Colours, and in due course he became a full member of the body. His works in water-colour include "The Challenge," "Lingham Castle," "Full Cry," and "A Lift on the Way." Bradley also painted in the stronger medium of oils, and exhibited a number of oil paintings at the Royal Academy, among them "Victor and Vanquished" and "July on the Thames," 1878; "Time," 1882; "Gathering the Sheep," "Midsummer on the Thames," "Hard Times," "Twelfth of August," "Caledonia," and "A J. Idyll."

ROME in Bayswater.—Mr. Robert Arthur invited representatives of the Press last week to the Coronet Theatre to witness a photographic exhibition of illuminated and coloured pictures of Rome thrown on a white screen on the stage by a very large and excellent lantern. It may be said at once (says the "Daily Telegraph") that no better of their kind than the photographs here presented by Signor Eugenio Inguimbart has ever been seen. They cover an enormous extent of interesting material, dealing with the architecture and unrivalled art treasures of St. Peter's and the Vatican. In the way of detail reproduced, only one single example of bad focussing is observable, the right hand of the Belvidere Apollo. The rest is simply astonishing in the life-like appearance of atmosphere, reality and space obtained by the careful colouring of the slides, the judicious management of the lantern. In many cases the effect looked as if it was filled with real statues, and had suddenly been transformed into a Papal gallery. The educational value of the exhibition is undoubted. Every school in London and near it should be taken to see this collection of pictures, statuary, and buildings. A suitable time should be fixed upon for studying each scene before the next is produced; and a short, crisp, running commentary with an audible voice is the only necessary addition to explain the value of the masterpieces of art or relics of history presented one after another. The management of the Coronet Theatre may be congratulated for their enterprise in producing so fine an intellectual entertainment for the pleasure and benefit of Londoners.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

LOST CAMERA AND LENSES.—A WARNING.

To the Editors.

Gentlemen,—The camera and lenses mentioned below were stolen Friday, the 4th inst., from a messenger from the City Sale and Exchange, Aldersgate Street, E.C. Will you warn your readers against having anything to do with these articles and ask them if they should come across any of these goods to communicate either with me or the City Sale and Exchange, Aldersgate Street, or the City Police? Thanking you in anticipation.—Yours faithfully,

C. P. GOERZ.

THE TIMES ARE OUT OF JOINT.

To the Editors.

Gentlemen,—The correspondence columns of your admirable journal last week revealed a condition of affairs in the photographic profession which would be extremely amusing if one could forget for the moment its pathetic side.

First, there was a further contribution to the ink-slinging competition between some photographic firms in Liverpool, whose incidental revelations of the methods which are resorted to by photographers—out of the class which has been spoken of as “the scum of the profession,” but of a class to which the terms “reputable and respectable” should be applicable—should be a warning to those who have any thoughts of taking up photography as a career, that if they do so outside they must expect, not the wholesome and honourable competition that is fairly general in commerce, but the most virulent antagonism and enmity of those whose true interest it is to act with and not against their fellows in the same profession.

We have all heard that amusing account of an island where the civilised inhabitants live by taking in one another's washing. Of course it is a fable; but it is no fable that there exists amongst us a community attempting to live on stealing one another's trade.

Then there is the letter from the Baptist minister, who, being a failure in his own profession, it may be, as he says, through no fault of his own, wishes to enter the already overflowing ranks of photography. Better, by far, had he learn to mend boots. It is a more peaceful, a more useful, and certainly a more honest occupation as times go. What he describes as the weakness of his denominational system is not really a weakness. It requires more than average ability to succeed, business ability and mental ability, precisely what is required to succeed in photography. It is brutal to put it this way I know, but even this brutality is justifiable if it prevent a good man taking the road to failure.

Then there is the process worker. Times are so bad that those already established have so little work that they cannot employ him. He naively asks you how he is to do that which people who have experience and every facility for the purpose cannot do; that is, get orders. Anyone who can get orders can get the work done. He, for example, is ready to do the work, but there is no work to be done, or not enough to go round.

Then there is the letter by “Ten by Eight.” He makes a legitimate complaint that his competitor in business uses as specimeus work which is not his own. To do so of course in any other business than photography would show an absence of any sense of commercial morality, but this kind of thing seems to be quite a venial offence in our honour-

able profession. But your correspondent follows on with a statement that an amateur starting in business without professional experience, can, by sending the finishing of his work out to be done, deliver to his customer results equal to, if not better than, ordinary professional work. What a pitiful admission of incapacity—photographic incapacity, business incapacity.

If your correspondent's competitor can turn out good work by sending out his finishing, and can sell it remuneratively, what is to prevent your correspondent from following the same lines?—business incapacity. If your correspondent's competitor can get his work done better outside than your correspondent can do it at home, what is the reason?—photographic incapacity.

Why is it, I wonder, that photography exercises such a baneful influence on those who practise it? That noble animal, the horse, we know, is supposed to exercise a sinister influence over the morals of those of that nobler animal, man, who associate themselves with it, but that a pursuit which would seem to be particularly conducive to a philosophical disposition should cast a blight around is inexplicable. Look at the business side of photography. A few honourable men engaged in it, but otherwise a horde of grasping savages, intent upon nothing but acquiring money, without regard to the honesty of the means employed. Look at the amateur side at our exhibitions. The same sordid struggle throughout. At the top a conspiracy for the purpose of fraudulently obtaining renown for those engaged in it. Lower down, a fierce contest for medals, not to earn them by superior merit, but to get the award by any means, legitimate or otherwise. Look at the scientific side of photography. Who have the greatest reputations; those who deserve them by their work or those who spend their time less usefully but more effectively in advertising themselves? Look at our photographic writings, volume upon volume and article upon article, supposed to be intended to teach but really merely written for pelf by writers who are in need of elementary instruction themselves. Look at our leading Society. How does it occupy itself? In carrying out its object—the furtherance of the interests of photography? O, dear no, nothing so dull and uninteresting, it is apparently regarded as of far more importance to settle who shall be president next year, and who, besides, shall share the honour of mismanaging its affairs.—I am, etc.,

A. C. B.

STUDIO CONSTRUCTION.

To the Editors.

Gentlemen,—Having in preparation a revised edition of “The Studio and What to do in it,” by my late father, H. P. Robinson, I shall be obliged if any photographers who have built studios on the plan recommended by him on page 23, or without a sloping roof, as he suggested might be the “Studio of the Future,” will communicate their experience of them to me.—Yours faithfully,

RALPH W. ROBINSON.

Redhill, November 7, 1904.

SIR CLEMENTS R. MARKHAM, president of the Royal Geographical Society, opened, on Friday last, the exhibition at the Bruton Galleries, Bond Street, of photographs, water-colour drawings, sketches, and other articles of interest brought from the Polar regions by Captain Scott and the officers of the Discovery Antarctic Expedition. There was a large attendance. Sir Clements Markham, in declaring the exhibition open, said it would enable people to realise better than anything else the extraordinary hardships and perils which were encountered by our gallant countrymen in the Antarctic regions, and would also show to them the magnificent scenery in the midst of which they achieved such great results. The very best artist who ever entered the Polar regions was on board the “Discovery” in the presence of Dr. Wilson, and the most talented photographer in the person of engineer-lieutenant Skelton. No Polar expedition was perfect unless that expedition wintered in those regions with sleigh travelling. Visitors would be able to see the methods by which the great and successful journeys were made; the sleighs, the cooking apparatus, the food, and everything else which the members of the expedition took with them, and any of those who wished to do so could have a small piece of pemmican.

Answers to Correspondents.

- *** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- *** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- W. Thorneycroft, 61, Green Lane, Wolverton. Photograph of Miss Moleseworth's Wedding Group.
- A. Wrags, 30, Barscough Street, Ormskirk. Photograph of Latham House, and Photograph of Latham Park Chapel, Latham, near Ormskirk.
- E. Ove-Thomsen, 15, Hall Gate, Duncaster. Photograph of the Bishop of Sheffield and Curates.
- G. H. Greenway, 181, Midland Road, Bedford. Photograph of Bedford Football Club.
- C. Bellinger, 4, Town Hall Terrace, Paignton, S. Devon. Photograph of Screen, and Photograph of Screen and Pulpit, Lydford Church, near Bridestowe, Devon. Two Photographs of the Interior of Woodbury Parish Church, near Exeter, Devon.
- J. Javrett, High Street, Keynsham, Bristol. Photograph of the Interior of Keynsham Parish Church, and Photograph of the Font, both decorated for Harvest Festival.
- J. H. Partridge, Park Green, Macclesfield. Photograph of Buffalo Bill.
- T. R. Hammond, 1, Rose Hill Street, Conway. Two Photographs of a General View of Conway.
- J. W. Wheeler, 4, North Street, Horsham. Photograph of A. Shrubbs.

CHANGED TONES.—"ANIS" says: "The enclosed prints have gone red by being exposed in a showcase. Is it any fault of manipulation or normal? What is your opinion of the work for 15s. per dozen?" In reply: Prints made from weak negatives and lightly toned are liable at times to undergo a change in colour by long exposure in showcases. The work seems good enough for the money.

SENSITISING ALBUMEN PAPER.—"ALBUMEN" asks: "Can you oblige me by publishing how to sensitise albuminised paper?" In reply: This appears to be a repeat of your query which we replied to in our issue of the 21st ult., to which we refer you. If you know nothing of silver printing, which we assume is the case, we should advise you to get a treatise on the subject—say "Art and Practice of Silver Printing," by H. P. Robinson and Captain Abney.

FADED PRINTS.—"E. W. B." asks: "Can you give me any formula that will restore old, faded albumen and P.O.P. prints, as I very often get them for copying when they are nearly faded away?" In reply: We know of no successful method of restoring faded silver prints. More than one method at times has been suggested, but in our hands they have not proved of value. Prints on albumen paper that have gone yellow, if they were toned with gold, may have the yellow tint removed by treatment with a dilute solution of bichloride of mercury, but that will not restore any detail that has disappeared.

RECOVERY OF ACCOUNT.—"ONE AT A LOSS" writes as follows: "I should feel greatly obliged if you could tell me how to act in this matter. Two months ago a builder called at my studio and got me to photograph some houses for him W.P. size. I submitted a finished proof, which was approved. An order for six prints was given, which were never called for. I wrote about the matter, but got no answer. The party lives twenty miles from here. Your advice will greatly oblige." In reply: Send the prints ordered to the builder's address and demand payment for them. If not made, promptly sue in the County Court.

SPOTTY PRINTS.—"YELLOW SPOT" asks: "Could you kindly give your opinion as to cause of yellow spots showing on enclosed print? The photo has been finished about three years, spots appeared a few months ago. These markings have appeared on other photos mounted on similar cards, but photo finished with same batch, but on different mounts, are now good as when finished. Do you think the mounts are to blame?" In reply: Spots such as these may be due to ferent causes, all of which are attributable to the manipulations. We see no reason to suspect the mounts, but if you are suspicious of them why not send them to an analytical chemist for examination?

STUDIO QUERIES.—"EMILE" says: "(1) Enclosed you will find plan and elevation of proposed studio. On the north side is where I shall have my side lights, which will be 5 ft. from ground. You will see by elevation that I shall have also 9 ft. by 3 ft. side-light on top of the wall, and also a 3 ft. 6 in. by 2 ft. 6 in. light on the door and also a fanlight above door. By referring to plan you will see pencil lines indicating light, which will be 6 ft. by 4 ft. Do you think that will be sufficient light with the aid of reflectors? (2) If I place the scene on wall on north-west side, and place the camera at east corner, I shall be able to get about 7 ft. between lens and scene. Should I be able to purchase a half-plate lens capable to photograph sitters for carte-de-visite full length? Do you think it would be advisable to lower the north wall have a little more side light? I trust diagram is discernible. In reply: (1) We must confess that the sketches, to us, are a little "mixed," but so far as we can make out the studio will be very small if you require it for professional work. It will be light enough for so small a place. (2) No, you certainly will not. (3) Yes, by a couple of feet.

STUDIO.—BOOK WANTED.—A LADY OPERATOR asks: "(1) Would you very kindly look over the enclosed plans (which I do not need returned), and tell me if you think they would make a good workable studio? Would you also advise me as to what would be best for the slant of the roof. (2) Can you advise me in the choice of a book on the theory of photography—one that would give me a good, simple explanation without my having to sit up all night with a wet towel round my head? Your article on this subject in this last issue of the "Journal" made me determine that at least one professional is not going to be accused of ignorance even by her own conscience. I am in absolute darkness, as I have learnt, picked up, and also used my (what is commonly called) "gumption" but want to have it in black and white." In reply: (1) The studio as shown in the sketch would be a very good one. The glass need not come down so near to the floor by a foot. A similar angle to that shown in the sketch will do for the roof, but a little more slope would perhaps be an improvement. "Instruction in Photography," by Abney, or "Science and Practice of Photography," by Chapman Jones, are both good books.

*** NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies, and will number 1,612 pages, thus constituting the volume the largest yet published.

The following are some of the important features of the forthcoming volume:—

1. The frontispiece will be a portrait study specially produced for the Almanac by Mr. Furley Lewis (Medallist at the Royal Photographic Society's Exhibition, 1903).
2. The first editorial article, which deals with "The Present and Future Position of Photography," discusses the probable growth and expansion of all branches of modern Photography.
3. The second editorial article supplies a succinct illustrated history of the BRITISH JOURNAL OF PHOTOGRAPHY and the Almanac ever since their foundation.
4. Important articles and papers by the following, amongst many other well-known photographic writers, are included in the volume:—

Abney, Sir W. de W., C.B.	Dormer, J.	Hartmann, Dr. J.	Nelson, E. M.	Salisbury, J. W.
Baker, T. Thorne.	Duncan, F. Martin.	Henderson, A. L.	Neuhanss, Dr.	Salmon, P. R., F.R.P.S.
Baldock, J. H., F.C.S.	Dunmore, Edward.	Hepworth, T. C.	"Ons."	Selby, H.
Barker, J.	Dunmore, G. H.	Hett, Charles Louis.	Payne, A., F.C.S., F.R.P.S.	Slater, P. J.
Bentley, B. F., M.A., F.L.S.	Everitt, Philip.	Hodges, John A., F.R.P.S.	Perkins, Rev. T., M.A.	Smith, J. H.
Bird, J. J. S., B.A.	Foxlee, E. W.	Joly, Dr. J., F.R.S.	Pike, J.	Sutton, C. T.
Blasbroek, G. Van.	Gamble, William.	King, Horatio Nelson.	Piper, C. Welborne.	Tilfor, J.
Boias, Thomas, F.I.C., F.C.S.	Goodchild, Rupert.	Leisk, J.	Procella.	Wall, E. J., F.R.P.S.
Brosig, P.	Gower, H. D.	Lockett, A.	Rheinberg, Julius.	Wallace, Robert James.
Brown, G. E., F.I.C., F.C.S.	Graves, Frederick.	Mills, Edmund J., D.Sc., F.R.S.	Richards, T. W.	Walmsley, W. H.
Channon, H. J.	Hackett, J. T.		Rohr, Dr. Moritz von,	Watkins, Alfred.
Clifton, Edgar, F.R.P.S.	Harris, Geo. T., F.R.P.S.		D.Phil.	Valenta, E.

5. Numerous illustrations, including Portraits of many Celebrities in the Photographic World.
6. An exhaustive Review of recently introduced Photographic Apparatus.
7. Sections devoted to Practical Points; Epitome of Progress during 1904; Formulæ; and a great mass of Miscellaneous Information.

EX CATHEDRA.

The Dublin Convention.

The Dublin Convention will be held in Trinity College, the authorities having, at the instigation of the President-elect (Professor Joly), generously placed that portion of the building known as the Engineering School, with its lecture rooms, museum, etc., at the disposal of the Council for the week commencing July 10, 1905. Trinity College is one of the most interesting buildings in Dublin, and was founded by Queen Elizabeth in 1591. Several capital pictures may be secured in and around the Quadrangle, which is adorned by Foley's fine statues of Oliver Goldsmith and Edmund Burke, and the handsome Bell Tower, erected by the late Primate Beresford at a cost of £10,000. As the College will be open to members of Convention only, arrangements are being made to hold the Trade-Exhibition of Pictures and Apparatus in an adjoining building, which will be free to the public as usual.

* * *

Lenses for Post Card Pictures.

A correspondent, whose letter we reply to here instead of in the usual column, as the information may be of use to others, writes to the following effect:—"I wish to take negatives for post-cards the full size allowable. But when I use my half-plate camera and lens the angle included is too small. If I get a 5 by 4 lens it will not cover the $5\frac{1}{2}$ in. allowed by the Post Office. What lens shall I get to cover the $5\frac{1}{2}$ by $3\frac{1}{2}$ and yet include a fair angle?" Now, if we measure the diagonal of a picture 5 by 4 and that of one $5\frac{1}{2}$ by $3\frac{1}{2}$, we shall find that the measurements are practically the same. Consequently, any lens that will cover a 5 by 4 plate will equally as well cover one $5\frac{1}{2}$ by $3\frac{1}{2}$, while of course a wider angle, on the base line, will be included. The field of a lens is a circle, and any oblong, no matter what its proportions, that can be cut from that circle will be covered. For example, any lens that will cover a 10 by 8 plate will cover equally as well, or rather better, one $11\frac{1}{2}$ by $6\frac{1}{2}$, or 12 by 6 in., while as a matter of course, a much wider angle on the base line will be included. This fact does not appear to be so well known to many as it should be.

* * *

Ilford and German Injustice.

In another column we publish the translation of an account which has appeared in some of the German photographic newspapers of an action brought by the Westendorp and Wehner Company against Ilford, Ltd. The action took place in Cologne. It is a fact, which almost every photographer knows, whether here or in any other civilised country, that the Ilford Co.'s trade mark has been for many years a steamer bearing the flag inscribed "Ilford." It appears that a trade mark was registered in Germany by the Westendorp and Wehner Co. in 1902. This mark is described in the proceedings as a steamer in a circular frame, and, according to the account, it is to be inferred that the Westendorp and Wehner Co. were exporting plates to China in boxes labelled with tickets bearing two of these marks and the inscription "The Ilford Empress Plates." It is moreover stated that the Westendorp and Wehner business has been established for a number of years at Ilford. From this description, which implies that the Westendorp and Wehner plate bore the name of one of the "Ilford" well-known brands, we think there is fair ground to believe that an imitation of the "Ilford" brand was intended. The Ilford Co. supplied the American Trading Co. with plates, for export to China, bearing a label with the inscription, "The Ilford Empress Plates," and two circles enclosing a sailing ship. It seems to us that the retaliation was fair sport. If the Westendorp and Wehner

label was a colourable imitation of the Ilford, what be the possible defence for it on the grounds of commercial morality. If the Westendorp and Wehner dry plates, which are exported to China, are made at Ilford, cannot the Company be sued by the Ilford Co. upon similar grounds?

* * *

Note on a Property of Lenses.

Under this title a paper, by Dr. G. Allan, was read at a recent meeting of the Physical Society that it may be of interest to summarise for these pages, bearing in mind that it does, on a comparatively novel method of determining the focus of a lens. A well-known method of testing the concavity or convexity of a lens is that of holding the lens at arm's length and moving it from side to side or up or down; it will be seen while looking through the lens that the image will move in the same direction as the lens when the latter is concave, and in an opposite direction with a convex. If a microscope be used for viewing instead of the naked eye, the same phenomena occur. If the division marks of a scale be looked at through a lens of considerable focal length, as the lens be at the same time moved across the field of vision the motion of the lens appears far to exceed that of the image, and the flatter the lens, and the nearer it is to the scale, the greater this disparity. Dr. Allan shows that the focal length of a lens can be expressed as the product of the distance from the scale to the lens and the magnification, the magnification being defined as the ratio between the displacement of the lens and the displacement of the image. Examples of the method as applied to three lenses were given in the paper. In the ensuing discussion, Mr. T. H. Blakeley pointed out that the distance required was not that between scale and lens, but between scale and the first principal point, a difficulty that could be overcome, he said, by making two experiments with different distances between scale and lens.

* * *

A New Meteorological Station.

A new observing station for London has just been established, under the auspices of the Meteorological Council, in St. James's Park. It is situated in an open spot a few yards from the railing bordering on the Horse Guards' Parade. It is equipped with a set of thermometers and two rain gauges, one of the ordinary kind and the other a self-registering one. The latter records on a sheet of paper, which is renewed daily, the occurrence of rain at any hour of the day or night, and the rate at which it falls. On one of two screens close by are placed automatic records of bright sunshine, of rainfall, and the temperature for the previous twenty-four hours, all made at Westminster. On the other is placed copies of the latest weather charts and forecasts prepared at the Meteorological Office. The information thus displayed in the Park will doubtless prove of interest to a large section of the public—particularly if one may judge from the number of people who stop to see the latest weather charts shown in the doorway of the Meteorological Office in Victoria Street. When we were in Munich a year or two ago we saw in the Maximilian Strasse a meteorological station somewhat similar to the above. It contained a self-recording barometer, a self-recording thermometer, hygrometer, etc., showing the fluctuations of the previous twenty-four hours, and it attracted great attention from the passers-by—almost every one seemed to consult it. It would be of great interest to a large proportion of the public if similar stations were established in some of the open spaces of London, say, such as Trafalgar Square, opposite the Royal Exchange, and the like. The cost would be but small, and the up-keep quite nominal, namely, changing the records every morning, or night. Of course,

London space is valuable, but the affair we saw in Munich did not take up more room, if so much, as an ordinary drinking fountain.

Disappearing Blondes. Some considerable time ago there appeared in the pages of a popular magazine—*Cornhill*, if we remember aright—an article founded on some investigations that had been carried out by a German philosopher, and entitled, "On the Probable Future Extinction of Blue Eyes." It was shown as the result of observations over an extended period that the proportion of blue eyes to dark was gradually decreasing, and to such a marked extent as to lead to the deduction that eventually there would be no more blue-eyed people in the world—the European world, at any rate. The same idea has been utilised by an American scientist, but he has dealt with blondes generally and not a particular case of blondes. Professor Mason, Anthropologist at the Smithsonian Institution at Washington, has devoted his investigations to the prevalence of girls with fair hair, and these, he states, are disappearing so rapidly that he anticipates the next six centuries will see the end of the blondes. He accounts for this gradual decrease by stating that they possess a lower vitality, are shorter-lived, and more susceptible to the evil effects of urban life. Any advantage that the photographer will gain will not be participated in by the present generation, who will have to be content with the usual modes of counteracting the photographic difficulties that connect themselves with the photographing of fair and red-haired sitters. As we need not observe, the hair is by no means the chief difficulty; wrinkles on the face usually accompany light hair, especially that of the "red" type. Of course this simply means work for the retoucher. As for hair, we know of one professional photographer who uses powder of three different tints, according to his subjects, for bringing out a suitable effect on the negative without need for retouching. Blue eyes can only be treated correctly (failing the practically excluded isochromatic plate) by a special arrangement of the illumination.

Water Absorption by Wood. The user of photographic apparatus is specially liable to troubles arising from the absorbing powers of wood, which takes up atmospheric moisture so readily. Thus he receives, say, a new outfit of camera and slides, which work "dead true," as the phrase goes. He puts the apparatus away in a dry place, and, perhaps, does not use it for a month or two. He then finds the dark slides tight and difficult to insert, while the shutters are annoyingly tight and difficult to withdraw or close when opened, all through the fact that moisture has been absorbed with a consequent slight swelling of the wood. In course of time he finds the backs of his printing frames liable to warp, especially with the larger sizes, while the minor evils of cupboard doors sticking, and so on, are numerous enough at winter time. A good coat of French polish or of oil-paint laid upon dry wood will prevent much, but not all, of this trouble, for there will usually be some portion of the woodwork which cannot be polished or painted, and thus the absorption and swelling begin, especially when the hygrometric conditions of the atmosphere are unfavourable. The only remedy, or, rather, prevention, is to have apparatus which, at any rate to start with, is free from moisture—i.e., commercially "dry"—and then to see that it is always kept with its polished or painted surfaces in good condition and removed when damaged. According to M. Deploy, wood kept for several years in a dry place still retains 15 to 20 per cent. of water, and when it has been thoroughly desiccated will, when

exposed to air under ordinary circumstances, absorb 5 per cent. of water in the first three days, and will continue to absorb it till it reaches to from 14 to 15 per cent. as a normal standard. It will thus be seen how easy it is to complain of "damp wood" in apparatus when not an atom of foundation exists for the charge.

Testing Copper Sulphate.

The use of sulphate of copper for the toning of bromide prints has increased to quite a considerable extent during the last year or two, the process introduced by Mr. W. B. Fergusson having been followed by the other methods, in which the print is bleached in a solution of copper chloride. This latter salt is usually prepared by double decomposition from the sulphate, and therefore any impurity in the common source of the toning preparations will be injurious in both cases. In Fergusson's process especially the presence of iron is likely to interfere with the tones obtained, inasmuch as ferricyanide of potassium is the other active constituent of the toning bath, and the blue-coloured compounds which it forms with iron are well known. In the case of the bleaching process also the presence of traces of iron may lead to irregularity from the tenacity with which paper retains iron salts. The subsequent application of the darkening solution of sulphide would then give rise to the dark-coloured ferrous-sulphide. It is useful, therefore, to have a ready and sensitive test for iron in copper salts, such as is recommended by Grouzel in the "*Journal de Pharmacie et de Chimie*." A 10 per cent. solution of the copper sulphate is prepared and excess of sodium thio-sulphate (hypo) added so as to give a colourless liquid. Potassium ferro-cyanide solution is then added, and gives in the presence of iron a pale-blue precipitate which becomes dark-blue after a time. In the case of copper free from iron the precipitate is greyish white. A further test can be made with hypo alone. Equal volumes of 10 per cent. solutions of the copper-sulphate and the thio-sulphate are mixed together and allowed to stand for some time. In the case of a pure sample of copper the well-known Lenz's Salt is formed as pure yellow crystals on the sides of the test-tube. If iron be present the colour of this precipitate is noticeably modified by an ochre-yellow deposit or basic ferric-sulphite. The two tests are specially convenient to photographers, as they require only reagents, which are on the shelves of every dark-room.

* * *

Alcoholic Colours.

A short time ago the photographer had little interest in questions of colour, except, perhaps, that he found it useful in his work to issue a few hints in print to his sitters in order that they should avoid those tints which photographed dead black, and so put the wearers into involuntary mourning. But now everything to do with colour interests him, and a fresh addition to the long list of anilines will cause him to make inquiries as to its particular virtues. People used to talk about the seven colours of the rainbow, but their number is no longer confined to seven, but rather to seventy times seven, and we are not quite sure, without the means of reference at hand, whether that aggregate would include all the tints which are now at the command of the experimentalist. To find different names for all these little bits of the solar spectrum was as difficult a business as it was to Adam to find appellations for the beasts of the field and the fowls of the air, but it had to be done. When colours were few the names were borrowed from familiar things, so that we have among the old names "rose" pink, "sky" blue, "lemon" yellow, and so on. No one raised any objection to this sensible course. But people—or at any rate some people—are more particular now, and we find a worthy abstainer

protesting in the columns of a religious periodical that the hateful word "champagne" has been applied to a new colour which approaches in its tint that effervescent beverage. To quote the immortal words of W. S. Gilbert, "How very, very pure this pure young man must be!" It takes away the breath of the ordinary man, the common sinner, to think that there are beings on this earth so superlatively good that with them "champagne" must be numbered among the naughty words. Let us try to live up to the same ideal by carefully abstaining from calling anything claret colour, or the colour of pale sherry, or mentioning the compromising fact that wine is sometimes red. Happily we can do without these vulgar and harmful references by studying the list of colours issued by the aniline manufacturers. Thus we can without a blush use the terms eosine, erythrosine, and phloxine for reds, or, to be more precise, we can describe them as alkali salts of bromine and Iodine compounds of fluorescëin and of dichlorfluorescëin.

* * *

English Dry Plates. In the "Photographisches Wochenblatt," Herr Gaedicke returns to the paper by Mr. S. H. Wratten on the manufacture of dry-plates, of which he published a translation. He takes exception to the remarks—"The home product of dry-plates is far and away superior to the Continental makes"; "in that country (Germany) there is not a plate factory of any magnitude"; "English plates are preferred." With all deference to Herr Gaedicke's opinion, we venture to think that much may be said in defence of Mr. Wratten's statements. Herr Gaedicke asserts that good dry-plates are now made all the world over, and that English plates are not one jot better than the Continental. We answer: Have you a plate equal in speed to the Ilford Monarch? With regard to Herr Gaedicke's statements as to orthochromatic plates, we would also reply, since the best-known plate in Germany—the Perotto—is instanced, that on page 775 of this paper, this year, he will find the report from one of his own countrymen of a comparison between the Barnet Orthochromatic Plate with another, which, to our personal knowledge, was one of Perutz's Perotto Plates. We have the negatives before us. Moreover, the price of the Barnet plate is about half that of the Perutz plate. We would remind Herr Gaedicke that price must also count. Mr. Wratten's experience agrees with our own. We have introduced English plates to German photographers, and after trial they have regretfully acknowledged that they prefer them to those of German manufacture. Regarding the extent of the manufacture of plates in Germany, we would refer Herr Gaedicke to the first paragraph we published in our issue of January 24, 1902. These are the latest figures at our disposal, but we doubt if those of this year differ materially. The entire German exports of photographic requisites were then £550,000. Apart from papers and lenses, the value was £270,000, from which a very considerable deduction has to be made for chemicals and cameras. For the present case we will assume these to represent only £70,000. As two-thirds of the entire German plate production is exported, the entire output must, consequently, be about £300,000. The figures upon which these calculations are based were published in Herr Gaedicke's own paper. If we remember that there are a number of German plate-makers, can it be doubted that Mr. Wratten was not exaggerating seriously. The question of magnitude is a relative term, some idea of which may be gathered from the fact that nett profits of the Ilford Company in 1901 were £53,700. What must have been the output of this one firm alone?

THE IDEAL RETOUCHING DESK.

CURIOSLY enough, while all around them photographic apparatus of every description has been improved or modified almost out of recognition, retouchers are content to work patiently on with the same old pattern of desk which did duty in the early dawn of photography. Speaking generally, the retouching desk of to-day may be summed up briefly as consisting of a hinged flap with square or circular aperture, attached to a box-like base, possibly containing a drawer, with, overhead, another hinged flap forming a screen from the light when in use, and a lid for the box when closed. The reflector and side flaps are secondary additions which, to judge by their apparent lack of adaptability to their purpose, are thrown in as an after-thought.

Now, at the best, retouching is a none too healthy occupation. It would certainly seem, then, but simply common sense to inquire critically how far the existing form of desk is consonant with the requirements of hygiene, and, secondly, whether it meets the practical needs of the retoucher to the extent that might be expected.

The convenience of the present model may be at once admitted. As regards portability and readiness of erection it leaves little to be desired. But when inquiry is instituted as to its character from a medical and sanitary standpoint, the answer is hardly so satisfactory. In the first place, sufficient attention is not paid to the necessity of adjusting the height of the desk to obviate stooping on the part of the worker. In a good many cases, of course, this difficulty is intelligently overcome by choosing a table of suitable height on which to place the desk, or perhaps by inserting books or small boxes underneath. Frequently, however, the retoucher, ignorant or possibly careless of the harmfulness of continual stooping, does not attend to the matter. That such a position, constantly adopted, or work requiring steady application, and in a more or less stuffy atmosphere, is decidedly injurious there can be no manner of doubt. We have known consumption and other chest affections induced by this cause alone. The ideal retouching desk, then, should apparently possess not only a means of adjusting the height of the negative, but also provision for raising or lowering the whole contrivance to any convenient height.

Another matter of urgent importance is the question of ventilation. It is bad enough, and unhealthy enough, to have to work in the semi-darkness which seems to be considered indispensable, but there is no valid reason why air also should be excluded. Yet in how many cases the retoucher is seen surrounded by stuffy hangings of heavy black cloth, draped clumsily over the desk, and with every air inlet closed on three out of four sides. Worse still, perhaps, an insufficiency of daylight compels the employment of a paraffin lamp, whose close proximity converts the atmosphere under the hood of the desk into the faithful similitude of a miniature Inferno. The retoucher pines away at full pressure under such conditions for the greater part of the working day, emerging finally from the heated and vitiated surroundings into, it may be, the chilly air of a winter's evening. Need one anticipate the probable consequences?

The remedy for this state of things is easy and obvious. Attention should be paid to the provision of suitable apertures at various parts of the desk. The top, too, instead of being wood, may consist of several thicknesses of soft light, open fabric, pervious to air, which, by means of rings attached to a stout wire frame, can be allowed to hang over at each side in the manner of curtains. This is no means a new idea, but such an arrangement is, unfortunately, seldom met with. The ventilation of the room used for retouching should also receive its proper share

voice, so that the slightest sense of stuffiness or closeness is rendered impossible.

The angle of the retouching desk is commonly at too great a slope, involving not only stooping, but a certain strain on the eyes. The adjustments should be such as to allow of the negative being worked in a practically upright position, on a level with the eye. In this respect sufficient regard is not paid to the proper balancing of the arrangement, which, unless inclined to an undesirable angle, is morally certain to topple over in front. It would seem, therefore, to be a desideratum that the panel supporting the negative should be capable of clamping or fastening at any desired slope, even leaning towards the retoucher if necessary, while the base of the desk should be sufficiently heavy to prevent any tendency to overbalancing. Some suitable means of firmly gripping the negative should, of course, be provided; but on this point there is little to be said, since there are already many excellent ways in which this may be accomplished. In fact, it might be stated with considerable truth that greater regard has been paid to the safety of the negative than to the comfort or health of the worker.

We come now to yet another important factor—that of lighting. It is a recognised truth that retouching, in many cases, causes serious injury to the eyesight—often to such an extent as to compel the unfortunate artist to abandon what is practically his or her only means of livelihood. On the other hand, we find a large number of workers who not only emphatically deny any ill-effects in their own cases, but even go so far as to claim positive benefit to the eyesight, which, they say, has been strengthened and rendered keener. This apparent contradiction resolves itself into a simple question of initial fitness for the task, and the employment of certain prescribed precautions. Where the eyesight is in the slightest degree weak to begin with, it is the height of folly to embrace retouching as an occupation. By weakness is not meant any slight degree of short-sightedness, involving the wearing of glasses, or trivial idiosyncrasies of that nature, for very often short-sighted people are found to have peculiarly keen vision. What may be defined as a bar to successfully taking up retouching is that weakness of sight which feels fatigue at any prolonged exertion, or finds difficulty in executing the work for any length of time.

Assuming, then, that the retoucher's eyes are in good condition at the commencement, what means are to be adopted to keep them so? A little consideration will show that two things in particular are to be avoided—glare and strain. The light should be so managed that, on the one hand, unnecessary brightness and glare are removed, while, on the other, the worker finds no difficulty whatever in recognising every portion of the negative which requires treatment or in applying the requisite touches. In the majority of cases it will be found that mischief is done to the eyes rather by an excess than an insufficiency of light, since the latter is more readily noticed and remedied. It is advised that, when possible, the light should be obtained by reflection from a dead white surface, such as a sheet of note-paper, since this gives an illumination singularly free from glare. Light reflected from a mirror on to a sheet of ground glass fixed behind the negative is, perhaps, the next best thing, while the mirror alone is undoubtedly the worst.

The great disadvantage of daylight from an oculist's point of view is its lack of uniformity, which obviously involves eye-strain from time to time. Indeed, where this can be done, it is a good plan to work only by artificial light. Although at first more difficult to work with, the eye soon becomes accustomed to the peculiarities of artificial illumination, and can thenceforth enjoy the advantage of a lighting free from violent and disturbing fluctuations.

The one objection is, of course, the expense, though this is less than might be imagined.

There has been a good deal of disagreement as to the best artificial light for retouching. The majority of workers would probably agree that a good duplex burner paraffin lamp, used with ground glass and tissue paper as diffusers, is difficult to surpass. When this is employed, extra attention must be paid to ventilation, as before stated. It is sometimes feasible to place the desk close against a small opening between two rooms, arranging the lamp behind the opening. The worker is then entirely removed from any heat or fumes. The incandescent gas light, convenient as it undoubtedly is, hardly seems suited for retouching, though some workers find it very acceptable. The incandescent electric light is strongly recommended in many quarters, and must certainly be considered the best from a hygienic point of view, since there are no products of combustion. A distinct drawback to this, however, is found in the impossibility of regulating the amount of illumination, though this may be largely remedied by interposing different thicknesses of tissue paper, ground glass, and other media.

Given a suitable illuminant, then, it should be the retoucher's cue to avoid exposing the eyes either to excessive glare or the strain of working in a feeble light. This, of course, involves constant adjustment of the light to the negative as the density of the latter varies. The trouble involved is slight, and well repays itself in ease and facility of working, besides removing the potent causes of future trouble.

In conclusion, although there is difference of opinion on this point, it is strongly advised that those parts of the negative not being worked should be blocked out by means of a brown-paper mask. In view, also, of the fact that darkness is unfavourable to health, it is suggested that the room be kept as light as possible, consistently with the proper screening of the negative. So long as an excess of direct light does not fall on the film, a surprisingly large amount may be allowed all over the room. In addition, an occasional resting of the eyes will be found not only highly beneficial, but conducive to a broader and better style of work.

COLOUR in Character.—Experiments numbering over three hundred, and conducted over a term of three years, have convinced Dr. J. Stenson Hooker, of Nottingham Place, W., that the N-rays emitted by the human body differ in colour according to the character and temperament of the person, and he gives the following curious particulars in a letter to the "Lancet":—"Rays emanating from a very passionate man have a deep red hue, says Dr. Hooker; the one whose keynote in life is to be good and to do good throws off pink rays; the ambitious man emits orange rays; the deep thinker, deep blue; the lover of art and refined surroundings, yellow; the anxious, depressed person, grey; the one who leads a low, debased life throws off muddy brown rays; the devotional, good-meaning person, light blue; the progressive-minded one, light green; and the physically or mentally ill, dark green." "I know perfectly well," adds Dr. Hooker, "that these statements will be received by many with an amused smile of incredulity, as many other so-called 'discoveries' have at first, but I also know perfectly well that sooner or later they will become accepted facts. Nor is there anything remarkable or unreasonable in all this when we consider that man has been thousands of years (Max Müller is my authority) in evolving his colour sense to its present point. There is no Sanskrit word the meaning of which has any reference to colour; Xenophanes knew of three colours of the rainbow only. Some 15,000 or 20,000 years ago man was only conscious of one colour; later red and black were distinguished; still later, yellow, then green. As our senses become more refined surely we shall evolve the power of detecting more refined hues. We have not yet reached the point of finality in rays."

JOTTINGS.

THE last smoking concert of the Photographic Salon, which took place more than a fortnight ago, supplied opportunity for some badinage at the expense of the writer of these lines. I am said or supposed to have written the epitaph of the Salon, and to have that gem of memorial literature stowed away in a secret drawer, where it reposes under a thick layer of dust. It is a dangerous thing to make a quotation without verifying it. My recollection of the matter (and I ought to know something of it) is that in the course of a controversy in these columns, some ten or a dozen years ago, with Mr. Alfred Maskell, that gentleman ironically twitted me with my "services" to the Salon. The retort was that those services were uncompleted: I had yet to write the Salon's epitaph. It is still unwritten, but I live in hopes of an early perpetration of the effort, for I see that attempts are being made to bring about a reconciliation between the Salon and the Royal. If success should crown the movement, what a fine opportunity it would give me of casting my epitaph in the form of a new version of the parable of the Prodigal Son! Mr. H. Snowden Ward, who is the Apostle of Fusion, presumably makes the suggestion in all seriousness. That being so, I do not doubt that he will secure a considerable following amongst the more modern "pictorialists," who find it difficult to perceive the necessity of two autumn exhibitions of photographs held simultaneously within a few score yards of each other. Those persons outside the Royal who complain so much that the interests of pictorial photography are not properly looked after by the society, would be surprised to know how delighted many non-pictorial members like myself would be to have the whole business settled out of hand once and for all.

The photographic profession has not responded to the invitation to resuscitate the old Benevolent Fund or start a new one, and unless the P.P.A. can do something towards rousing its members in the good cause, failure must once again be placed to the credit of the philanthropic few who delude themselves by thinking it the easiest thing in the world to help a body of men who will not help themselves. So little esprit de corps is there amongst photographers, that even the P.P.A. itself is hampered in its work for lack of support not only by outsiders but by its own members. You would think that such a scheme as that which was printed in the JOURNAL the other week relating to the examination of assistants would call forth a perfect flood of commendatory or critical correspondence in these pages. Not a bit of it. But when cigarette and soap people enter into temporary competition with photographers, oh! then the fat is in the fire with a vengeance. Hundreds of letters are written to the Press, heated meetings are held, and appearances point to the probability of "something being done" at last. Something, it is true, has been done by the P.P.A. during the three and a half years of its existence, but the frothiest and blatest of those who clamoured for its foundation have subsided, do not attend its meetings, and now skulk behind a curtain of indifferentism. Still, all honour to the Committee of the P.P.A., a hard-working band of conscientious men who get through a great deal of useful administrative labour, unthanked and unrewarded. The status of photography as a profession or a business, however, will never be raised in the public estimation until there is more cohesion, more combination, and greater unanimity of ideal amongst those who choose a difficult and harassing, but nevertheless beautiful and interesting, method of graphic expression as a means of earning a daily crust.

I am pleased to see that thus, early arrangements are in progress for making the Dublin meeting of the Photographic Convention of the United Kingdom next July a great success.

It is an open secret that in 1906 Southampton will be the scene of the gathering; so that two very happy times are store for the members of this flourishing peripatetic photographic institution. May I throw out a suggestion with regard to the evening meetings? It is that the paid services of first-rate lecturers be secured. The hack and hackneyed photographic subjects which figure in the yearly programmes of photographic societies all over the country are of place at an avowed holiday gathering, whereas men of the eminence of Sir Robert Ball, Mr. Kearton, and others might be named, would prove great attractions, not only to Conventioners, but also to hundreds of their temporary hosts and hostesses. It is time the lighter side of the Convention were developed. If a dinner and a garden party, why not a ball? Or is it too hot for that sort of thing in July? I am not a dancing man, so cannot say. Much has been made of the fact that the Convention has a large sum of money in hand. This is a testimonial to the excellence of its business management. The lecture suggestion, if carried out, would involve inconsiderable outlay, so that the hoarding-up process would be arrested, or at any rate checked. It is quite evident that the Convention, which reaches its nineteenth year of existence in 1905, has entered upon a very vigorous phase of its career and bids fair to survive to a green old age. I wonder what the scene of its meeting will be in 1907, when it attains its majority! May I suggest the Isle of Man, which, like Ireland, has not yet had the honour of a visit from the present writer?

THE St. Louis awards to British photography have on the whole been well received in this country, although, of course, there are some surprises and several disappointments. An American exchange, "The Photo-American," just to hand, contains a reproduction of a group of the international jury whose names no doubt will interest many of my readers. They are J. Poulton; Curtis Bell, F. Dundas Todd; I. von Reden, G. M. S. Stein, W. Zimmermann, C. M. Kurtz (Department of Fine Arts), S. Lazarenech, J. Craig Annan, M. Lumière and M. Gaumont. Poulton, Von Reden, and Lazarenech are names to me. Bell and Zimmermann are prominent American Secessionists, and Todd is, of course, the hustling editor of "The Photo-Beacon."

American "Photographic Politics" (I have been credited with the invention of the phrase in inverted commas) appear to be mixed; at any rate, they are more difficult to an outsider to comprehend than I imagine are our own by onlooker from a distance. I understand from quite independent sources that the management of the photographic section at St. Louis left much to be desired. This is generally the way with comparatively small sections in these huge international exhibitions. I remember at Paris in 1900 much the same sort of thing was experienced. Paris, by the way, is already talking of another great exposition to be held a few years hence. Attempts that have hitherto been made to secure separate pavilions or palaces for pictorial photography at these universal exhibitions so far completely lack successful results. But we are moving quickly in such matters, and shall move with even greater rapidity in the future, and it would not surprise me to find that when the fair city on the Seine again invites strangers from all nations to become its guests, the world's pictorial photographers will have achieved their ambition. As to the establishment of a Royal Photographic Academy, that will be only a step.

The report of the St. Louis National Photographic Convention takes up over forty pages of "Wilson's Photographic Magazine." It seems to have been a busy and wordy week. The only novel address was one by Mr. W. G. South on "Color Photography," who in the course of a fragmentary sketch

his subject, stated that he had invented a process for producing prints in colours which he called "Solgram." Says Mr. South:—"For years I have been convinced that the three colours—yellow, red, and blue—had some particular office in the world of art except tinting objects, and I invented the "Solgram" to prove my theory (namely, that red was the base and warmth of a picture, blue was the great drawing master, giving detail, shadow, and form, and yellow gave to our work light and life). I reasoned with myself thus: If red is the base, it should be placed first upon our paper (or suitable substance), and as its office is simply to give warmth, tone, or colour, it need not be sharp and wiry; therefore, the old gum bichromate pigment process would suffice, with the advantages that the pigment could be chosen for permanency, and also that by reason of its colour the print, upon which a surface would be visible, doing away with actinometers, etc. After printing and washing we would obtain a beautiful crimson picture." And so on. Mr. South's reasoning as to the "offices" of red, yellow, and blue is certainly original. His "invention" seems to consist of a mixture of gum bichromate printing and the Koenig process. Please oblige with fuller details, Mr. South.

The erudite Mr. South, who had a display of "photographs in natural colours" at St. Louis (I quote his own description), is not kind to the various systems which antedate his own somewhat ambiguous and mystical method. Mark him: "So far as negatives for producing colour photographs are concerned, every desirable quality has been obtained. But, as I have said, we have no colour photographs. If this is true, then what have we? Why, we have tri-colour photo-engravings, the pictures from which cannot be produced without excellent printing presses and equally excellent printers. We have lantern slides and colour transparencies, which are beautiful, but they are not photographs. We have physical prints from dyed or stained positives which are not permanent, and are messy and dirty things to handle, and they are not photographs when finished. Now and then a photographic print is made by superposing three carbon prints or by fading out unstable dyes, but such methods are not of any commercially practical use." Will some one explain to me why it is that whenever your half-educated dabbler in colour photography "invents" some empirically mongrel process of making tinted prints he must go out of his way to show his ignorance of the main subject by passing wholly absurd and irrational comments on the work of those who have preceded him? If a trichromatic transparency is not a photograph, Mr. South, what on earth is it?

Cosmos.

Mr. W. Towle, the manager of the Midland Hotels, kindly sends us an illustrated brochure dealing with the tariffs, etc., of these well-managed institutions.

An Amusing Incident.—Hand camerists and others who were anxious to obtain portraits of the British Ambassador in Germany (Sir Frank Lascelles) had ample opportunity of securing them at Potsdam one day last week. It occurred this way. After the luncheon at Potsdam, to which Sir Frank Lascelles was invited by the Emperor, on the occasion of the birthday of King Edward, His Majesty, it appeared, had given orders that as the British Ambassador drove to the station the band should play "God Save the King," so long as His Excellency remained in sight. Sir Frank Lascelles, not knowing the order, however, and hearing the band play our National Anthem, ordered the coachman to stop and rose in honour of his sovereign. The result was humorous. The Ambassador remained standing as long as the band played, and the band played as long as the Ambassador remained in sight. The British National Anthem was therefore rendered several times over, until the Emperor, realising the situation, laughingly sent orders for the music to stop. It is not often that snap-shottists have such an opportunity, as this appears, according to the daily Press, to have been for securing a picture of a notable personage, and at the same time excellent portraits of him under humorous circumstances.

PHOTOGRAPHY AND DAMP.

APART from manipulative faults there can be no doubt that damp is one of the chief causes of failure—and fading in photographic printing. We all know how much sooner the old silver prints on damp walls faded before those in drier situations; so much so that it was quite the usual formula as a salve for conscience, when a blotched, faded albumen was returned, to say, "You must have kept it in a damp place." Damp having this effect on the old albumen print, there cannot be the slightest doubt that it is equally as active a cause of fading in the case of gelatine P.O.P., or, perhaps in a lesser degree, of bromide paper and the gaslight varieties. If, therefore, it is known that silver prints of any description are to be kept in any place where dampness will have access, or where the air itself is at all humid, special precautions should be taken in the framing, such as pasting in the glass, and putting a sheet of damp-proof paper between print and pack, and again pasting the latter in, that is to say, covering over all with stout paper.

Platinotype and carbon are affected to a lesser degree, though we have seen prints in the former process exhibiting all the appearance of bad fading, but of course they could have been restored. The effect of dampness with these processes is that of mildew and a kind of growth on the surface of the prints difficult to remove.

It is not, however, the effect of damp on the finished prints so much as its effect on the paper before finishing that we want to discuss. At this time of the year this is particularly seasonable, as probably November, December, and January are the most humid of months, not an ordinary dampness, but a kind of nasty, sticky variety, penetrating everywhere, and making any work-room without fire or heating apparatus perfectly objectionable and unfit for the storage of sensitive material. If your printing room happens to be of the above variety, and there are many such, only sensitive paper for the day's work should be kept therein. The frames, pads, and blocks should every now and again be placed round a stove, and very probably, if this operation has not been performed for a week or two, quite a volume of steam will be driven off, for the soft wood of printing frames absorbs quite a lot of moisture from the atmosphere. The negatives, too, should be dried over a stove or gas-ring, more especially if they are not varnished. Varnishing is, however, a necessity just now, if you wish to be free from silver stains. Do not be misled by those who say it is unnecessary, and that varnished negatives are more easily damaged than those untreated. All professionals will know this is not the case. Handling hundreds of negatives, as we do, during the year, we can say that never do we print an order (proofs are different) from an unvarnished negative, and frequently, if proofs are taken from a plate without first carefully drying plate and paper, silver-stains result.

Home-sensitised albumen even in summer goes yellow before the fourth or fifth day, and this time is greatly lessened during the winter months. Gelatine P.O.P., though keeping perfectly in the warm weather and in dry rooms, goes yellow in a few days if kept in a room unwarmed. This yellowness, however, fixes out, but we certainly think it should be guarded against.

Platinotype is known as the printing-out paper most affected by dampness, and the different precautions necessary to keep it in fit condition are well recognised. We are surprised, however, that companies supplying carbon tissue do not give warning against damp, for in our opinion carbon tissue is as easily affected as platinotype, and similar precautions should be taken, especially by those buying ready-sensitised material. With reference to this latter, we may mention that not a week ago we obtained a fresh lot of transparency tissue by post at

nine o'clock, printed two or three hours outside in an exceedingly foggy atmosphere, and developed at two o'clock. Every sheet was wholly or partially insoluble, without a doubt due to the humidity of the air. Therefore, we advise the reader to dry his frames in the morning before printing, and also to thoroughly dry his negatives, for it must not be forgotten that the gelatine film can absorb, and does absorb, if it can easily obtain it, a great quantity of water, and this even if the so-called waterproof varnish is used. We should also say, use india-rubber pads, and dry them before use. In large sizes the india-rubber sheeting becomes expensive. American cloth is a good substitute. It should be placed next the paper, and over it an ordinary felt pad.

The storage box to keep tissue should always be thoroughly dry and supplied with waterproof pads top and bottom. At night always take into a room in which there is, or has recently been, a fire. With reference to the Autotype Tissue storage box, we should recommend that tissue be taken out and put in only in heated room, for if damp air gets in, if only in small quantities at a time, insolubility will probably ensue. It is also recommended to only keep bulk in these boxes, taking out sufficient for the day, first thing.

Another point about carbon is to see that the pieces of blotting-paper put between the adhering tissue and supports after first transfer should be kept dried, or proper contact may not occur. This is mentioned as these papers are frequently used over and over again, and, whereas twenty-four hours are easily sufficient to dry them during the warm months, just now they are frequently thoroughly damp.

Another paper easily affected by dampness is the Collodio Chloride. To make it print as well and as richly as usual, it is better to keep a newly opened tube in a warm room for some time. The collodion surface appears to be more apt to crack and blister just now, whether due to cold or damp we are not aware. Again, with mounting, as was pointed out in a recent article, slow drying gives yellow spots, and this slow drying is of course due to dampness in some shape or form. Doubtless the starch, or whatever mounting is used, ferments.

Another annoying thing we all find just now is the fogging of windows and show-cases. There seems to be no remedy except good ventilation top and bottom of glass, and if the obstruction is due to actual fog this is no use.

COPYING BY GASLIGHT.

WINTER is with us, with its short days, dull days, foggy days—days when little or no photography can be done, and then only under conditions far from the best; days when the distracted professional man dreams about arc-lamps, flash-lamps, and magnesium ribbon, but finds himself next morning still struggling in semi-darkness and gloom.

Sitters are scarce, and printing, except on development papers, next to impossible. Grist can be brought to the mill at this time of the year by specialising in enlargements, which are wanted for presents, and photographic Christmas cards; but this creates a good deal of copying work, and copying cannot be done without light. The uncertainty and variability of daylight at this season renders copying far from a pleasant or profitable task, and studio work probably demands one's presence during the two or three hours of good light with which we are occasionally favoured.

Yet almost every photographer has gas in his work-rooms, and I want to show him how he can apply it to his copying-board in such a manner that he will never again trouble about daylight for this purpose.

Fig. 1 shows a convenient form of copying easel, which admits of a vertical and lateral movement to facilitate the centring

of the object upon the camera screen, thus obviating the use of the rising or cross front on the camera, and the consequent removal of the lens's axis from the centre of the screen, which, unless the lens is a very good one, puts a considerable strain upon its covering powers. But that is the usual form of board, and possesses no novel features. It is to the lighting arrangement I wish to draw the professional's attention. Down each of the side supports of the easel is fixed a length of india-rubber gas-pipe, terminating with an L swing-joint and an 8 or 9 inch horizontal arm with burner elbow on which is fixed an ordinary incandescent gas-burner. The two gas-pipes are joined at the back of the board by a T-piece, and a length of india-rubber tube connects this with the nearest gas-bracket, which should have its burner removed so as to permit a sufficient pressure of gas to pass to fill each mantle.

The only addition to the usual incandescent burners is a couple of screens, as illustrated in Fig. 2, which any turn will make for a few coppers. They are made of bright tin cylindrical or parabolical in form, 7 in. in height by 3 or 3½ in. in diameter, with an opening the whole length, 2½ in. wide. The bottom must be soldered to each, with a hole in the centre 9-16 in. in diameter. Through this aperture the burner stem can be passed, when the upper portion is lifted off, and the bottom of the screen (which also serves as a reflector) will

then rest on the loose metal disc which forms the draught screen of the burner, and is held firm by the three projecting feet of the top part of the burner when that is again placed in position.

The burners can be placed at right angles to the copying-board or swing further out as desired. The screens can be turned so that the light is reflected directly upon the photograph or object to be copied, when the lens is screened from direct rays. I need hardly say that the tubes should be fixed so as to bring the mantle in a line with the centre of the copying-easel and level with the lens.

The exposure required with two incandescent burners used in this manner is very brief, and, once ascertained, it only varies slightly with the nature of the object to be copied. The light coming equally from both sides, produces no shadows, and prevents the reproduction of any unevenness or roughness of the print's surface. I am sure that any one who tries this system of lighting his copying-board will hereafter employ it winter and summer alike. By its aid copying can be done day or night, and I have also found it most useful for photographing small articles, such as natural-history or geological specimens. Light and shade can be secured to a nicety by adjusting the distance of the burners from the object—swinging one further away than the other, and thus, by increasing the distance, reducing

the intensity of the light on that side by comparison with the other; and, at whatever angle the bracket is placed, the light can always be directed upon the object and away from the lens by a slight turn of the cylindrical screen.

Another point which I would recommend to all photographers who have much copying to do, is to suspend the whole apparatus from the ceiling at a convenient working height. Then, if the camera, board, or easel receives a knock during exposure, the whole thing swings together, the image is not "moved," and the mantles are not broken. This is particularly serviceable in a building subject to vibration from passing traffic or machinery. If slung over pulleys the apparatus can be drawn to the ceiling out of the way when not in use.

C. C. VEVERS.

PHOTOGRAPHY AS A FINE ART.

ANOPROS the recent exhibitions of the Royal Photographic Society and the Photographic Salon, the "Burlington Magazine" for October remarked that they showed how vast are the advances which photography has made during the last few years. "One illustrates chiefly the convenience and capacity of the process for rendering natural facts in monochrome; the others prove that this literal rendering can be modified in innumerable ways by the operator's dexterity and taste, and the talent displayed may well make one ask if such results do not in some degree challenge the achievements of the older graphic arts. Certain limitations will be obvious to eyes accustomed to look at good painting. The shadows, for example, are heavy and murky, a defect which is especially noticeable in landscape foregrounds. It is for this reason that snow-scenes seem to make better pictures than any other class of subject. Again, a general monotony of surface texture damages the effect of even the most brilliant examples by neutralising much their vitality, and the general aspect of a collection of them is just a little depressing. Local colour, too, seems to tell far more strongly than light and shade, so that the prints are rarely luminous. Natural obstacles, also, will interfere with designs that are otherwise good; awkward forms in landscape foregrounds, for instance, cannot be manipulated with the freedom which a painter enjoys. In the case of portraits, where the lighting and the masses can be deliberately arranged, this disadvantage is far less apparent, and the results in consequence are of a far higher general average. Even the most perfectly arranged photographs thus lack the quality, vibrancy, luminosity, and vitality of fine painting, as well as its marvellous opportunities for creative design (i.e., perfect freedom to select and to emphasise), for colour, and for human skill and sensitiveness in the workmanship; and it is difficult to see how these defects can ever be completely mended. On the other hand, for every painter who succeeds in utilising a tithe of the possibilities of his art, there are at least a thousand who do not, and our art schools are increasing this number at an enormous rate. These unfortunates can neither design, draw, nor colour well enough to produce a work of art, yet year after year they struggle on, hoping against hope, pushing forward products which crowd and embarrass those of better artists, are the despair of honest critics, and a source of confusion to an already confused public. To those who thus possess the artistic temper without the artistic faculty the camera now offers an endless vista of possibilities. It can supply them with powers of delineation such as their hands could never attain; it can free them from the nightmare pursuit of colour harmonies whose laws they can never master. All the enthusiasm and talent they possess is left free for discovering fine subjects and for composing them with taste and personality. Their energies, being restricted only by the resources of a medium which grows more and more flexible every

day, may thus blossom at last into art of a quality to which as painters they could never aspire. Of course, even the finest photography must always remain hopelessly inferior to fine painting in its range, beauty, and suggestiveness. Yet there can no longer be any doubt that good photographs are infinitely more dignified, delicate, and powerful than mediocre pictures. The recognition of this superiority may not become general all at once, for bad painters will be slow to sacrifice the desperate satisfaction of remaining 'real artists'; but come it must, and all good painters will rejoice at its coming."

UNFAIR COMPETITION IN THE PHOTOGRAPHIC INDUSTRY.

[Translated from the "Photographisches Wochenblatt."]

THE company for the manufacture of dry-plates, formerly known as Westendorp and Wehner, of Cologne, which for a number of years has carried on a manufacturing business in photographic dry-plates and other photographic articles at Ilford, London, has registered at the English Patent Office a ticket under the Trades Marks Act. The steamer which this ticket bears was entered as a trade mark at the Imperial German Patent Office on May 15, 1902, under No. 54102, and on October 30, 1902, under No. 56409, with the following note concerning its commercial use by the company: "Manufacture and sale of photographic cameras, dry-plates, and photographic papers. The tickets described are pasted upon grey packing paper used by the company for wrapping the dry-plates made by them, which are intended for export to China."

At the instigation of the American Trading Company, Hamburg, the Ilford Company, Ltd., Ilford, London, also made a ticket, which in size, inscription, and drawing corresponded exactly with the aforesaid ticket of the Westendorp and Wehner Company's, but with the difference that the ticket was not inscribed "The Ilford Empress Plates," but "The Milford Empress Plates," and that instead of the two steamers in circles which are on the tickets of the Westendorp and Wehner Company, two sailing ships in similar circles are used. These tickets of the Ilford Company are also pasted on grey packing paper, which was used for the plates delivered to the American Trading Company, Hamburg, who, as was proved, shipped some of them to China. The Westendorp and Wehner Company thereupon brought an action against the Ilford Company under paragraph 826 of the B.G.B., paragraph 16 of the law for the protection of trade marks, and the law against unfair competition, and sought to restrain the defendants, by penalty for every offence, from offering for sale their dry-plates as Milford Empress Plates, or under any similar description, and especially from use of the tickets complained of; also to forbid the use of such description and packing, and of such descriptions in their advertisements and circulars. The plaintiffs likewise asked for £250 damages.

By decision of the Fourth Court for Commercial Affairs of the General Court of Justice, the defendants were condemned to the payment of £250 damages, and forbidden the use of the description Milford Empress Plates, as well as the plaintiffs' trade mark, upon all their packing, tickets, and other business papers, under penalty of fourteen days' imprisonment for every such offence. By decision of the First Civil Tribunal of the Cologne Upper General Court of Justice, dated October 19 this year, the decision of the General Court of Justice was essentially confirmed, but with the modification that a fine be imposed instead of imprisonment for every offence, also that only the right to damages at present be affirmed, and that the amount be afterwards assessed. The Upper General Court states in its reasons for this decision that the law against unfair competition does not apply to this case, but that the general prescription of paragraph 826 of the B.G.B. does.

According to the correspondence between the defendants and the American Trading Company the defendants wilfully caused injury to the plaintiffs in a way offensive to good custom. It must be particularly described as an unloyal act of the defendants if, to compete unfairly with the plaintiffs, they packed and ticketed their plates in such a manner in order to deceive the buyer in China. This should be judged by the fact whether the defendants' plates were bought as those of the plaintiffs, which had been imported for years. In so doing the defendants had offended against paragraph 14 of the law of May 12, 1894, for the protection of trade marks.

THE LIPPMANN PROCESS SIMPLIFIED.

ONE of the greatest obstacles to the general adoption of the Lippmann process has been the necessity of using the mercury dark slide, and the next the necessity of home preparation of the plates. The former has now been overcome by an announcement made by M. Rothé to the Académie des Sciences of Paris, and proved by several excellent specimens obtained by his method.

M. Rothé argued that it was impossible to remove an extremely thin film of air which must always be present between the gelatine surface and the mercury, and that the stationary waves would be formed by reflection from this film of air alone, and has proved his argument by practical tests, by merely placing a Lippmann plate, glass side to the lens, in an ordinary camera, and obtained good reproductions of the spectrum, a parrot, birds, and flowers.

Hermann Krone in 1891 stated that the mercury mirror was unnecessary, and merely placed a piece of black velvet in contact with the film, but he ascribed the formation of the stationary waves to a "Zickzackspiegelung" in the glass, and was led to this conclusion by his work in connection with halation.

With regard to the exposures given by M. Rothé, they were, as usual in this process, very long—for instance, thirty minutes for an object in the sun, two hours for the same object in a room, and twelve minutes for the spectrum of the arc-lamp. The developer used was weak ferrous oxalate, and the image was bleached with bichloride of mercury, and again blackened with ferrous oxalate.

One of the failures of this process is the want of a good red sensitiser; so far, Neuhauss's mixture of cyanine and glycin red, or possibly Lippmann's methyl violet, would seem to be the most satisfactory, but an experimenter is wanted who will try the new isocyanines in this interesting branch of photography.

AMATEUR Photography—A Celluloid Danger. — D. O. writes to "The Times":—"By way of 'glazing' their photographs amateur photographers frequently press the damp pictures, half-a-dozen at a time, face downwards on a specially-prepared metal sheet about the size of a school slate. To hasten the tedious process of drying the sheet is often put near the fire. A day or two ago I found my wife, bending over the fender with a batch of South African photographs on a patent glazer which she imagined to be talc. She remarked that it was supposed to 'do' them quickly, but that, though otherwise good, it was a slow drier. As the supposed talc looked to me suspiciously like celluloid, I begged her to keep it away from the fire until I should have communicated with the manufacturers. I now enclose their reply. You will see that they state that 'the glaze is made of celluloid, and would be dangerous near the fire.' As knowledge of the fact may save some one a ghastly accident, I think it right to call attention to it. But what shall be thought of people who, with a full knowledge of its highly dangerous qualities, supply such an article for the use of ladies and children without one word of warning?"

SIR JOSEPH WILSON SWAN.

AMONGST the honours bestowed on the King's birthday, we are pleased to see that the dignity of knighthood has been conferred on Sir Joseph Wilson Swan. We, and we know that our readers do, most heartily congratulate Sir Joseph on the well-deserved honour conferred upon him. The "Standard," in its biographical notes on new knights, says:—"Sir Joseph Wilson Swan's name will be handed down to posterity as the inventor of the incandescent electric lamp, and of the dry plate so much used in photography." Here is an error on the part of the "Standard" which it will be as well to correct at once. Sir Joseph is not the inventor of gelatine dry plates, and we are sure that he would be the last to make that claim. The well-known firm of Mawson and Swan were amongst the first to manufacture gelatine dry plates on a commercial scale, but they were not the inventors of them. In connection with photography Sir Joseph's name will go down to posterity as the inventor of the carbon process, as at present worked. It is now forty years ago that Swan patented and published the carbon process (patent No. 503, dated February 29, 1864). A year later (July 6, 1865, No. 179) he patented a method of producing printing-surfaces by photographic agency, termed "Photo-mezzotint Printing." This process was somewhat analogous to the process of Woodbury, and there was some

considerable controversy at the time in the journals as to the two processes. A little later on (1866) Swan took out another patent for preparing paper with an insoluble coating of gelatine by the addition of chrome alum to the gelatine—such as is used for transfer papers in the carbon process. In 1879, Swan took out a patent (No. 2968, July 22) for gelatino-bromide paper, and, at the same time, one for the production of photo-relief plates and producing stipple effects for photo-typography, photo-lithography, and photo-engraving. This process was a few years afterwards re-invented, repatented, exploited, and a company formed to work it; with the commercial success of this the shareholders are well aware. During the same year he patented a plate-coating machine. In 1890, Swan, in conjunction with another, made application for a patent for sensitised films, but the patent was not completed. Sir Joseph Wilson Swan has filled the presidential chair of the Chemical Society as well as that of the Institute of Mechanical Engineers.

PHOTOGRAPHS of Criminals.—A return made from the Habitués Criminals Office states that in the fourteen months ending the 31st of December, 1872, there were 373 instances of detection of prisoners, a having been previously convicted, by identification of the photographs registered in the office. The returns show that 43,654 photographs of convicted criminals had been sent to the Habitués Criminals Office since the Act of 1870 came into force.—From the volume of the "Leisure Hour" for 1873.

SCIENCE v. ART.

The scientific photographer holds much the same relationship to the pictorial worker as does the writer on science to the novelist. Where the scientific man has one patient disciple, the pictorial worker or the novelist has a thousand followers. But the pictorial photographer must look to it that he does not hold the scientific worker at too low an estimate, for the time may soon come when he will be only too glad to be beholden to him. We seem, at last, to be within reach of photographs in colour, and Sir William Abney showed at the Camera Club, the other night, that success in this very difficult phase of photography is entirely dependent upon strict rule and scientific accuracy. The examples of trichrome landscape work, which he projected upon the screen, were certainly the finest things of their kind which have ever been shown. It has been the common cry, hitherto, that the three-colour method, while all very well for flowers and still life, will not produce a good landscape. Sir William has shown that by using plates and screens in harmony with one another, and by careful attention to exposure, most beautiful results can be secured, and landscapes produced which have all the delicacy of carefully-executed water-colour drawings. But, as he said, there is a far greater wealth of detail in the photographs, and here came his opportunity for a slap at the impressionists. Detail, he said, is not now regarded as an advantage, but as a thing to be abhorred. The man who wants his picture hung at the Salon, or at the Royal Photographic Society's exhibition must be a "fuzzyist," or he had no chance of recognition. For his part, he considered that he was too old to think of changing his methods, and he meant to stick to sharp pictures in three colours. There was a time when he considered himself to be a decent photographer, but now he was a pariah, and he thought it best to fall back upon science. We were glad that Sir William thought it well to speak thus strongly of the present fashion in photography, for he certainly is our leading authority. It is very unlikely that the impressionists will take his words to heart, for they will argue that he is not an artist, although they may admit that he is a master of the science of photography. But the pictures exhibited the other night showed that Sir William must possess artistic powers to no small degree. The subjects were most admirably selected, the point of view in every case being that which an artist would choose. Moreover, we learnt from his own lips that he had practised water-colour painting for years, and that now it was a common habit with him to make a colour sketch of the same view which he photographed, so that he might check the one by the other. We fervently trust that some of the fuzzyists will take up this three-colour work, and we shall be curious to see if any one of them will be able to produce by this method more artistic pictures than those exhibited by Sir William Abney.

PHOTOGRAPHY and Astronomical Research.—Professor T. H. Core, who has retired recently from the presidency of the Manchester Astronomical Society, lectured to the members at the Municipal School of Technology last week upon photography in astronomy and some of the important results which had followed from its application to that science. He described the progress which had been made in the use of photography for astronomical investigation since Dr. Herschel, of New York, obtained the first lunar photographs in 1840, and dispelled the idea that it was impossible to photograph the moon so as to produce any effect on a sensitive silver surface. Ten years later Professor Bond, of Cambridge, United States, succeeded in obtaining daguerreotypes of the moon, some of which were shown in the Great Exhibition of 1851. Within the last twenty years photography of the celestial bodies had made rapid progress, principally by adopting more and more sensitive plates. In a series of very beautiful photographs Professor Core showed the appearance of the moon in its first quarter, at the full, and in the last quarter, and also reproductions of areas of star-lit sky. In one of the areas thus covered by the telescope there could be counted, he said, 30,000 stars of varying magnitude. Solar photography, he explained, was first attempted in 1845. In 1857, by direction of the Royal Society, an instrument was prepared for purposes of solar photography by means of which the first sun photographs of any value were taken. The work of photographing the sun was now carried on in every quarter of the globe, and accurate knowledge about the sun and its surroundings had been gathered.

Exhibition.

HACKNEY PHOTOGRAPHIC SOCIETY.

THE following were the judge's awards in this exhibition, which was held last week:—

Members' Classes.—Best Picture in Classes A. to D.: Silver medal (No. 166), W. A. I. Hensler.

Class A.—Portraiture and Figure Studies: Medal (No. 5), Walter Selfe; medal (No. 37), W. Rawlings; certificate (No. 16), W. A. I. Hensler; certificate (No. 50), S. H. Hill.

Class B.—Landscape, Seascapes, and River Subjects: Medal (No. 155), J. Linley; medal (No. 158), F. E. Roope; medal (No. 198), W. Rawlings; medal (No. 222), S. C. Stean; certificate (No. 57), Walter Selfe; certificate (No. 87), J. J. Westcott.

Class C.—Architecture: Medal (No. 224), G. Cathal; medal (No. 251), F. E. Roope; certificate (No. 233), A. W. Cook.

Class D.—Animals, Still Life, etc.: Certificate (No. 287), P. J. Hanson; certificate (No. 292), A. C. Smith.

Class E.—Lantern Slides: Medal, W. A. I. Hensler; medal, F. W. Burt; certificate, F. E. Roope.

Open Classes.—Best Picture in Classes F to I: Silver medal (No. 335), John Hepburn.

Class F.—Portraiture and Figure Studies: Medal (No. 333), Miss M. Silverston.

Class G.—Landscape, etc.: Medal (No. 407), T. Wright; medal (No. 449), B. C. Wickison.

Class H.—Architecture: Medal (No. 463), W. H. Mayne; medal (No. 474), A. W. Walburn.

Class I.—Animals, etc.: Medal (Nos. 478 to 481), W. Morley Martin; medal (No. 493), E. Seymour; medal (Nos. 514 to 526), A. E. Smith.

Class J.—Stereoscopic: Medal, H. Wormleighton; medal, Ernest Law.

Class K.—Lantern Slides: Medal, H. Wormleighton; medal, F. Parkinson; certificate, Graystone Bird; certificates, John Stabb.

Trade Section.—Best display (silver medal), Houghton's, Ltd.; most useful photographic novelty (bronze medal), J. Ashford, for Adjustable Tripod Head.

FORTHCOMING EXHIBITIONS.

November 2-23.—Plymouth. Hon. Sec. Photographic Section, Chas. R. Rowe, 2, Walnut Villas, Cockington, Torquay.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 22-23.—Ipswich Camera Club. Hon. Secretary, R. H. Sutton, 37, Henley Road, Ipswich.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 5.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarnock Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 23-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 133, Glasgow Road, Wishaw.

January 12-14, 1905.—Boston Camera Club. Hon. Sec., H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic

Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 20-25, 1905.—The Cripple Gate Photographic Society. Hon. Sec. John B. Parnham.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Commercial & Legal Intelligence

TAMESIS, LIMITED.—The above-named company has been registered with a capital of £4,000 in £1 shares. Object, to acquire the business carried on at 3, Denman Street, W., as the Tamesis Syndicate, and to carry on the business of photographers, lithographers, engravers, printers, publishers, stationers, designers, advertising agents, and contractors, theatrical librarians, club proprietors, etc. No initial public issue. The first directors (to number not less than three nor more than seven) are H. J. Macfarlane, A. B. Dalton, and J. H. Jennings. Qualification, 100 shares. Remuneration as fixed by the company.

SQUABBLE Over a Portrait.—Before his Honor Judge Allen, at the County Court last week, George A. Poole, an artist, living in Welbeck Street, Nottingham, brought an action against Elijah Goddard, King Street, to recover £5, being the balance of £15 for a portrait of defendant's wife. Mr. Jackson appeared for Mr. Poole, and Mr. Hazeldine represented the defendant. Defendant put in a counter-claim for £10 paid on account. Mr. Jackson said that on the completion of the picture Mr. Goddard was satisfied with it, and sent £10 on account. Afterwards, however, defendant found that his friends did not like it, but, of course, an artist could not undertake to please the artistic tastes of the defendant's friends. Defendant complained of the portrait being coarse. He stated that he sent the £10 because he had heard that Poole was "hard up." The Judge, however, pointed to the letter in which defendant wrote, "I am pleased with the painting." Judgment was given for the plaintiff.

RE RICHARD CROMPTON CLIFFORD, lately carrying on business as a photographer in Wilson Street, Middlesbrough.—The above-named debtor appeared for his public examination at the Middlesbrough Bankruptcy Court on October 19, before the Registrar. The statement of affairs filed by the debtor disclosed liabilities amounting to £768 ls. 7d., and assets, £12 10s.; cash deposited with his solicitor, £10 17s. 6d., book debts (there are bad book debts to the value of £136 6s. 9d.), making, with a reduction of £10 17s. 6d. for preferential creditors, £12 10s. assets, and leaving a deficiency of £714 14s. 1d. The causes of failure alleged by the debtor are "bad trade, bad weather, and sickness." Clifford, who is forty-three years of age, is described as lately residing at 90, High Street, Redcar, and carrying on business at that address, and at 18, Wilson Street, Middlesbrough, and now residing at Crescent Road, Middlesbrough. The Official Receiver (Mr. J. R. Stubbs), in his observations, remarks that debtor commenced business in Middlesbrough in February, 1896, with a capital of £70, borrowed and since repaid. From about March, 1902, to March, 1904, he resided at Redcar, and was the holder of an off-beer licence there, on which he estimated he had lost about £400. Three of the unsecured liabilities, amounting to £430, are for borrowed money. In 1891 the bankrupt filed a petition in the Bradford Bankruptcy Court, with unsecured liabilities of £961 10s. and assets which realised £161 11s. A dividend of 1s. 8½d. was paid; and bankrupt obtained his discharge, suspended for three years, in June, 1892. Bankrupt states that all his assets are included in an ante-nuptial settlement, and the Official Receiver is investigating the validity of that statement. The Official Receiver concludes his observations by expressing his regret that he could not give the information to the creditors earlier, as bankrupt did not file his statement of affairs until Tuesday last. The examination was adjourned for a fortnight.

New Materials.

Christmas and New Year Greeting Cards. Sold by Houghtons, Ltd., 88 and 89, High Holborn, London, W.C.

Messrs. Houghton, Ltd., send us a copy of their special list of Christmas and New Year greeting cards, as well as specimens of cards themselves. Messrs. Houghton have always made a special feature of these mounts, and the enormous trade they do in them is sufficient evidence that the mounts are of real value and that prices are as low as they possibly can be. Particular attention is drawn to some of the most popular series. A red parchment fold slip mount has a very dainty appearance, and is at the same time very striking; the fan design folding slip mount, blocked and bossed on a delicate blue board; the circular-opening white parchment

ment folding slip mount, with a decorative design in green and gold, attached to a white ivory inset, with a dark green ribbon; the Whatman series, and the more simple, but equally popular, slip mounts for either paste-down or slip-in photographs. The series of photo calendars for 1905 are worthy of notice, and so are the "Holborn" Christmas slip mounts with struts, of both of which samples have been submitted to us. The list before us extends to twenty-four pages, so that a vast choice is available by the photographer; while of the specimen cards above referred to, all we have to say in conclusion is that they are strikingly refined and beautiful and deserve to secure widespread popularity for Messrs. Houghton's cards this year-end.

The "Chic" Mounts and Greeting Cards. Sold by Kodak, Limited, Clerkenwell Road, London, and branches.

The series of Christmas-card mounts issued by Messrs. Kodak includes the following:—

Hand-made Series (Green, Brown, and Grey). **Paste-on:** Thick hand-made mounts, with original deckle edges. Heavily plain marked space for photograph and impressed border. Greeting blocked in gold. **Slip-in:** Folding thick hand-made mounts, with original deckle edges. Motto blocked in gold outside. Inside Whatman paper, with opening for photograph, around which is impressed border. **Flat Series:** Matt-art brown, green, and white mounts, with blind blocked design around space for photograph, an embossed greeting. **Paste-on and slip-in.** **Folding Series:** Thick white hand-made mounts, with original deckle edges, greeting embossed in colour outside, and space for photo, blind-blocked inside. **Paste-on only.** **Calendar 1905 Series:** For slip-in photos. Green and brown matt-art boards, with silk loop and calendar for 1905. **Folding Series:** Thick white Whatman and green, brown, and grey matt-art mounts, with paste-on and slip-in space for photograph the outside. Silk tassel and greeting on cover. Inset with motto and greeting. **Folding Series (Green, Brown, and Grey Matt-Art Mounts):** Embossed design and greeting on cover. Inside of thick Whatman paper, with cut-out opening for photograph and blind blocked border around opening. **Slip-in only.** **The Scarlet Folding Series:** Similar to the above, but in scarlet only, with plain embossed design and white embossed greeting on cover.

Practically every size of photograph up to half-plate is catered for in this delightful series of tasteful mounts—tasteful, that is, in design, tone, and form. They should be enormously popular this season. Messrs. Kodak also issue an album containing samples

"Chic" private greeting cards, with prices quoted so that the retailer or user may make a suitable selection. All photographers should make the acquaintance of the "Chic" series.

The Rotary Photographic Company, of 12, New Union Street, Moorfields, London, E.C., write:—"We have much pleasure in sending you herewith packets of our latest introductions, 1-plate 'Court' postcard and carbon tissues, in 17 colours. The 'Court' postcard has been produced in response to the continual demand of the 1-plate user, who has hitherto had no postcard of a suitable size to use the whole of his negative without considerable masking. The cards are cut with rounded corners, which adds considerably to the artistic appearance of same. As with all our other sensitised cards, we supply the new size both in Rotograph (bromide) and Rotox (gaslight), each matt and glossy, and these cards are listed at popular prices, viz.: 1-plate packet of 12 and three masks, or 5s. per 100, 6s. 9d. per gross. The carbon tissues are supplied in 17 colours, in an artistic range of colours, which offers a more varied selection of tints than the carbon printer is accustomed to." We hope to report on these products from practical trial at an early date.

New Books.

"Photograms of the Year 1904." London: Published by Dawbarn and Ward, Ltd.

"Is photography Art?" "No." "Can it be used to express artistic feeling?" "Yes." "Then let us so use it." This morsel of imaginary dialogue is printed on the first page of the tenth annual issue of "Photograms of the Year." If such a commonsense definition of the position of photography amongst methods of graphic expression had been promulgated half a century ago the world would have been spared the affliction of much verbose nonsense as to the claims of photography to be ranked as a fine art, and that "recognition" for which such gentlemen as Mr. Stieglitz and his friends are belatedly clamouring to-day would have been vouchsafed years ago. For no spectacle on this earth is so pathetic and so painful as that of the photographer trying to persuade the world and his wife that he is something altogether different from what he appears to be. The volume before us contains numerous reproductions of examples emanating from the various photographic "schools" of the day, selected from the R.P.S. and Salon Exhibitions, the Scottish Salon, Australia, British Columbia, France, Germany, and the United States. Thus its representative character cannot be denied. The literary and critical contents are as follows:—"Pictorial Photography in France," by Robert Demachy; "Pictorial Photography in British Columbia," by H. Mortimer Lamb; "Notes from Australia," by A. J. Hill-Griffiths; "A New Departure in American Pictorialism," by Sadakichi Hartmann; "Suggestions to Would-be Picture-Makers," by H. Snowden Ward; "The Two Great [English] Photographic Exhibitions," by A. C. R. Carter; I. The Photographic Salon; II. The Royal; "The Western Workers in the United States," by Fayette J. Clute. We also have an unsigned paper advocating, or at any rate discussing, a possible fusion of the Royal Photographic Society with the Photographic Salon. The feasibility of the idea is, we fear, somewhat remote, although it is one which neither in our journalistic nor our personal capacity would we at all oppose if once it came within the sphere of practicable politics. For there is no longer room for two "great" exhibitions running concurrently each autumn in London. The volume before us is full of valuable and discriminating criticisms of the photographs reproduced, and its perusal and study cannot but be found helpful by the aspirant after success in pictorial photography.

The Velox Manual. Published by John J. Griffin and Sons, Ltd., 20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C. Price 2d.

This little book deals exclusively with velox printing. Manipulation of the paper, exposure and development, fixing, washing, drying and mounting, each receive separate attention, and there is a special section devoted to causes of failure and remedies. Formulæ are also given for colour-toning. The manual has evidently been compiled with great care, and is rendered additionally valuable by the inclusion of articles by Mr. F. M. Sutcliffe, Mrs. Cadby, Mr. John A. Hodges, and Mr. Chapman Jones, one of which we take the

liberty of reproducing. The Velox Manual should be in the hands of all lovers of the charming process with which it deals.

Mrs. Cadby's article is about printing Velox postcards. Appropriately enough, Messrs. Griffin have just introduced two new Velox postcards. These are Art Velox and Portrait Velox. The surface of Art Velox is semi-glossy. These are sold in packets of eighteen, with two masks, for 1s. The Portrait Velox surface is a delicate egg-shell half-matte, and the price of the cards is 1s. for twelve with two masks. Messrs. Griffin also now issue their Carbon Velox postcards at the price of 1s. for eighteen, with two masks, instead of twelve as formerly.

"Retouching." By Arthur Whiting. London: Published by Dawbarn and Ward, Ltd. 91 pp. Illustrated. Price 1s.

This is the second book on retouching that has recently come under our notice. Quoting from the publishers' preface, it is a handbook of retouching negatives by modern methods with pencil and knife. The text deals with working methods and the preparation of tools and materials, and with the procedure in retouching portrait and landscape negatives. Special work, such as removal of halation, retouching draperies, working in clouds, etc., is considered, and there is a collection of formulæ. The supplements include "Examples of Knife Work in remedying Defective Negatives," "The Stages of a Portrait Negative from the Un-retouched to the Over-retouched State," "Forms of Clouds and Skies Drawn in Negative for Working into Landscapes," "Touches to be employed in working up various kinds of trees," and "Examples of halation removal." Mr. Whiting is an experienced professional retoucher, and his book embodies a vast amount of theoretical and practical knowledge of his subject. The anatomical and other illustrations will be found of the greatest service by the practical student of this branch of photographic work.

"PHOTOGRAPHY" BOOKSHELF.

Recent additions to this useful series of handbooks, which is published by Messrs. Iliffe and Sons, Limited, of Tudor Street, E.C., at one shilling per volume, include "Practical Retouching," by Mr. Drinkwater Butt, F.R.P.S.; "Intensification and Reduction," by Mr. H. W. Bennett, F.R.P.S.; and two volumes on "Professional Photography," by Mr. C. H. Hewitt. The latter, in particular, are well worth study by those who intend making a business of professional photography. To quote our author, the volumes have been "written in the hope that they might interest the professional worker and lead him to a further study of matters—the mere fringe of which is here touched. The labour market is flooded to-day with workers—employers, employed, and unemployed—whose knowledge is merely superficial or elementary. It is only by close application to the less ordinary matters that the ambitious may find the vacancies always existing "at the top."

Patent News.

The following applications for Patents were made between October 31 and November 5, 1904:—

Lens Shades.—No. 23,411. "Improvements in photographic lens shades or screens." Charles Henry Fryer.

Cameras.—No. 23,518. "Improvements in photographic cameras." Francisque Pascal.

Washing Racks.—No. 23,581. "Improvements in washing racks for photographic plates." Walter Henry Harrison.

Pigment Paper.—No. 23,766. "Improvements in and relating to photographic pigment paper." Albert Höchheimer.

CINEMATOGRAPHY in Colours.—According to the "Photographische Chronik," Dr. Miethe, of Berlin, has attempted to obtain cinematographic films in colours by the three-colour process, using for this purpose ordinary negative films sensitised with eosine, ethyl red nitrate with a small addition of chinoline red. The lens was worked at an aperture of F. 3 or F. 4, and the filters placed in a rotating sector in front of the film were moved synchronously with the same. The apparatus used for projection was built on the same lines, but the results showed but faint traces of colour, and a "ghastly flicker." Dr. Miethe hopes to obtain better results by using a film three times the ordinary width and placing the filters side by side.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
21.....	Camera Club	<i>The Capabilities of the X Rays.</i> Dr. G. W. Rodman.

ROYAL PHOTOGRAPHIC SOCIETY.

ORDINARY Meeting, November 8.—Major-General J. Waterhouse, I.A., vice-president, in the chair.

Nearly sixty candidates for membership were proposed or elected.

The chairman read a letter from the Royal Commission for St. Louis Exhibition announcing the award of a grand prize to the Society for its collection of scientific photographs.

In the absence of the president, the chairman then presented their medals, won at the New Gallery at the recent exhibition, to Mr. Arthur Marshall, of Nottingham, and Mr. Arthur C. Banfield. Mr. F. J. Mortimer, absent through illness, was represented by Mr. Thomas Bedding, F.R.P.S. The other medals were ordered to be transmitted to their owners, none of whom could be present.

Mr. E. Walter Maunder then gave a lecture on "Recent Astronomical Photography at the Yerkes Observatory." In his opening remarks the lecturer said that the services of photography to astronomy were so great that an astronomer appearing before the Society must do so with a feeling of gratitude. The great telescope at the Yerkes Observatory, which is built on the Lake Geneva, Wisconsin, and presented to the Chicago University, was erected and equipped by Mr. Yerkes. The lecturer, after giving the various measurements of the observatory, said that the object glass of the great telescope weighs, with its cell, nearly half a ton, and is forty inches in diameter. The floor rises and falls through twenty-three feet by means of electrical mechanism, designed by Sir Howard

Grubb, and the movement of the whole—a weight of thirty-seven tons—is effected in a like manner. Slides of the spectra of various stars were shown, as well as a number of the sun's irradiations during a total eclipse. The objective of the telescope being uncorrected photographically, means had to be devised by which it could be used for photography. The difficulty was overcome by the employment of a sheet of glass worked optically plane, coated with lodion stained yellow, and used in front of the photographic plate. Mr. Maunder stated that the use of this isochromatic screen not appreciably prolong the exposure—a rather curious fact, judged from the usual photographic standpoint. A number of lunar photographs were also shown in which portions of the moon's surface resembling terrestrial mountain ranges were depicted. From this it could be determined that, at any rate since their formation, the moon has possessed no appreciable amount of atmosphere since otherwise one would find traces of watercourses, which, however, are entirely absent. With an aperture of fifteen inches the Yerkes telescope will give a photograph of a star of the 17th magnitude with an exposure of two hours.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the general committee was held at 51, Baker Street, on Friday, November 11. The following members were present: Messrs. T. C. Turner (Hull), A. Ellis, F. A. Bridge, A. Mackie, H. Mendelssohn, E. Scamell, S. H. Fry, R. Fellows Willson, H. Spink (Brighton), E. C. J. Elliott, D. Prodder, Lang Sims, H. McInds Hull, A. C. Banfield, Martin Jacollette, P. Lankester, Wm. Grove; Mr. T. C. Turner, president, in the chair.

Mr. William Grove was unanimously elected hon. secretary and treasurer, and Mr. A. Mackie assistant secretary.

It was reported that, notwithstanding the invitation given through the medium of the JOURNAL to all photographers and others interested to criticise the draft prospectus of the assistants' certificates scheme and to suggest amendments, not a single letter had been received except from members and their own assistants. A large number of members have written expressing unqualified approval, and there was also a large number of letters containing suggestions. The reading of these occupied much time, and finally it was agreed to refer them to the sub-committee which had previously acted in the matter for consideration, and to embody those of the suggestions which were practical and sensible in the prospectus. It was further agreed that the amended prospectus should be passed at the next committee meeting. It should then be put into force for the next twelve months; at the expiration of that period the committee would be able to discover its weak points, if any, and to rectify them.

The subject of the formation of a benevolent fund was then discussed. It was decided that before pledging the Association to the course, every member should be given the opportunity of stating whether he approved of the idea, and, in the case of approval, what sum he was prepared to subscribe annually.

CAMERA CLUB.

MONDAY, November 7, was an "open night" at the club, by which it is meant that there was no formal lecture, but members were invited to bring before their colleagues anything of interest; and in this way matters get discussed in a free and easy manner, which is both pleasant and profitable. On Monday the ball was opened by the hon. sec., who handed round for inspection a very old Daguerreotype portrait, the details of which were scarcely distinguishable. He then passed round an enlargement on bromide paper, which had been made from it by professional hands, and every one agreed that the work had been wonderfully well done. The hon. sec. wanted the opinion of those present as to how the work had been accomplished, and said that the original Daguerreotype presented such difficulties. One member suggested that the portrait had been copied in a very strong light, and that an isochromatic plate and screen had been used. Another thought that an ordinary plate had been employed, and that the thin image obtained had been bleached with mercuric chloride backed with black velvet and treated as a positive. That this had been recopied so as to get a strong negative from which the enlargement was made. Other matters were brought in an informal way before the meeting, but they do not call for notice.

The following Thursday found a large audience to meet the president of the club, Sir William Abney, who had promised to discourse upon "Photographs in Colour," and everyone was on the tiptoe of expectation and asking whether there would be any novelty to disclose. The lecturer did not attempt to theorise, but assumed from the outset that most of his hearers had no need of instruction with regard to the general outlines of the trichromatic method of producing pictures. He knew that numbers of people were busy with this very fascinating aspect of photography, and he could only express his regret that many of the pictures turned out were the reverse of satisfactory. He considered this general failure to master the intricacies of the process to be due to neglect of details, to want of accuracy in the choice of colour screens, in the production of suitable negatives, and in exposure, and he proceeded to point out the tests which should be adopted to secure accuracy in all these particulars. But the supreme test of a trichromatic picture was its projection upon the lantern screen with suitable apparatus.

Photographers were too apt to fancy that when once they had furnished themselves with a set of colour screens, those screens would be suitable for any isochromatic plate on the market. This was not the case, each plate requiring its own particular colour filters. Another mistake which was often made, and he had been astonished that any reasonable person could fall into the error, was to test isochromatic plates by gaslight, and he showed by a diagram the different luminosities possessed by gas, by the electric light, and by daylight.

After describing the apparatus which was on the table for projecting the three positive images through coloured screens to coalesce on the screen, Sir William proceeded to exhibit a large number of pictures, all landscape, which he had taken by the trichromatic method, both in this country and abroad; and very beautiful examples they were, showing, as they did, that the delicate colouring of distant hills and snow-clad mountains could be as well reproduced as the flowers, fruit, and studies of still life which have hitherto formed the chief subjects of the trichromatic worker. The pictures proved the soundness of the theory upon which the process was founded, a theory which had been worked out on scientific lines by a most competent experimentalist.

The first person who was called upon by the chairman, General Butterhouse, to express an opinion upon these pictures was very appropriately an artist, Mr. G. A. Storey. He said that he would have much preferred to hear the opinions of others first, for he himself was no photographer. These pictures were a revelation to him. It was like stepping out of night into day. They reminded him of the work of some eminent painters—Turner, for example—especially in the beautiful atmospheric effects. He also noted how the colour had the effect of separating the different planes of the picture; indeed, they were all the source of great delight to him. As pictures they were charmingly selected. He regarded them, not as perfection itself, but as the way to perfection. He hardly liked to say anything of a disparaging nature concerning them, but he considered that they were perhaps wanting in that immense variety of colouring which one saw in nature. Taken as a whole, they were most beautiful pictures.

After a few remarks by Mr. Cadett, Mr. Sanger Shepherd, and others, the lecturer replied to the criticisms which had been advanced. He said that artists always improved on nature, and that he had seen paintings with a variety of colours which no mortal man had ever seen in nature. He had always dabbled in art, and was pleased to find how closely his water colour drawings agreed with the trichromatic pictures taken from the same spots. The meeting closed with the usual vote of thanks.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held November 10, Mr. E. Human in the chair.—A series of bromide prints, toned with the Geka chromatic toning preparations, were exhibited; also a set of the Geka light filters for dark-room illumination. Mr. Rapson initiated a discussion upon the use of incandescent gas for copying purposes, having tried various arrangements, but could not get quite satisfactory results. One light required an exposure of two minutes, and three lights were required to reduce the exposure to one minute, and beyond the three any further addition had very little effect upon the exposure, the reason apparently being that increasing the number of lights resulted in volume increase, but not in intensity. Mr. Drage had packed some films after exposure in tinfoil, and the image had apparently faded, as only a ghost of an

image would develop, whilst films packed only in paper, without tinfoil, taken under similar conditions, were quite satisfactory. The subject was discussed at length, but the mystery was left unsolved. Mr. Freshwater was congratulated upon being in the list of winners of awards at the St. Louis Exhibition.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION (LIVERPOOL BRANCH).

A MEETING was held at the Alexandra Hotel, Dale Street, Liverpool, on October 28. There were present G. Watmough Webster (chairman), A. F. Mowll, A. Priestly, T. Vanderbilt, J. Saronie, O. Looser, W. Cowper, S. Hibberd, R. H. Waite, W. Smith, and W. Warrington (hon. secretary).

Arrangements for the meeting on November 4 to discuss prices came forward. The Secretary reported "that he had sent, as arranged, circulars to all professional photographers in the district inviting them to be present. That he had received two letters in consequence, one from a lady, asking if she were eligible to be present, being a professional photographer, to whom an assurance of welcome had been sent; the other from a member of the branch, saying, 'He must decline kind invitation to discussion re prices, etc., as personally he did not think any good would come of it.'"

The Chairman then read a letter which had been received from the hon. secretary in London relative to the present discussion, and said their thanks were due to him for this expression of his views on the point. The clear and common-sense nature of them would certainly help all to see the matter in its general and wider bearings as well as in the particular and narrower application. The letter ran:—

"The fact that we do not feel the evil effects of price-cutting as you seem to do perhaps prevents us from realising your trouble. Many of us are inclined to think that you sometimes apply the term price-cutting erroneously to what is really the natural gravitation of prices when quality falls off. If there are, say, two photographers so situated that they are competitors in business, and one of them turns out distinctly superior work, if these prices are the same that one naturally gets the cream; the other, in order to live, instead of improving his work, as he should, frequently lowers his prices. That, strictly speaking, is not price-cutting; it is merely offering the inferior article at its relative value. I can quite understand, however, in a place like Liverpool, where there are many photographers all doing about the same class trade, that the illustration I have given can hardly be applied, and that an intolerable state of rate warfare may exist. If all photographers were honourable and common-sense men of business there would be no difficulty in coming to a satisfactory arrangement at such a meeting as you propose. Photographs, like other commodities, have their value paid by supply and demand; but, unlike some other commodities—tea, for instance, the price of which is fixed by the supply at the gardens and the demand of the whole world—it is the supply and demand of the locality which fixes the price of photographs, and the supply is entirely controlled by the photographers themselves. If they decide not to charge less than a certain minimum price it would not affect the demand, for people do not get photographed because photographs are cheap, but because they want the photographs, and they are quite willing to pay a reasonable price for them. I am referring to the standard sizes—cabinets, etc.—and not to the 6d. and 1s. a dozen things.

"With regard to your remark that some photographers stay outside the Association because there are unduly cheap men among the members, that seems to me to be an extremely narrow-minded view. We have some chance of negotiating with our own members, but outsiders can defy us completely. The parson never complains of the wicked coming to church; he complains he cannot get at them because they stay away."

Further general discussion of the subject followed, and of some of the difficulties in the path of the Association's work, such as the attitude of some photographers, who would not join because among the members were some to whose prices they (the outsiders) took exception. In inviting membership this point had arisen again and again. The hon. secretary of the Association, all agreed, had described such correctly as taking a very narrow-minded view, because, when necessary, it is possible to negotiate with members, while outsiders are practically out of reach. Some photographers, it was allowed, would expect the P.P.A. to solve all questions of competition for them, whereas it must be evident to reasonable minds that com-

petition must always exist, and that efforts such as the present were in the direction of keeping such competition along reasonable and fair lines. The members present represented widely different scales of prices, but it was unanimously hoped that the fact would never be a source of discord among them.

CROYDON CAMERA CLUB

NOVEMBER 9.—Enlarged negatives on glass and paper, respectively dealt with by Messrs. F. W. Hicks and W. H. Rogers, formed an interesting and, to the less advanced members, a most instructive topic. According to Mr. Hicks, who, so to speak, opened the batting with glass plates, if one had a suitable transparency to start with, the subsequent production of an enlarged negative was a matter of comparative ease, provided a good slow plate, such as Wratten's Ordinary, was employed. With a slow plate there was a very wide latitude in exposure, and a comparatively bright light could be used when developing, which was a comfort. A test exposure should, of course, be made on a quarter-plate, of preferably the same batch, and with ordinary care the enlarged negative should certainly never turn out to be a waster. Personally, he did not favour paper negatives, leaving out of the question the slowness of printing, and grain, due to the support, if one wished to retain any length of scale, or delicate gradations, then a dry plate, in his opinion, was absolutely necessary. Mr. Hicks brought his remarks to a conclusion by exposing and developing two really excellent 15 x 12 enlarged negatives, pyro being the developer employed.

Mr. W. H. Rogers, who had evidently been listening "more in sorrow than in anger" to Mr. Hicks's expressions of opinion respecting paper negatives, energetically defended them. They were far and away cheaper, unbreakable, stored easily, and last, but by no means least, any amount of handwork could be applied to the back. The grain, moreover, need not be obtrusive, at all events in large work, and printing was not so slow as was frequently made out. He resented an observation Mr. Hicks had made earlier in the evening that their best use would be to form a wall-paper. If this were true, then Mr. Hicks might, with equal advantage, utilise his glass negatives towards the construction of a greenhouse. Having in his turn filled the office of special pleader, Mr. Rogers proceeded to expose and develop some bromide paper negatives, which, from the paper negative standpoint, left nothing to be desired. For this class of work he preferred edinol as a developer.

RICHMOND CAMERA CLUB.

NOVEMBER 11.—A lecture was delivered by a representative of Messrs. Sanger Shepherd and Co. on the three-colour process. After showing a few lantern slides in natural colours, the lecturer threw upon the screen an illustration showing the divisions of the spectrum and a photo showing the effects of the light waves upon an ordinary photographic plate, which, as he explained, is not equally susceptible to the different wave lengths of light, for whilst the yellow waves are the most conspicuous to the eye the violet are the most active on the plate, and the red rays have scarcely any effect upon it. Another illustration showed the effect produced by the use of an orthochromatic plate with a light filter specially adapted for the particular emulsion employed, the light waves by this means acting almost uniformly throughout the length of the spectrum. He then showed and explained the results obtained by the division of light into thirds of white light and by superposing the thirds upon one another, thus reproducing white light. Another slide showed negatives of white, red, yellow, green, blue, and black squares, when photographed under red, yellow, and blue screens, and positives printed from these negatives which, when superposed upon one another, resulted in the reproduction of the original colours. The lecturer then showed and explained the Sanger Shepherd apparatus, and gave lucid details of the application of the process to the production of lantern slides and prints in natural colours. He also showed lantern slides taken upon an orthochromatic plate which gave the usual effects of monotone, and the same subjects taken under a colour screen suited to the plates employed, to show the correct rendering of the light. He explained that the most satisfactory results are obtained by the use of a screen which lengthens the exposure ten times, and it becomes a case of deciding whether it is better to have correct rendering of the light, accompanied, possibly, by some movement of trees, or to be satisfied with the ordinary dull monotone picture. Afterwards a

number of slides in natural colours were shown, among which were some very fine landscapes and Swiss scenes by Sir William Abner. Other slides were shown to illustrate faults in working, which were pointed out and explained.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.

The second meeting of the session was held in the club rooms, Museum, College Square North, last week. Mr. D. Elliott presided. The hon. secretary (Mr. Thomas N. Murray) read a letter from Mr. Sims regretting that he was unable to attend and give his demonstration on the working of bromide papers for contact and enlarging work, etc. By the courtesy of Mr. J. Lizars, who lent a very excellent series of slides of the Russo-Japanese War, followed by a very fine cinematograph show of new films, the members were enabled to enjoy a pleasant evening. Amongst the slides shown were: The Russian fleet in Port Arthur, Cossacks in Manchuria, a military train crossing Lake Baikal, Emperor of Japan, Vice-Admiral Togo, Baron Kuroki, Baron Oku, General Stoessel in command of Port Arthur, etc., so sixty in number. The lantern, etc., was carefully worked by Mr. Buik, of Mr. Lizars.

CROYDON SCIENTIFIC SOCIETY.

ON Friday evening last the members of the photographic section of this Society were treated to a masterly exposition of some of the chief products of Messrs. R. and J. Beck, by Mr. W. F. Slater, of photographic tourist fame. Lenses claimed the first consideration because Messrs. Beck make quite a speciality of these, and none is more remarkable than their Unofocal Lens, which has an aperture of $f/4.5$, and it can be used at this aperture either alone or in combination with a negative attachment, as a tele-photo lens; rapidity and optical excellence is such, that at this large aperture a tele-photo picture may be obtained in a bright light at even 1.40th or 1.50th of a second.

The principles involved in the making of lenses, and the corrections for aberration and astigmatism were explained and illustrated by lantern slides, as also was the use of stops and the way in which these acted.

Cameras next claimed attention, and of these, two specialities merited attention, *i.e.*, the Dal-Cornex and the Telephoto-Cornex, the first being a magazine camera of box pattern, having a simple and reliable changing system, while the second was a modification of this, enabling it to be used as a tele-photo box camera. The way in which the necessary extension was obtained, and the quite novel way of adapting the negative lens, was as simple as it was original—a small rod pulled the attachment into position after the camera had been extended, and pushed it out of the way again before the camera was again closed; thus, without opening the camera or adding anything to it or taking anything away, an ordinary hand camera or a telephoto camera could be obtained in the shortest possible time.

Finally two very ingenious arrangements were shown for changing plates or films which struck us as even more simple than the film packs, and they could moreover be used over and over again as nothing had to be torn off and thrown away. Mr. Slater was heartily thanked for his lucid explanations.

The photographic enlargements exhibited by the Grand Junction Canal Company at St. Louis Exhibition were made, we are informed by Mr. Frank Wakefield, of 137, High Street, Brentford.

THE Optical Society.—The student's meeting in connection with the society have started for the session 1904-1905, and the attention of those under the age of 25, who are interested in optics, either from a scientific or business point of view, is directed to the advantages offered by the society to those joining the student section. The advantages take the form of half subscription, together with the privilege of attending all ordinary meetings of the society. Meetings for students are arranged which are distinct from the ordinary meetings, at which short papers are read and discussed, and are held usually on Thursday evenings at the headquarters of the society, 20, Hanover Square, W. Further particulars and forms of application for membership can be obtained from the Hon. Sec., Mr. W. Salt, 20, Hanover Square, W., or from Mr. H. C. Patey, 70, Blenheim Gardens, Willesden Green, N.W.

News and Notes.

MESSRS. J. EPSTEIN AND Co., of 33, Broad Street, Bristol, inform us that their new price list is now ready.

At St. Jude's Institute, Mildmay Park, London, N., on Friday, the 11th instant, Mr W. J. Sadler gave a successful lecture on photography, illustrated with practical demonstrations.

THE Nepera Division of the Eastman Kodak Company, Rochester, N.Y., kindly send us a post-card souvenir of their Kodak Park Plant, Rochester, N.Y., U.S.A.

MR. J. LIZARS, of 71, Bold Street, Liverpool, announces free demonstration classes every Friday evening in enlarging, bromide, and easel papers, making lantern slides.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the present month has been awarded to Mr. J. Dunlop, Myrtle Bank, Motherwell, N.B., for his negative "A Woodland Scene."

THE Lost Goerz Lens.—Mr. C. P. Goerz writes:—"Referring to my letter of the 5th inst., I am sorry to find that I did not mention the number of the Double Anastigmat Series 1 B. therein referred to. I should be glad if you would mention that its number is 132,020."

THE Right Hon. Lord Reay, G.C.S.I., G.C.I.E., LL.D., etc., will deliver the prizes at the Northampton Institute for the Session 1903-4 on Friday, December 9, at eight o'clock. The prize delivery will be followed by a conversazione, which will be continued on Saturday, December 10.

THE St. Louis Exhibition.—Messrs. Newton and Co., of 3, Fleet Street, London, E.C., have been awarded three gold medals and one bronze for their optical lanterns and slides, and coils for wireless telegraphy. Mr. T. E. Freshwater has been awarded a silver medal for his photomicrographs of rock sections.

At a meeting of the Hillsborough and District Photographic Society, held on Wednesday, November 9, Mr. T. G. Hibbert gave a very interesting demonstration on "Lantern Slide Making." A large number of his own slides were exhibited, as also were the "Camera Notes" prize lantern slides. Altogether it was a very enjoyable evening.

MR. C. P. SALTMARSH, of 44, Market Square, Witney, Oxon, writes:—"I beg to inform you that I have opened a photographic studio at the above address for the production of high-class work in all processes. Mr. S. P. White (formerly with Messrs. J. Russell and Sons, Court Photographers, of London and Windsor), will have charge of the business."

A POPULAR edition of "Astronomy for General Readers," by Mr. W. F. Chambers, F.R.A.S., has been issued by Messrs. Whittaker and Co., of 2, White Hart Street, Paternoster Square. The work, which has 134 illustrations, is published at the price of one shilling, and is written with such simplicity of style that it cannot fail to be easily understood by the class to which it is particularly addressed.

THE death took place recently of Mr. J. H. Blackburn, photographer, of Swan Croft, Colne. Mr. Blackburn was well known in the town, owing to the fact that he reproduced many old views of the district. For many years he had been the principal in his line of work, and prior to moving into his present premises occupied a shop in Stanley Street. He leaves a widow and family.

MR. T. WHITE, the new Mayor of Lewisham, is a photographer carrying on business in the High Street, Lewisham. He is an active Radical politician, being the Liberal party agent for registration and other work. It is undoubtedly due to his efforts, in the face of great odds, that the Lewisham Borough Council has now a Progressive majority.

SILICATEPHISCOGNOSCOPHOGRAPHY. — According to the German trade paper, "Die Photographische Industrie," a society has been formed in New York which has for its purpose a study of the properties, and the application, of silicate compounds for photographic purposes. A journal is to be run under the title of "The Silicate-phiscognoscophographer." We understand that the actual idea of the society is to study glasses, but whether full or empty is not said.

"TONING Bromides and Lantern Slides," by Mr. C. Winthrop Somerville, F.R.P.S., published by Messrs. Dawbarn and Ward, Faringdon Avenue, E.C., price 1s., summarises the various chemical methods available for the colour-toning of bromide prints. The author is known to be a master of his subject in theory and prac-

tice, and as his instructions are well reasoned and tersely conveyed, the book may be accepted at a reliable guide to a very fascinating branch of printing.

A BRIGHTON Photographic Exhibition.—The prize-winners in the photographic exhibition, organised by Hardcastle's, Limited, of East Street, Brighton, are Miss M. A. E. Tozer, Hove (a figure study), Mr. T. L. Lambert, Brighton (the reredos, Lichfield Cathedral), and Mr. J. Brooks, Brighton (farm horses). Many prints of great merit were sent in, and the photographs can still be seen at Hardcastle's. The judges were Messrs. E. J. Bedford (Eastbourne) and A. H. Corder (Hove).

THE Altrincham Photographic Society held its annual general meeting on Thursday evening, November 3, 1904. The election of officers for the Session 1904-5 resulted as follows:—President, Rev. L. W. Thomas; Vice-presidents, F. Kenyon and W. H. Short; Committee, T. Rowlands, J. Tonge, J. Harris, junior, E. T. Whitelaw, W. M. Blackshaw; Hon. Sec., D. Stanley Morrison, Ashley Road, Altrincham; Portfolio Secretary, T. R. Foxcraft; Treasurer, C. Rutter; Auditor, A. H. Burgess.

SOUTH LONDON Photographic Society.—An interesting and valuable lantern lecture was given at a recent meeting by Mr. A. Bedding, entitled "A Ramble Round the Tower of London." The lecture was the result of some years of work, and among the slides were views of many historical chambers and prison cells never shown to the public, and for which the personal permission of the Constable of the Tower had to be obtained. The Regalia, being in a glass case, is very difficult to photograph, yet the resulting slides were probably the best of the evening.

THE following is a list of the prize-winners in the October Ensign Film Competitions:—First prize, £10, J. H. Brookes, 32, Waldegrave Road, Upper Norwood, S.E.; second prize, £5, Miss Makechnie, 26, Commercial Road, Eastbourne; third prize, £1, W. E. Coxhead, 36, Monson Road, New Cross, London, S.E.; fourth prize, £1, E. H. Kellam, 35, The Arcade, Great Yarmouth; fifth prize, £1, Mrs. G. Green, 77, Womington Gardens, Reading; sixth prize, £1, Miss E. M. Kendall, Greenhays, Kingswear, S. Devon; seventh prize, £1, A. J. Freeman, 2, Park Villas, London Road, Newbury, Berks.

THE Christmas number of "Photography," published by Messrs. Iliffe and Sons, Limited, of 20, Tudor Street, London, E.C., is, as usual, an elegant production. Its main theme is winter camera work. Part I. consists of an exhaustive article on "The Working Up of Negatives and Prints," by Mr. C. J. Harrison; and Part II. "Bye-Paths of Photography," by Mr. W. F. L. Westall. Both articles are fully illustrated, and they are full of sound, practical information by able photographers. This Christmas number, unlike most so-called seasonable literature, should be found useful all through the winter.

PHOTOGRAPHIC CLUB.—The annual general meeting was held on the 3rd inst.; Mr. F. A. Bridge in the chair. The officers elected for the ensuing year are as follows:—Trustees: Mr. F. A. Bridge and Mr. H. Snowden Ward, F.R.P.S. Committee: Messrs. R. R. Beard, A. L. Bell, D. Bradford, G. Edey, J. R. Gotz, F.R.P.S., A. Mackie, H. Müller, H. P. Smith. Hon. Secretary and Treasurer: T. W. Derrington. Several alterations were made in the rules, the most important being the reduction of the annual subscription to five shillings. An inaugural supper will be held on November 23 at the club's new quarters, Red Cross Hotel, 19, Paternoster Square, E.C., at 8 p.m.

IN Sicily with a Camera.—Miss Ethel Heywood lectured before the Manchester Geographical Society last week on Sicily. Her lecture was an account of a tour "as an experimental geographer" undertaken in 1899, and it was illustrated by photographs of Sicily's archaeological and architectural riches. Miss Heywood said that a woman when travelling must decide whether to enjoy herself or take photographs. She took many photographs—and some excellent pictures were thrown on the screen—but her audience, having listened to the lecture, came also to the conclusion that her delightful journey from Palermo to Messina was not robbed wholly of its pleasures because of the camera which she carried.

THE mysterious "Zutka" was driven from the Hippodrome last week to the City to be photographed. "Zutka" had been packed nicely away in his three-foot-long box and set on the top of the cab, while one of his staff occupied the cab. There seemed no reason why anyone should ever find out that the mystery was there, but at Fleet Street—

of all places—a remarkable thing happened, right under the windows of the newspaper offices too! The throng in Fleet Street suddenly became aware of a couple of yellow stilt-like legs appearing in the air over the cab, then other parts of a body, which was immediately identified as “Zutka’s.” The lid had come off the box! The gentleman inside the cab did what he could to put things right, but all to no purpose, so the cab and the figure had to remain exposed to the interest of hundreds of people for nearly a quarter of an hour. An unfortunate business altogether. But are there photographers in the City?

The Ideal Portrait Lamp.—Regarding the Ideal Portrait Lamp, which we noticed in these pages on its introduction last winter, Messrs. Houghtons Limited, of 88 and 89, High Holborn, London, W.C., write:—It is now some months since we first had the pleasure of introducing to your notice the Ideal Portrait Lamp for studio and at home portraiture and group work. As the season is again arriving when this work is more largely practised than at any other time of the year, we take the liberty of again drawing your attention to the lamp. A large number of photographers have now had the lamp in use in their studios, etc., for a long period, and the copies of a few testimonials which we hand you herewith will show you what is the opinion of those who have had practical experience in its use. Messrs. Gardner and Co., of 36 and 40, West Nile Street, Glasgow, have a stock of these lamps, and will be pleased to demonstrate same to those interested.

SOUTHAMPTON Camera Club.—At the Philharmonic Hall, on the 14th inst., before a numerous company of members and friends of the above club, Mr. S. G. Kimber, the hon. secretary, delivered an admirable lecture on “The Cathedral of Winchester,” beautifully illustrated with one hundred charming lantern slides. Commencing with a reference to the remote antiquity of the city of Winchester, developed in myth and mystery, the lecturer gradually brought his audience to the time when it became the chief city of the land, and briefly noted the many important functions and ceremonies enacted there and within the walls of the grand architectural pile forming the object of the discourse. Entering the Close by the King’s Gate, the route taken was via the Deanery and south side to the west front, all of which were graphically described, with emphasis on the fact that architecture of the 11th, 12th, 13th, and 16th centuries is here represented. Entering the cathedral at the west door, the beautiful nave, aisles, minstrel gallery, and most important monuments and memorials were adequately described and portrayed; and then an advance was made into the vitals of the structure, the place where St. Swithin’s shrine once stood being pointed out. The tombs and monuments of many important personages, including those of Isaak Walton and Bishops Edyndon, Wykeham, Fox, Beaufort, Gardiner, Waynesflete, Wilberforce, Brown, etc. The triforium and clerestory were reviewed, and the organs, both ancient and modern. The interior of the unique choir—with its Norwegian oak stalls, so beautifully carved; its unequalled grand High Altar screen; its tomb of Rufus, and mortuary chests, containing the remains of several Saxon and Danish kings—was brought specially to notice in a most instructive manner. Mr. Kimber next dealt with the chapel and tomb of Bishop Langton and with the Lady Chapel. The chair used by Queen Mary when being married to Philip of Spain in 1554 by Bishop Gardiner in the nave of the cathedral was portrayed, and the fact mentioned that it may now be seen in the Langton Chapel. The lecturer next paid attention to the north transept, which is of Norman construction, of an imposing and massive character, and then to the crypts, which were pleasingly described and illustrated. He then spoke at length of the upper and less frequented portions of the building, referring to the massive Norman passages, which have existed for upwards of 800 years, and seem to be quite capable of lasting another 800 years. Lastly, Mr. Kimber spoke of and illustrated the forest (as he rightly termed it) of timber over the vaulting of the nave and supporting the huge roof, and with a fine panoramic scene from this spot the lecturer finished his discourse, which had been listened to with great appreciation throughout. Mr. Wm. Burrough Hill (the president of the club), who occupied the chair, in proposing a vote of thanks, deservedly eulogised the lecturer for his excellent contribution to the club’s winter programme, and said he hoped to hear the lecturer again, and would gladly place the large hall at his disposal for the purpose at any time. Mr. Kimber made suitable response to the hearty vote of thanks accorded him.

Correspondence.

- * * We do not undertake responsibility for the opinions expressed by correspondents.

THE GOERZ COMPETITION LANTERN SLIDES.

To the Editors.

Gentlemen,—I should be glad if you would kindly mention in the columns of your esteemed journal that there will be ready very shortly a collection of slides from the Goerz competition, which will be at the disposal of photographic societies. In addition to these the three other lectures, which have previously been circulating will also be at the disposal of secretaries, and probably another new lecture will be ready early in January.—Thanking you in anticipation, yours faithfully,

C. P. GOERZ.

1-6, Holborn Circus, London, E.C.
November 3rd, 1904.

PROBLEM No. 2.

To the Editors.

Gentlemen,—As a poor photographic assistant I am writing for your sage and fatherly advice. Although I have been in the profession for many years, first as an apprentice, and since as an operator, I find that owing to the low ebb to which our business has fallen, the large number of competent assistants seeking employment it is very difficult to obtain an appointment in which I can do as I like, and at the same time get as large a salary as could be desired. I may say, however, that I have a knowledge of the “preaching business,” having practised it upon my friends for several years, and I think I could on at it all right if my idea could be worked into shape. Can you recommend me to a nice little tabernacle, where I could exercise my talents and undoubted oratorical abilities. I should prefer the building to be lighted from the north side, so that I may utilise it as a studio for photographic purposes during the week, where I could photograph my flock and their friends. I should prefer a tabernacle with a lawn in front, so that I could photograph wedding groups and Sunday school treats, etc., on the premises. If you could render any assistance in this matter I should be greatly obliged. I may say that I have found the preaching business pay very well, and I must not say that as a man of business I should be able to manage the finances of both branches successfully. I should also be glad to refer the services of the chapel keeper as printer and general mucker round as my own family would rather undertake district visiting among parishioners, a branch of work in which they have more than average ability, especially at tea hour.

The P.P.A. I heartily agree with, and am quite agreeable to try my abilities through that association, but would be quite aware of it becoming the parson’s and photographer’s association though still

—Yours faithfully,
November 14th, 1904.

AQUA DILUTUS

PHOTOGRAPHY UP TO DATE.

To the Editors.

Gentlemen,—Enclosed find circular distributed in our town on Saturday last. Will you kindly inform me through your paper if the black and white carbons are a new art? Also the same inquiry applies to platinotype bromides. I should deem it a great favour if you can enlighten me on this subject; or is it simply business bluff, the same as the free use of his Majesty’s name? I think it plainly another move on the part of the professional-amateur who you so ably dealt with in a recent issue of the B.J.P.—Yours, etc.

November 10, 1904.

EUREKA

[We append the essential portions of the interesting circular enclosed by our correspondent. “Black and white carbon” may be a permissible term, but there is no such thing as a “platinotype bromide.” We hope the authors of the circular will take note of this.—Eds. B.J.P.]

“Having just commenced business, and having all appliances up in the profession for the most up-to-date work, we beg to state that we are in a position to execute the very best work in black and white

platinotype bromides, the three-colour process, etc. Also the best class of oil and water-colour paintings (any size), miniatures in ivory in gold and silver frames, etc., etc. Pictures framed in every style. Enlargements any size or style. Photo postcards and Xmas cards—a great variety to select from. Mr. —, having been chief operator to Mr. —, who just recently came under the patronage of his Majesty the King. This alone should convince our customers as to the superiority of our work. Our sole aim will be to give every satisfaction and prompt delivery of work submitted to our charge."

To the Editors.

Gentlemen,—We have been following with great interest your published letters on the subject of cheap photographers, and, as old readers of your journal, we beg to send you a specimen handbill of a photographer of —, and ask you to reply through the medium of your paper whether you think he is a fool to his own interests or if photography as an art is doomed. Another photographer of some thirty to fifty years' standing is doing the same kind of thing, and if he can keep up their large establishments and still live I am sure cannot but say these men are marvels to present-day photographers, and should have monuments erected to their memory after their decease.—Yours faithfully,

LIVE AND LET LIVE.

This is the bill to which our correspondent refers:—"Look here! Photos taken Day or Night. High-class photos at the following low prices: Cabinets, 12 for 7s., 6 for 4s., 3 for 2s. 6d.; Carte-de-visites, for 4s. 6d., 6 for 2s. 6d., 3 for 1s. 6d. Private Greeting Cards 1s. dozen, taken or copied from any photo. Enlargements from 4d. each, ready for framing."

(Replying to our correspondent's question, we do not think photography as an "art" (sic) is doomed because cheap photography is successfully practised. We ourselves were taken for ninenepe, and shillings and sixpence for three cabinets in the long ago; to-day, however, nothing less than the production of a Lewis, a Crooke, or a Macdonald would satisfy us. We live, learn, and (some of us) grow wiser.—Eds. B.J.P.]

FRANK McCLEAN, M.Inst.C.E., the distinguished astronomer and civil engineer, died last week at Brussels in his sixty-seventh year, having been educated at Westminster School, at Glasgow, and at Cambridge. Mr. McClean, after being apprenticed to Sir John Hawkshaw, the famous civil engineer, in 1859, became a partner in the firm of McClean and Norman, civil engineers, three years later, and was for some time engaged in important dock and railway work. After 1870 he devoted his energies mainly to astronomical study, establishing an observatory at Thurbridge Wells in 1874. For his photographic survey of stars in both hemispheres and other astronomical contributions he was awarded the gold medal of the Royal Astronomical Society in 1881. Ten years earlier he had founded the Isaac Newton Studentships at Cambridge. Mr. McClean was a Master of Arts of Cambridge, an LL.D. of Glasgow, and a Fellow of the Royal Society and of the Royal Astronomical Society. His father, the late Mr. J. R. McClean, R.S. M.P., was at one time President of the Institution of Civil Engineers.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted wholly without condition, expressed or implied, as to what appears in the text portion of the paper.

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

G. E. Clarke, Sandhurst Studio, Camberley, Surrey. Photograph of Mr. W. S. Stanley's Shop, Bagshot.
R. Wilkinson, The Studio, Hornsea, Hull. Two Photographs of the Old Hall, Hornsea.
G. Packer, 3, St. John's Terrace, Leeds. Photograph entitled, "Moonlight of Algiers."
R. Thirlwell, 21, Bridge Road, Stockton-on-Tees. Photograph of Stockton Football Team, 1904-5.

POSTCARD.—You will find your query dealt with in "Ex Cathedra."

G. B. (Croydon).—Expose the plates long enough to produce the reversed action of light, and develop in the ordinary way. The time necessary for the reversed action, which varies with different brands of plates, you can ascertain by experiment.

JOHN WICKENS.—As the work was done to your order, and you paid for it, the picture is yours, and we should say your name is rightly upon it, particularly as you did part of the work yourself. If the facts be as stated in your letter, we do not see what action can be taken.

ADDRESSES WANTED.—"INQUIRER" asks: "Could you please supply me with the names and addresses of a few German firms who print the coloured postcards?" In reply: We have no directory of postcard printers in Germany. Better put your query to one or other of the German journals.

EMULSIONS.—"F. G. W." asks: "(1) Can you please tell me what is the best book I could get upon emulsion making (in English), excepting Captain Abney's? (2) Is there a modern writer who treats especially upon collodion?" In reply: (1) There is no modern work, in English, on the subject, except that of Captain Abney. (2) No.

BOOKS WANTED.—"ECLENOFF" asks: "Could you kindly state the best book or books on photo-mechanical processes and photography as applied to printing, block-making, etc., and their prices?" In reply: "The Halftone Process," by Verfassers, 5s.; "Photo-lithography," Fritz, 3s. 6d.; "Photo-mechanical Processes," Wilkinson, 5s.

SAFE LIGHT.—"J. A. S." writes.—"Would you kindly tell me where I can procure the aurantia and rhodamine mentioned on page 1076 of the 'Almanac'?" In reply: The dyes mentioned are supplied by such houses as Hopkins and Williams, Cross Street, Hutton Garden. They may also be had, we surmise, through any of the photographic dealers.

FORMULÆ.—"A. M. M." asks: "Could you oblige by giving the formula for a very slow emulsion, such, for instance, as is used on the various gaslight papers now so much in vogue? I presume it is a bromide emulsion which is used on them." In reply: Mere formulæ—without details of working—is of little practical value. We should recommend you to get Abney's "Photography with Emulsions," you will learn a lot from that. The makers of the various gaslight papers do not publish the formulæ they employ.

GRADER.—"ENLARGING" asks: "(1) Where can I obtain a 'grader,' as referred to in Mr. Howard Farmer's paper in your issue of October 28, 'Progress in Enlarging'? (2) Kindly give your advice as to the most suitable grade for small portrait work." In reply: (1) Messrs. Penrose and Co., Farringdon Street, supply screens suitable for the work. (2) As we have not yet tried the system, we cannot say which will be the most

suitable grade for your purpose. Why not communicate with Mr. Howard Farmer on the subject?

GREEN TONES.—"PRINTER, MATTE C.C.," writes: "Could you kindly inform me if it is possible to obtain green tones on matte C.C. paper? I know of no maker of C.C. paper giving formula for green tones. My employer says he has seen some nice green tones, but I have never seen any, except on developed papers, such as carbon, bromide, and others. Shall take it very kindly if you enlighten me." In reply: We know of no method of producing green tones on collodio-chloride papers.

PHOTOGRAPHY IN AUSTRALIA.—"J. J." asks: "Can you give me any information as to professional photography in Australia? Are prices better, chemicals higher in price than in Great Britain; also, is the climate good for outdoor photography, or would there be an opening for a photographer to start business in a small way?" In reply: So far as we have been given to understand, photographic competition in Australia is quite as keen there, in some parts keener, than it is here. Chemicals are, we believe, higher in price. The climate is good.

TRICK PHOTOGRAPHY.—P. NIGHTINGALE writes as follows: "I am interested in trick photography, and I hear there has lately been a correspondence in your paper relating to Mr. Bourns, who professes to take spirit photos. I have recently had some sittings with him. Could you tell me when the correspondence was, which issues of your paper, so that I can, if possible, secure them, and whether there is any work dealing with this subject (trick photos)?" In reply: There was a good deal of correspondence in our columns on the subject of "Psychic Photography" between March and September this year.

COLOUR PHOTOGRAPHY.—"M. R. S." says: "I should be much obliged if you would tell me of any book which would give me practical instruction in colour photography. I do not want theory first as in Marion's 'Handbook of Photography in Colours,' but a book which will tell me:—(1) What camera is required. (2) How the negatives are taken. (3) How the final reproduction or print is obtained. Is it possible to print the negatives on litho stone and obtain prints in the way colour printing is done?" In reply: "Photography in Colours," by Bolas, Tallent, and Senior; or "Three-colour Photography," Baron von Hubl, are good works on the subject, and will give the information desired.

STUDIO QUERY.—"MORE LIGHT" says: "(1) Am in a fog as to the lighting of a studio which I have just bought, out of which I hope you will assist me. The studio had a top and side light of 12 feet both sides; have blocked out the light on one side. Would you advise my blocking out the top light on that side also, as the faces of sitters appear so very white, no light and shade? (2) There is also 6 feet of background end, blank, that is without top or side light. Should the sitter be posed clear of this blank? (3) The sitter faces N.W., what colour blinds would you advise?" In reply: (1) As you have blocked out one side light, you do not say why, we should say you would do well to also block out the top on that side. (2) No, they should be some little distance farther back. (3) A medium tint of green will be as good as any.

CARBON PROCESS.—W. H. G. AND SON write: "We have photographed five views, 12in. by 10in., in Kelly Den. These, we learn, are to be reproduced as panels, transferred and put on wood, in the cabin of a ship just building, named 'Den of Kelly.' The five views have been accepted, and customer writes to ask us to do two copies of each on the paper best suited for transferring to wood. This is exactly where we are at sea. We are quite willing customer should do the transferring, but we know not the kind of paper. Can you help us? The photographs are wanted at once." In reply: The best method of producing the pictures is by the carbon process, developing them on flexible supports, and then transferring them to the panels in the usual way. By the carbon process permanent results will be secured. If you read the notice that appears at the heading of this column each week, you will see that we do not answer correspondents by post.

SIZE OF POST CARDS.—D. IRELAND writes: "Having seen advertisement in your columns I asked Messrs. — and Co. prices and specimens of collotype cards to be made from subjects. They sent me some very fine specimens in different styles, one a full card; I returned with an order for two lots specifying particularly 'full card,' and paid in advance. The enclosed are samples of what they want me to accept. Apart from the wretchedness of the execution, they are not full cards as are the rest of my series, and I declined to accept them."

— and Co. say they 'think they are full card enough.' I have repeatedly asked them to execute the order in accordance with my instructions, but they take no notice. Will you kindly advise me what to do in the matter?" In reply: On measuring the cards sent we find they are the size allowed by the Postal authorities, namely $5\frac{1}{2}$ by $3\frac{1}{2}$ inches, so that they are to your order. In future, write on one side of the paper only, please.

LENS QUERY.—"GLAUCUS" says: "(1) Can you please advise upon the choice of a lens? I require a lens suitable for landscape cabinet heads and for groups, fairly rapid, F. 6 or F. 7; length of my studio is only 21 feet 6 inches. Are the following suitable?—Suter's Aplanat A, F. 6.3, No. 3, 11½-in. focus; Beck's Biplanat, series I, F. 5.8, No. 6, 11-in. focus; Voigtländer's U. Euryscope, series IV.a, F. 7, No. 2, 9½-in. focus. (2) Some years ago, I and seven others were taken in a wedding group; several of us now require additional copies, and I have written to the photographer to buy the negative or to make other copies, but can get no reply. Is he bound to sell negative or copies if required?" In reply: (1) In so short a studio the longest focus lens will be the best for large heads, the reason of the better perspective it will give. The shortest focus one will be the most suitable for groups. (2) The photographer is not bound to sell the negative. Probably he has not kept it and, therefore, is unable to supply copies.

TRAVELLING.—"MIDLANDER" writes: "A little time ago I entered into a contract to demonstrate and sell a certain 'gaslight paper' in the South of England. I was to receive a nominal salary, actual travelling expenses (fares only) and commission. When I agreed to these terms, I, in my own mind, settled that my journeys would take me anywhere within 100 and 150 miles south and west of London, but to my dismay, my employer declares that such towns as Torquay and Truro are included in the 'Southern Counties.' I am threatened with legal proceedings if I do not carry my contract out; employer having every advantage by my terms. Of course you will understand that these much longer journeys will be greatly to my detriment in every way." In reply: This is a question for a solicitor, as all will depend upon the agreement made. Truro and Torquay can scarcely be considered the South of England, but we should have thought that the wider your field of travel the better it would be for you in the end of commission.

VARIOUS QUERIES.—"STYLES" says: "(1) I have a batch of prints to mount on art paper, C.C. plat., etc., and have met with the usual difficulty of cockling, even when dried under moderate pressure; I have tried thin gelatine and secotone. Can you let me have a few practical hints? I have, of course, mounted them dry. (2) What are the most suitable subjects for the 'Romney' style of portraiture? Also could you give a brief outline of the style itself? (3) Re 'Cosway,' have you usually seen these with the head and shoulders draped? Is the draping necessary providing the subject is suitable? (4) Where could I see specimens, or obtain a print of the above and any other styles in vogue among the leading firms?" In reply: (1) The best mounting solution for the purpose, I know of, is that given on page 1,071 of the "Almanac." The Dry Mounting Company, Fetter Lane, have a system of mounting that entirely avoids cockling. (2 and 3) You had better study the works of these two painters, which can be seen at the National Gallery. (4) Better see the styles shown in the windows and showcases of leading firms.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1905.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-fourth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,604 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1905 will also consist of 25,000 copies, and will number 1,612 pages, thus constituting the volume the largest yet published.

The following are some of the important features of the forthcoming volume:—

1. The frontispiece will be a portrait study specially produced for the Almanac by Mr. Furley Lewis (Medalhist at the Royal Photographic Society's Exhibition, 1903).
2. The first editorial article, which deals with "The Present and Future Position of Photography," discusses the probable growth and expansion of all branches of modern Photography.
3. The second editorial article supplies a succinct illustrated history of the BRITISH JOURNAL OF PHOTOGRAPHY and its Almanac ever since their foundation.
4. Important articles and papers by the following, amongst many other well-known photographic writers, are included in the volume:—

Abney, Sir W. de W., C.B.	Dormer, J.	Hartmann, Dr. J.	Nelson, E. M.	Salisbury, J. W.
Baker, T. Thorne.	Duncan, F. Martin.	Henderson, A. L.	Neubaus, Dr.	Salmon, P. R., F.R.P.S.
Baldeck, J. H., F.C.S.	Dunmore, Edward.	Hepworth, T. C.	"Ons."	Selby, H.
Barker, J.	Dunmore, G. H.	Hett, Charles Louis.	Payne, A., F.C.S., F.R.P.S.	Slater, P. J.
Bentley, B. F., M.A., F.L.S.	Everitt, Philip.	Hodges, John A., F.R.P.S.	Perkins, Rev. T., M.A.	Smith, J. H.
Bird, J. J. S., B.A.	Foxlee, E. W.	Joly, Dr. J., F.R.S.	Pike, J.	Sutton, C. T.
Blesbrook, G. Van.	Gamble, William.	Jourdain, Philip E. B.	Piper, C. Welborne.	Tilfor, J.
Bolas, Thomas, F.I.C., F.C.S.	Goodchild, Rupert.	King, Horatio Nelson.	Procella.	Wall, E. J., F.R.P.S.
Brosig, P.	Gower, H. D.	Leisk, J.	Rheinberg, Julius.	Wallace, Robert James.
Brown, G. E., F.I.C., F.C.S.	Graves, Frederick.	Lockett, A.	Richards, T. W.	Walmsley, W. H.
Channon, H. J.	Hackett, J. T.	Mills, Edmund J., D.Sc., F.R.S.	Rohr, Dr. Moritz von, D.Phil.	Watkins, Alfred.
Clifton, Edgar, F.R.P.S.	Harris, Geo. T., F.R.P.S.			Valenta, E.

5. Numerous illustrations, including Portraits of many Celebrities in the Photographic World.
6. An exhaustive Review of recently introduced Photographic Apparatus.
7. Sections devoted to Practical Points; Epitome of Progress during 1904; Formulæ; and a great mass of Miscellaneous Information.

UNFAIR COMPETITION IN THE PHOTOGRAPHIC INDUSTRY.

UNDER the above heading, we, in our last issue, as a translation from the "Photographisches Wochenblatt" gave what purported to be a report of a case that had been before the Law Courts in Germany between Westendorp and Wehner of Cologne and Ilford, Limited, and in another part of the paper made some remarks under the heading "Ilford and German Injustice." Since then we have received a letter from a gentleman in Germany, which we publish below, explaining that by an unfortunate error it was a complete mis-statement of what had really taken place, and that the decision there, instead of being one against Ilford, Limited, was completely in their favour, and against Westendorp and Wehner, who were the ones found guilty of an improper infringement of the ticket and trade-mark of Ilford, Limited, and condemned in damages and costs accordingly, with an injunction restraining any further continuance of the offence.

The error in the German report seems to have originated in this way:—Ilford, Limited, had been the ones originally taking the proceedings in the German Courts as plaintiffs against Westendorp and Wehner as defendants. The decision in the first Court was completely in favour of the plaintiffs, and thereupon the defendants appealed. On such an appeal apparently the appellants, though defendants in the original proceedings became appeal plaintiffs, and the original plaintiffs appeal defendants. The Appeal Court completely confirmed the previous decision in favour of Ilford, Limited, but by the names plaintiffs and defendants being thus confused the German reporter made the mistake of making it appear as if the appeal plaintiffs had been the ones who had succeeded instead of the original plaintiffs.

We extremely regret that we should have been the means of giving any further publication to this completely erroneous report of the case, exactly reversing the real decision, and still more that, based upon that report, we should have made the remarks we did, and which we admit were quite unwarranted. We offer our fullest and sincerest apologies, with every expression of regret, to Ilford, Limited, for this unfortunate occurrence, and hope it will now be quite understood by our readers that instead of there being any pretence of a ground of complaint against Ilford, Limited, or any foundation for the unjust imputations made upon them, they have been the ones entirely in the right in the matter, and so completely so, that when taking proceedings in German Courts against German subjects, they both, in the Court of first

instance, and again on appeal, obtained decision in their favour, with substantial damages.

The following is the letter we have received on the subject:—

To the Editors of the BRITISH JOURNAL OF PHOTOGRAPHY.

GENTLEMEN,—Your last number contains an article reproduced from the "Photographisches Wochenblatt," and a commenting article, "Ilford and German Industries," which both are based on wrong information. What really happened was just the contrary. The Westendorp and Wehner Company has been fined for having used the "Milford" label, which has been deemed to be an imitation of the Ilford Company's legal label Ilford with steamships.

In the next number of the "Photographisches Wochenblatt" you will find a rectification, unfortunately it was too late for last number; now as I was myself who drew Mr. Gaedicke's attention to the fact that this article really must be wrong, I will do still this for my friend Gaedicke that I give you some details how this mistake could happen. Mr. Gaedicke has been the victim of his correspondent who made for him an extract of the sentence, but was not sufficiently versed in legal language to understand the Law Courts' slang. It is a peculiarity of these sentences that the names of the parties only are stated at the head of the sentence, later they only appear as "plaintiff" and "defendant." Now in the first sentence Ilford was plaintiff, Westendorp and Wehner defendant, the latter were condemned and appealed. In the Appeal Court they call the appealing party "Berufungskläger," i.e., "Appeal Plaintiff," the other one "Appeal Defendant"; thus the sentence of the Appeal Court surely will begin "In Sachen Westendorp und Wehner Berufungskläger contra Ilford, Ltd., Berufsklägte," and in the sentence The Ilford Company will be called as well "Appeal Defendant"; if they speak in the argument in the Appeal Court of "plaintiff," they mean the original action and vice versa. Now this reporter did not distinguish between the terms Appeal Plaintiff and Plaintiff, and so resulted the dreadful Gallimathias in the "Photographisches Wochenblatt."

Most probably you will have a rectifying letter from the Ilford Company for next number, and I hope this letter will arrive in time to show you that it was only a mistake that converted the fact into the contrary and enable you to explain to your readers how this mistake could happen.

Yours most respectfully,

Luxembourg-Gare,

F. DYCK.

19th November, 1904.

EX CATHEDRA.

Chloride of Mercury Solution.

draw attention to the observations of a French chemist which were communicated to the Chemical Society of Paris recently, and appear in the current Bulletin of the Society. M. Vittenet finds that a dilute solution of mercuric chloride and ammonium chloride is readily decomposed by a solution of bicarbonate of lime, the well-known clear liquid which results from the prolonged passage of carbon dioxide through lime water, or which may be said to be represented by the average "hard" water. A precipitate is produced of yellowish-white colour, and, though we will not follow M. Vittenet through the list of compounds which he surmises the precipitate may be found to consist of, we may say that it is one of the chloro-amido bodies which are so readily formed by mercury. Though named by the author only in connection with the weak solutions of mercury used as bactericides, the change may well explain some of the uncertainties and irregularities of mercurial intensification. The remedy, or rather the preventive, is to use sodium chloride (common salt) instead of the ammonium chloride, or to employ well boiled water or distilled water. We would add to these recommendations of M. Vittenet's still another, and that is to make the mercuric solution without the assistance of solvents like these alkaline chlorides. There is absolutely no need to go beyond the plain solution of the chloride, which is most advisedly made as follows:—An ounce of mercuric chloride is dissolved in 10 oz. of nearly boiling water, the liquid cooled, and any bathery crystals allowed to settle, which they quickly do by reason of their great weight. The liquid is then poured off, and about 30 to 40 minims of strong hydrochloric acid added to it. The solution is then ready for bleaching the negative, and will retain its properties for an indefinitely long period if kept away from a strong light.

* * *

The Naturalist-Photographer.

We have always regarded with a kind of reverential awe those persevering men who, camera in hand, will track the wild beast or bird to its lair, in spite of every personal discomfort. To hang on by one's eyelids to a beetleling crag, with the wild waves beating on the rocks hundreds of feet below, with the sole reward of a negative representing the nest of eggs of a sea-bird, seems to us to be an astonishingly desperate proceeding, nor can we understand the bliss of lying for hours at full length in a ditch full of dirty water in order to photograph the giddy tadpole in the bosom of its family. It is well that there should be unselfish men, who will thus sacrifice their own comfort for the benefit of science. They are naturally very few in number, and we can hardly hope to keep up the strain for many generations. Happily we need have no anxiety on this point. In fact, there will no longer be any need for the naturalist to put himself to any inconvenience at all, so far as the birds are concerned, for these obliging bipeds, no doubt seeing what a craze there is for photographing them, are leaving their native haunts and are making themselves at home in the London parks. Why sling yourself over a

perpendicular cliff at St. Kilda's to photograph a frightened gull when the same bird, tamed and civilised, will pose for you on the grass at St. James's Park? Why stalk the gaudy kingfisher through morass and quagmire "far from the madding crowd," when it will come and eat crumbs out of your hand on the banks of the Serpentine? "Can these things be true?" asks the incredulous reader, and we refer him for answer to certain letters which have recently appeared in the *Times*. One of these, commenting upon the circumstance that wild birds, once having screwed up their courage to face a flight to London, quickly learn to treat human beings with indifference, points out that the wood-pigeon, one of the most timid of birds in its native wilds, will scarcely move out of the way of the Metropolitan perambulator. The same with the dabchick, and as to the kingfisher, three of these gaily-dressed birds have made themselves quite at home in St. James's Park. The brown-headed gull is another bird which frequents this resort of fashion, and comes there in huge flocks. Other parks which have ornamental waters are favoured in the same way, but St. James's seems to be the sanctuary generally chosen by the strangers, and in due time, no doubt, it will come to be regarded as a huge natural aviary.

* * *

Gas and the Photographer.

There is a general impression among those who have not acquired the habit of looking much below the surface of things, that gas as an illuminant has had its day. They see around them streets and shops brilliantly illuminated by electricity, and at once come to the conclusion that this healthful and pleasant light is destined to extinguish all others. A visit to the International Gas Exhibition, opened on Saturday last at Earl's Court, would quickly dispel this illusion, and would show that the newer forms of lamps have the appearance and nearly all the convenience of the electric glow lamp at one tithe of its cost. But what we were chiefly concerned with in looking through the exhibits was the possible application of gas lighting to the requirements of the photographer, and we may at once say that we were disappointed in our quest. As far as we could ascertain, not one of the exhibitors had troubled himself to cater for the photographer. The most noticeable feature of the exhibition is the total abandonment of the old forms of "fishtail," "batswing," and other burners in favour of the incandescent mantle. Not one of the old burners is in evidence, and the mantles are everywhere. And what will especially appeal to photographers is the great luminosity of some of these lamps. In one corridor is a row of lamps, each furnished with two burners of 500 candle-power. Each globe, therefore, sheds a radiance of 1,000 candles, a brilliance which was formerly associated only with the limelight, or the electric arc. These particular lamps are fed by gas under a pressure of 16 in., the extra pressure being secured by a double action pump worked by a small gas engine, the entire apparatus being of the most compact kind. The light from the incandescent mantle is of actinic quality, and this form of light seems to be in every way fitted for studio use in places where artificial illumination is required, and where electricity is not available. At this exhibition the inverted gas mantle is much to the fore, and the fittings made for it are most artistic. Here, again, we have a possible aid for the photographer which seems to have been quite neglected by the makers. A lamp of this kind, throwing a downward light, would, if suitably protected by a non-actinic screen, make a most admirable light for developing negatives by, while with an orange screen it would be first-rate for developing enlargements.

Too often the photographer, working in a cramped space with the light immediately in front of his eyes, is heavily handicapped, and he would be the gainer by using a light like this suspended above his head. Of course, this has long been done with the electric glow lamp, but in penning these notes we have in our minds the many places where electric mains are not. The photographer is also interested in a minor degree in gas for heating purposes. In this direction no advance seems to have been made, and there is certainly much room for improvement.

* * *

Decrease of Fog in London.

Those who delight in photographs of a foggy nature, or those of fogs, such as "the park railings in a fog," Westminster or other London bridges in a fog, etc., etc., had plenty of scope for their cameras last week. On the other hand, professional photographers found their lot a hard one with the continued fogs. However, it may be some consolation to the latter to know that the fogs we get now are not so many or so bad as they were many years ago. At the last meeting of the Royal Meteorological Society a paper was read by Mr. F. J. Brodie entitled "The decrease of fog in London during recent years." Statistics were quoted showing the number of days on which fog was experienced in London during the past thirty-three years. From these it seems that the monthly averages for this period showed that December is the foggiest month of the year, and after that comes November, the next in order being January and October. During the year there is an average of 55 days with fog of more or less intensity, and the worst year of the whole series, it seems, was 1886, with fog on 86 days. The clearest year was 1900, when it occurred on 13 days only, the number being only one-half of that recorded in the next best year (1903). The decrease in the prevalence, and also in the intensity, of London fogs was attributed by the author of the paper to a lessening of the smoke evil, due to four contributory causes—firstly, to the efforts made by the Coal Smoke Abatement Society in enforcing the laws by which factories and other large works are required to consume their own smoke; secondly, to improvements in the forms of domestic grates; thirdly, to improved forms of lighting, the old-fashioned gas-burner being largely replaced by incandescent ones, which emit far less smoke, and by incandescent electric light, which emits practically none at all; fourthly, to the largely increased use of gas stoves for heating and cooking purposes. In conclusion of his paper, Mr. Brodie said: "The position of London on the banks of a large river is, of course, eminently favourable to the development of fog and mist; so that, from a purely geographical and meteorological point of view, the position of the metropolis is, we fear, incorrigible." With a cleaner air, however, there is little doubt that fogs would diminish in frequency; and, even when they did arise, the vapour particles would not be coated and impregnated as they now are by the pestilential products arising from an imperfect and wasteful consumption of fuel. Many of our older readers will be able to recall to mind the dense "pea-soupy" and choking fogs we sometimes had during the winter months some twenty or thirty years ago. We have, it is true, occasionally fogs of a similar type now, but our older readers will bear us out in saying that they are in a more dilute form than in the olden times. Yet we hope for a still further mitigation of the evil.

CAN THE STEREOSCOPE BE REVIVED?

THE advocacy of stereoscopic photography has appeared up to the present time very like the traditional whipping of a dead horse, for, though some photographic societies always include among their schedules of prize competitions one or more classes for stereoscopic views, the competitors

are usually confined to a small band of workers—we know of cases where the prizes have been withheld through there being no competition. Even this small band, as far as our own observation goes, we regret to notice, diminishes rather than increases in numbers, and the ratio approximately represents the interest that photographers in general take in a beautiful process, to which, of all other photography is so especially applicable. Why such indifference should persist is a question to which it is not easy to give a satisfactory reply, especially when it is remembered what an absolute rage stereoscopic work once attained to. It arrived at a wonderful popularity with marvellous rapidity, but its wane was almost more rapid than its rise. It is impossible for any one not living at that time—about forty years ago—to have any conception of the popularity of the stereoscope; there was scarcely a house in the land, from the palace to the cottage, without an instrument of some sort and its attendant views. After a while, people became indifferent—"Oh, I have seen them before," was the usual cry; prices were lowered to induce further purchases, "revolving stereoscopes" were designed to obviate the trouble of changing views; but still the indifference increased. Then came the introduction of coarse, not to say indecent, subject views, and, in a wonderfully short time the demand collapsed, and an utter slump set in which has continued ever since, with the exception of a few spasmodic outbursts. By a sort of tacit conspiracy the stereoscope and its views were everywhere relegated to a cupboard in the attics. The word stereoscopic as applied to a picture was in frequent use to signify roundness and solidity of effect in a single picture, and everyone knew what it meant; but a generation has arisen—nay, two generations—who have never even seen a stereoscope, and to whom it is nothing but a name. Advantage was taken of this prevailing ignorance a few years ago by a small band of business experts, who seemed to be travelling the country through. They worked most of the towns of any size, and made such a scoop as would make an ordinary business man's mouth water. Orders for £2, £5, £10 worth of views were common. They carried a stock of views and a cheap skeleton stereoscope with a fancy description and an equally fanciful price. It was so easy to get enthusiasm out of a man who had never looked through a stereoscope in his life, nor ever, perhaps, heard of one. They roused the enthusiasm and pocketed the dollars.

The point we wish to make, and to which we have endeavoured to cause our remarks to lead up, is this: If, as we have just shown, it has been possible to create a demand in certain directions, and to make money out of it, does it not seem probable that a combined effort among photographers and dealers to interest and inform the whole of the public, and not a limited selection, would meet with success? Among our non-technical friends we could name half a dozen who have never looked through a stereoscope, or even seen a stereoscopic view. The open form of the instrument now in favour lends itself to ready viewing, and changing views, though the joys of a transparency view such as forty years ago Ferrier and Soulier produced, and which were retailed at five shillings each, are best realised with a closed-in stereoscope. It is the transparency type that is most in favour among amateur photographers; and those who produce them usually are—and have justification for it—enthusiasts in their hobby. Process blocks have by degrees reached such a point of perfection that it would be quite possible to make them fine enough to prevent any coarseness of texture being discernible, even under the slight magnification of the twin lenses, and with stereo views from process blocks an immense number could be had for a small price, and still leave a good margin of profit.

Side by side with these, of course, would be on sale direct prints, bromide or P.O.P. or collodion, or transparencies on glass or celluloid.

But the greatest spurt of all would be given by a general introduction of a postcard stereoscopic view, in bromide or print-out. If these were made and printed on stiff board, and stereoscopes stocked for sale at every shop where the views were dealt in, there would be such a revivification of the demand for stereoscopic views as to remind one, if only distantly, of the great boom of 1862.

COLOURED PICTURES ON THE LANTERN SCREEN.

DURING the infant years of photography, when the optical lantern was little more than a toy, coloured pictures were all the rage. Such lanterns as were used for public exhibition purposes were rather ponderous in build, for the condensing lenses would measure a foot in diameter, and everything else had to be in proportion. The reason for this was that the pictures, drawn and coloured by hand, were some 8 in. or 9 in. across, for in less space the artist could hardly be expected to find room for that elaboration of stippled detail necessary to the work.

Then came the photographic slide, with its wealth of microscopic detail which put the artist to shame, and a 3-in. picture and a 4-in. condenser at once reduced the weight and the cost of the lantern, so that it quickly became popular. The painter of lantern pictures had seen his best days, and the art—so far as large pictures, hand-drawn and hand-painted, were concerned—ceased as an industry. Coloured lantern slides came to be tabooed, and it was a hackneyed remark, constantly heard, that a photograph coloured was a photograph spoilt. Like many another hackneyed saying, this was not altogether true, and was probably started by some one who had only seen the worst kind of slide painting. In the hands of an artist who cared to master the technical difficulties of applying colour to such small surfaces, a lantern slide would be immensely improved by the process. Later on, when aniline tints came to be employed, and the process of painting simplified, first by the Japanese, and subsequently by several workers in this country, the coloured lantern slide once more came to be tolerated. Now that such pictures can be produced in a more scientific manner by the trichromatic processes, lantern pictures in colour are becoming all the rage, and we may reasonably look forward to a revival of interest in lantern exhibitions on this account.

The principal reason why the coloured lantern slide has been hitherto treated with contempt is because the colouring has generally been so very bad. It was sufficiently good for the children, for bright colours are pleasing to little folk, and gaudiness with them is not a term of reproach. Skies are sometimes blue in Nature, but they were always blue in lantern pictures, *very* blue—*Prussian* blue—and the trees also were *very* green, and generally of that arsenical green never seen in natural trees. The reds, yellows, and other tints of a secondary nature used by the slide painter were equally gorgeous in hue, and were slapped on to the picture regardless of truth and discretion. The fault was with the public; they would not pay more than a certain sum for a coloured slide, and the dealer could not afford for that sum to engage the services of competent colourists. The best dealers would say, as they say to-day, "Pay me a fair price and you shall have well-coloured pictures."

The most effective coloured photographs ever shown were without doubt those exhibited by Ives in his "Kromskop," and those projected by him on a screen by means of a

lantern built on the same general principle as the "Kromskop." But the pictures had the great disadvantage of being extremely limited in size. With a powerful arc-light the pictures could not be effectively shown more than 4 ft. in diameter. This was good enough for a room holding 100 people, but quite inadequate for a large hall. The same objection applies to the very beautiful pictures shown by Sir William Abney at the Camera Club the other night, with an apparatus somewhat like that of Ives. The one arc-light split into three beams to serve the three positive images with their colour filters lost so much of its radiance in the process that the pictures had necessarily to be of small area, and even then many of the spectators crowded close to the sheet in order to appreciate the beauties of the pictures, which otherwise they would have lost. We fear, therefore, that this trichromatic method of showing pictures is not suitable for public exhibition, but must be confined to the studio or laboratory. Ives's trichromatic lantern has for a long time been on the market but for the reasons stated is not often seen in the lecture halls.

The simpler method of superposing three stained positives upon one another and binding them up as one lantern slide, as practised by Sanger Shepherd and by Lumière with such success, has a far larger number of adherents, and is being practised by many workers with good results. And as apparatus and methods of working get simplified, as they always do by a sort of evolutionary process, this system of obtaining coloured pictures for the lantern will grow in favour.

There are, however, numbers of persons in this world who hate to take trouble about anything; they will look at a good process like this, will shake their wise heads, and will say: "No, life is too short." The bare idea of taking three negatives and three positives to produce one lantern picture, to say nothing of the three staining operations, frightens men of this sort, and they will have none of it.

Hence it seems to us that there is scope for hand colouring of lantern slides, of a better kind than we have of late years been accustomed to, and in such work many students of our art schools might find a profitable outlet for their energies. For many good colourists are turned out year after year by these schools, who find the greatest difficulty in finding work. Possibly many of them have mistaken their vocation; they may not possess that gift of originality which fits them for illustrating books and periodicals, but at the same time they have a keen sense of colour, and could, when once the technical difficulties were mastered, turn out admirably coloured lantern slides.

That such work can be carried to the highest pitch of artistic perfection is proved by the Japanese examples to which we have already alluded. We also remember that the "Travelogues" at the Queen's Hall last year were illustrated on a big scale by excellent coloured pictures. But the most recently shown pictures of this kind are, perhaps, the best of all. We mean the photographs projected by the lantern at the Coronet Theatre, and more recently at the Camera Club, illustrating the architecture and art treasures of St. Peter's and the Vatican. These splendid pictures are by Signor Inguibert, who must have devoted many years to their production. The projected pictures measured, at the Camera Club, 18 ft. by 12 ft., the largest screen which the room would accommodate; but in spite of the great magnification, and the closeness of the spectators to the sheet, there was no sign of flaw or blemish in any of the photographs. The colouring of the landscapes was quite true to nature, while that of the interiors of the palatial rooms at the Vatican was so perfect that one seemed to be looking inside the apartments themselves rather than at a painted picture. The original slides, we learn, measured 9 by 12 centimetres,

i.e., a trifle larger than the familiar quarter-plate. This increase of area over the usual lantern slide, the opening of which does not measure more than $2\frac{1}{2}$ in., is distinctly in favour of the colourist, and it becomes a question for consideration, if coloured slides are coming once more into vogue, whether it would not be better to increase the area of our pictures. The change would not be easy, and would possibly be resented as greatly as a change of pitch in musical instruments, for it would necessitate so many alterations. Still, very good brush work can be done by a competent hand on a slide of the standard size. From the warm reception which the Italian pictures met with, even by such a conservative body as the Camera Club, it is clear that coloured slides are no longer regarded as "photographs spoiled," provided that the colouring is artistically done, and the fact should be noted by those whom it may concern.

THE Committee of the Gloucester Public Library have decided to commence the collection of photographs of objects of interest situated in the County and City of Gloucester and the neighbourhood, as a means of securing records and supplementing the existing collection of printed matter relating to the county. Promises of assistance have been received from the Gloucestershire Photographic Society, the Stroud Photographic Society, and the Bristol and Gloucestershire Archaeological Society. The proposal has also been received very favourably by the Council of the Cotteswold Naturalists' Field Club, who have decided to bring the matter before the members. The committee hope to obtain the help of all persons interested in the historical features of the district, and will welcome the contribution of prints. There is no stipulation as to size of plate, process, etc., and the Committee will arrange for and bear the cost of mounting; if possible two copies of each photograph should be contributed. Those who may have negatives of interest which they would allow to be reproduced for the purpose of the collection, but have not time to make prints therefrom, can help by communicating the subjects they represent. The following subjects are suggested as being within the scope of the collection:—Churches (interior and exterior), ecclesiastical ornaments and fittings, domestic architecture, village crosses, stocks, old furniture, early forms of domestic utensils, vehicles and agricultural implements, the physical features of the county, dress and customs, and all objects of general archaeological interest.

A PARISIAN Tragedy. — According to a Paris correspondent, a tragedy, which recalls one of Edgar Allan Poe's most notable stories, has just been enacted near the Vincennes Gate. Jules Hardouin, an old showman, had conceived for Abraham Franck, who followed the same calling, a violent hatred. Franck was engaged in selling photographs at the fair on the Boulevard. Richard Lenoir and Hardouin invited him to pay them a visit. "I will initiate you into a new photographic process invented by an American, who is a friend of mine," he said. "The invention concerns the employment of radium and X-rays. You will make a fortune by it. You will find me a real friend, for I will give you the secret of the invention. The American will exploit the patent abroad, but you can work France." Franck smiled at first, but eventually allowed himself to be tempted, and on Saturday morning he appeared at Hardouin's wooden shanty. "You are early," said the old showman. "The American is not here, but his absence does not matter. Keep perfectly still, close your eyes, and do not move." Hardouin then fastened a high board, furnished with rings, to the wall, and invited Franck to stand against it. Instantly rope was passed through the rings, and Franck found himself bound. Hardouin next took a razor and a revolver from a black box. "Choose," he said. "How do you wish to die? By the blade or by the bullet? You made me suffer a long time, but the hour of revenge has struck for me. Commend your soul to God." A shot rang out. The bullet grazed Franck's ear. He shouted for help and made frantic efforts to free himself. The rope proved to be rotten and broke, and Franck, seizing hold of the revolver, snatched it from the old showman's hand. He belaboured the skull of Hardouin with the weapon until the latter escaped, covered with blood. The neighbours, seeing him pursued by Franck, interfered and disarmed the pursuer. Hardouin returned to his house, and a few moments later another shot was heard. The madman, for mad the old showman was, had blown out his brains with a carbine.

SOME NEW RESULTS WITH RESPECT TO THE PRINCIPLE OF THE CONSERVATION OF ENERGY.

1.

OF late years, the photographic method used in the discovery of the Röntgen, Becquerel, and Curie radiations have, so to speak, forced this important branch of physics on the notice of photographers. And the discovery of radium, which arose from these researches, is apparently not incapable of applications in photography. Accordingly, it seems to me desirable in view of the fact that the properties of radium seem to necessitate the modification of some of what are regarded as the fundamental principles of science, to discuss these principles. Such a discussion is, more especially at the present time, indispensable for the scientific photographer. Indeed, it would be remarkable if it were not really to be expected that the progress of photography has required a greater and greater knowledge of subjects which appear at first sight without the province of photography. Without speaking of the rather extensive optical and mathematical knowledge required for the proper understanding of the photographic lens, we need only think of Lippmann's method of colour-photography to agree that a thorough knowledge of the wave-theory of light is essential for the scientific photographer.

Thus it has appeared to me to be useful to give the modern views on such subjects as the conservation of energy and the atomic theory in this periodical. The doing of this afforded me particular pleasure since I succeeded, about ten months ago, in remarking a fact about the principle which, to my knowledge, had not hitherto been remarked. This, together with other investigations, is of a mathematical nature, and has appeared in the "Quarterly Journal of Mathematics"¹ but here I shall try to explain my remarks in, as far as possible, non-mathematical language.² I have brought the remark in here, for there results from it the fact that the principle of the conservation of energy is not subject to the restriction which has hitherto been tacitly made.

In the first part I have explained, also in language as non-mathematical as possible, the nature and use of the principle in question; and I think the line of distinction between what is fact and what an arbitrary, though it may be a natural hypothesis—which latter may be almost expected to be ultimately contradicted by facts—is sufficiently emphasised. This is not done in some explanations of the principle, and is, I think, done in the best manner if we regard the principle of the conservation of energy as what may be shortly but mathematically expressed as *one* (we require, in general, at least two and may require four, six, . . .) of the "integrals" of the equations of motion.

We are accustomed to divide physical science into the departments of mechanics, heat, electricity, and so on. Of these that branch of natural knowledge known as mechanics is the oldest, and early (1788)³ reached a certain completeness which has not yet been equalled by any of the other branches. It was in mechanics that the first general propositions were arrived at; thus, that known as the principle of the "conservation of *vis viva*" was discovered, in a very general form, and applied by Huyghens in 1673.⁴ To explain this principle, we will begin by considering the simple case of a heavy body moving under the action of gravity near the earth's surface.

¹ "On the General Equations of Mechanics," *Quart. J.*, 1904, pp. 61-79.

² The formulae, for the most part, only require that elementary mathematical knowledge that every one possesses, and detailed reference for all mechanical concepts used, is made to the works of Mach; undoubtedly the clearest on such questions.

³ This is the date of the publication of the first edition of Lagrange's "Mécanique Analytique." In this work, the problems of mechanics were all given in an analytical (purely mathematical) form, and, though in many important cases the facts were not accurately formulated by Lagrange (e.g. the principle of "Least Action"), Lagrange first gave analytical mechanics the form it has to-day.

⁴ On the part taken by Galileo in the development of this principle, see Mach's "Die Mechanik in ihrer Entwicklung. . . ." 4th ed., Leipzig, 1901, pp. 148, 201, 266. Cf. pp. 177-182 (on the Huyghens).

When a body falls freely, the velocity continually increases, and Galileo found, by a guess followed by an ingenious experiment,⁵ that the final velocity (v) is proportional to the time of falling (t); or

$$v = gt \quad (1)$$

where g is some constant quantity. The space fallen through (s) from rest, Galileo also found by a process⁶ which is preserved in elementary works on mechanics, and which is, in reality, an integration of the above differential equation?

$$\left(v = \frac{ds}{dt} \right), \text{ to be } s = \frac{vt^2}{2} \quad (2)$$

Here the constant g is now called the "acceleration," and we have⁸

$$g = \frac{d^2s}{dt^2}$$

a differential equation which implicitly contains all Galileo's researches on falling motion.

From (1) and (2) now, by eliminating t , we get the relation between s and v :—

$$2 \quad gs = \frac{v^2}{2} \quad (3)$$

The principle of *vis viva*, now, is expressed in (3), which was extended by Huyghens to the case of many connected bodies. Huyghens had not, of course, Newton's conception of "mass,"⁹ but, supposing that we have, (3) can be written

$$mgs = \frac{1}{2} mv^2 \quad (4)$$

We now call the left-hand side the "work" (U), and the right-hand side the "kinetic energy" (T); and (4) is the principle of the conservation of *vis viva* for a single body. For many bodies under any forces (not merely gravitational, but as generalised by Newton) we write (as is evident to a mathematician):

$$\frac{1}{2} \Sigma mv^2 = \Sigma \int F \cdot ds \quad (5)$$

where Σ denotes summation for the many masses (m, m^1, \dots). We write the integral (5) as

$$T - U = \text{constant} \quad (6)$$

As to the limitations of (6), we will state these in the next paper. The extension of (6), brought about as will be shown, is the principle of the conservation of energy.

PHILIP E. B. JOURDAIN.

PHOTOGRAPHERS ALL.—The hunting and shooting season has revealed the fact that amateur photography is now more extensively practised than ever. Almost every man and woman who visits a country house possesses a hand camera, which is sedulously manipulated throughout the day. Mr. B. Alfieri, of the Kodak Company, estimated recently that, although the photographic season proper is ended, hand cameras of all makes are at present being sold at the rate of half a million annually.—"The Echo."

A LARGELY attended meeting of the Isle of Wight Photographic Society was held in the Club Room, at Newport, last week, presided over by the president (Prof. J. Milne, F.R.S., F.G.S.), who commenced the proceedings by presenting the medals won at the recent exhibition, after which Mr. S. G. Kimber, hon. sec. of the Southampton Camera Club, gave a very able and interesting lecture on Winchester Cathedral, illustrated by 100 slides made from his own photographs. The slides were of a very high order, and the sunlight effects in some of them were very pleasing. The first meeting of the Ladies' Branch was held in the club room on Tuesday last, presided over by Mr. Leonard Jordan, T.C. Mrs. Twynham, of Cowes, was elected president, and Miss E. M. P. Bowles, hon. sec.

⁵ An account of which will be found in Mach, *op. cit.*, pp. 130-137.

FOREIGN NOTES AND NEWS.

MM. RIVIERE and Bailhache have presented a report to the Academie des Sciences, Paris, in which they state that they have found from 3-5 grammes of hydroquinone in a kilogramme of leaf buds of the pear tree, and that its extraction is easy. Notwithstanding this fact, we imagine that, chemically produced hydroquinone will not suffer a slump in price.

A good non-actinic paper medium can be made, according to Dr. Castellani, by the following method, and the result is a perfectly safe, but brilliant, orange red light, which is far pleasanter than the ordinary dark-room illumination. Paper should be soaked for five minutes in

Alcohol 95 per cent. 1,000 cc.

Auramine O. (Agfa) 5 g.

Alcoholic safranin solution (Merck 0.5 per cent.) 100 cc. and then hung up to dry.

M. Millochan has, according to the "Academie des Sciences," been photographing the spectrum of Jupiter, and has proved that there is an atmosphere which gives five absorption bands. The spectra were taken parallel to the line of the poles, parallel to the equator, and also at an angle of 45 degrees. The results obtained confirm the visual observations and general deductions of astronomers generally. The width of the slit was 0.075 millimetres, and using Lumières panchromatic plates, the exposure was 90 seconds.

In a recent number of "Lechner's Mittheilungen," Dr. Georg Hauberisser details his experiences in taking theatrical scenes during the performance, and recommends a lens of 12 cm. focus, working at about $f/5$, and a plate 9 by 12. The best place is said to be the front row of the balcony stalls, and the fastest ortho plates should be used, or ordinary ones colour sensitised by bathing. For brightly-lit outdoor scenes, three or four seconds is sufficient, whilst for interiors from 6-8 seconds suffices. An edinol developer was used, and the negatives intensified with uranium.

In the "Zeitschrift für Wissenschaftliche Photographie," Herr Braun details his experiments in the direction of finding to what extent oxygen acts in the formation of the latent image and he found that a much stronger latent image was formed in oxygen than in ordinary air. Plates exposed in nitrogen showed much less density on development than those exposed in ordinary air, from which it is argued that the greater the proportion of oxygen the more vigorous the latent image. In all probability the greater activity is due to the ionisation of the oxygen, and it is no proof that there would be no chemical action in an atmosphere entirely free from oxygen.

Drs. Riebensahn and Posseldt, of Berlin, have patented a modification of the carbon process, the essentials of which are as follows:—A gelatine-bromide emulsion is mixed with a pigment and coated on paper, which is then exposed, developed, and fixed, and washed as usual, the result being a silver image embedded in a gelatine film containing a pigment. The print is immersed in solution of potassium bichromate, and where the silver image lies the gelatine is tanned or hardened. The print is then washed and developed with warm water. One may have reasonable doubts as to the validity of this patent, for Howard Farmer, 1894, pointed out the principle of the process and showed before the R.P.S. the catalytic action of finely-divided silver in the presence of gelatine and bichromate. The advantages of the new process of which exact details are not yet forthcoming are that it combines the rapidity of the bromide process, with the ordinary carbon process.

M. Loeb, following on the lines laid down by Valenta, has

been experimenting with very small quantities of alkali added to an ordinary amidol developer, in order to form a monophenolate at the base, and has found that such a developer acts very rapidly and without fog, and is useful in cases of under-exposure. The formula given is:—

Water	1,000 cc.
Sodium sulphite (anhydrous)	3 g.
Amidol	5 g.
Solution of caustic soda, 1 per cent.	30 cc.

We believe that the first suggestion for the use of an alkali with amidol was made about ten years ago by the late A. R. Dresser, and certainly for some years Dr. Stolze has used such developer, the amidol being preserved in solution by a metabisulphite, and the acidity of this being neutralised by an alkali. Our experience is that the quantity of alkali must be very exact, or otherwise fog is invariably produced.

ON MR. STRAUSS'S PHOTOGRAPHIC "OLD MASTERS."

It was not so many years ago that the professional photographic communities of this country were somewhat startled by the daring originality of Mr. J. C. Strauss, of St. Louis, Missouri, in producing his "Lytrite" portraits; if I remember rightly they were first shown here by the Editor of this paper, and caused a great deal of wonder among the more conservative photographers. It will be recollected that they were a clever combination of drawing and photography, the two being most artistically blended so as to produce almost the impression of a wash drawing.

It need hardly be said that they were subjected to a storm of criticism, some of it, indeed, being of an altogether too personal character; and were, moreover, more or less imitated by several prominent workers on this side of the Atlantic. But Mr. Strauss is not a man to rest on his oars; he has recently branched out into quite a new line, and his latest productions, when they are seen over here, will, I imagine, create an upheaval of artistic impressions compared with which his former work was as a mere breath of wind on a cornfield.

In the October number of "The Photo Era" there are some striking examples of his latest departure, and Mr. Thomas Harrison Cummings contributes an eloquent defence of his unconventionality under the title, "New Photography after the Old Masters." I cannot do better than quote Mr. Cummings in his description of these new methods:—"His latest work in photography is the making of photographic portraits of living men and women after the old masters. These pictures resemble photographs of famous paintings, with the exception that the face is a perfect likeness of the sitter for the portrait. Taking only the best portrait painters for his guides and models of composition, he makes his sitter look in the finished picture like a Rembrandt, a Sir Joshua Reynolds, a Holbein, or a Dürer painting. It is the application of the inductive process to photography, the using particular facts to reach a general result. Given a good likeness of the subject as the first requisite he then constructs his portrait and secures his pictorial effects by copying accurately the composition and arrangements of accessories, the beauty of outline, division of space, contrast of light and shade, harmony of tone and colour from some painting of recognised worth by an old master."

Such, then, is Mr. Strauss's new style. One of the illustrations to the article is a portrait of Mr. Strauss himself after the well-known painting by Albrecht Dürer in the Prado Museum at Madrid.

Here we see a wonderfully exact copy of this celebrated picture; the coat is the same, so are the vest, collar, hat, and hair. Every detail of the painting is accurately reproduced in the photograph, only instead of the face being that of some unknown person, we have presented to us the familiar features of

the great photographer himself! The transformation is remarkable; it is quite one of the most interesting examples of quick change work I have ever seen; we no longer see Mr. Strauss as a mere modern American, but as an individual arrayed in the garb of four centuries ago, and possessing all the mannerisms of the period.

There are even more striking pictures reproduced in the same number of "The Photo Era," though, perhaps, the one of Mr. Henry Pierce, of Newport, who is depicted as a seventeenth century cavalier, after the picture by Franz Hals in the Vienna Gallery, will probably attract the most attention, as it is the most elaborate one; the method adopted, though, is the same in each case, and an exact reproduction of the selected painting is produced, with the exception that the face is that of the sitter to the photographer and not the one depicted by the artist. At first sight I must confess to a bewilderment of opinion as to the qualities of these productions; a variety of thoughts chased through my mind. At one moment I admired them, but at the next a revolt sprang up at what seemed to be a desecration of the world's accepted art masterpieces. We have, indeed, come to regard the pictures which have been collected together in the numerous galleries at home and abroad with a feeling akin to reverence; and the more we get to know them, the more we study them, the more we analyse their technical and æsthetic qualities, so must we, unconsciously, if we may, place them in the position of objects of veneration in the shrine of our hearts.

It seems to me not to be possible, if we desire to act fairly, to take a one-sided view of Mr. Strauss's latest productions. As soon as we criticise them from a mere party standpoint, it is only with the greatest difficulty that we can prevent a spirit of bitterness entering into our judgment; we might persuade ourselves that such work was a gross act of vandalism, and thereby be doing a great injustice to Mr. Strauss. On the other hand by a solid defence of them we are liable to take them too seriously and to give them more credit than they are really entitled to. It is, admittedly, an original idea to block out the faces of old-time portraits and in their place to insert those of modern men and women, and it is capable of being judged as an act of homage to those past masters of the painter's art, as a slur upon present-day methods, or as evidence of the gratification of the vanity of modern individuals.

Perhaps the latter point of view is the safest to take, although on the other hand it is the most dangerous, as the ideas now started may be so extended that no picture will be safe from the hand of the photographic copyist, and ridicule will be reflected by the uncultured on the honoured treasures of different nations.

I do not think, though, that we should take Mr. Strauss too seriously; in fact, by regarding them in the light of theatrical productions we at once disarm ourselves of all weapons of hostility, and can quietly sit down to enjoy them as we would a fine setting of one of Shakespeare's dramas at His Majesty's Theatre.

The idea is one which would not unnaturally occur to an American, but it is hardly one which will find favour in the eyes of our more insular conservatism. America is a land where nearly everything is done on an ultra up-to-date scale, and where the time-honoured traditions of the past are not so capable of exerting their influence on the everyday life of cultured society as they are over here. It is not to be wondered at that Mr. Strauss, on a first intimate acquaintanceship with the old masters should have found himself transported into a heaven of delight at their artistic greatness; nor, indeed, that, in the excess of his enthusiasm, he should have instinctively drawn a comparison between modern photographic portraiture and that practised by those great men of the past.

But there, I think, Mr. Strauss should have stopped, for, in copying them to such an extent as he has done, I cannot help

feeling that he has laid himself open to be seriously misunderstood.

There is another side of the question which has, perhaps, not suggested itself to Mr. Strauss's mind; I refer to the more personal one of the sitter's individuality and status in life. In America, I believe, every man is, socially, the equal of his brother, but this is not, fortunately, the accepted doctrine in the British Isles; in fact, we regard the privacy of the individual as a matter permitting of no public intrusion. As long as Mr. Strauss chooses for his copies portraits whose sitters were unidentified, as he has done in his own case, there seems to be no grounds for objection on this score; but once let this rule be broken and unintended insults to possibly still surviving families seems to follow as a matter of course. Somehow or other the portraits of the old masters must always be associated in the mind of a cultured person with the personality of the sitter, and not merely as a surpassingly beautiful work of art, and therefore any outrage on these works is not only committed against the artist, but also against the individual represented in the picture.

In this connection I cannot help feeling that it would be evidence of very bad taste to take, for example, the son of some candy store proprietor, dress him up and make a photographic copy of the painting of Philip, fourth Baron Wharton, by Sir Anthony Van Dyck, now in the Hermitage Gallery, St. Petersburg; or some woman of ordinary bloodstock to impersonate Mrs. Hart, after the painting by Sir Henry Raeburn in Major Northcote's collection; it is carrying the thing too far. Why! we might perhaps be inflicted with a picture of the daughter of a pork millionaire with her offspring, posing as the Duchess of Devonshire and her baby after the celebrated picture by Sir Joshua Reynolds in the noble Duke's collection!

A. V. KENAH.

SOME NOTES ON ACETYLENE.

The first introduction of acetylene was welcomed by photographers generally, and particularly by amateurs, because it was thought that here was the ideal illuminant for lantern work, enlarging and reducing, and photomicrographic work, but somehow it does not seem to have quite fulfilled expectations. Why, one is not able to say offhand. My personal experience with it has been most happy, but then I have only used it for lighting two rooms in my house, that is miles away from any gas report.

A few facts, however, as to acetylene generally may not be out of place. In the first place everyone knows, I suppose, that it is produced by the action of water on calcium carbide according to the equation:

Some trouble has been caused by possibilities of explosion, from mixtures of acetylene and air, but, speaking after two seasons' trial of it, I may say that although a great smoker, and a constant smoker, I have never yet been unable to detect the presence of free acetylene in a room—its stink is characteristic; and then, again, there is a lot of misconception on this point. If there is one volume of acetylene to five parts of air, the explosion is most violent; above and below this proportion the danger of explosion diminishes, but any one who cannot detect even one in forty by his nose must be at least wanting in one sense.

If any one is wanting not in the sense of smell but in commonsense, and goes to seek for the leak with a light, as some people do even in the case of ordinary gas, then of course there is likely to be trouble, but this is not the fault of the acetylene. Explosions when filling or emptying a generator are generally caused by carelessness in doing this at night by a naked

light. I have been told that there is likely to be trouble if the light is applied to the burner before the whole of the air is driven out of the generator. I have lit my burner many a time when there certainly has not been pure acetylene issuing, but only now and then do I get a pop, and the tap can be instantly turned off and the light put out and more gas allowed to run through.

I had some little trouble at first with the sludge left in the generator, some would stick and stink, and it was a nuisance, but since I adopted the system—whose idea it was I do not know—of putting a fair amount of common brown sugar in the water I have had less sludge and a more even generation of acetylene. The action of the sugar is to form saccharate of lime, a soluble salt, and I have found this liquid, when diluted, a capital manure for my garden. The more even evolution of acetylene is of course due to the sugar forming what one might call a physical restrainer to the action of the water on the carbide.

Some scare was raised a little time back that acetylene was more poisonous than ordinary gas, but that, from experiments on animals, other than man, has been proved to be wrong. Anyway, a cat can stand a mixture of air with 9 per cent. of acetylene when an equivalent mixture of coal gas promptly poisoned the poor brute. Acetylene, too, gives just about half the amount of carbonic acid in burning that coal gas does, and there is practically no formation of the deadly carbon monoxide as is always the case with coal gas.

I do not know who the authority is, but someone has proved that acetylene is 47 per cent. cheaper than the electric light and 34 per cent. cheaper than the best paraffin, and about 40 per cent. dearer than the incandescent gas light. Anyway, my experience is that the room is cleaner and cooler with acetylene, and that one can see colours much better, and it is exceptionally useful for contact printing on bromide or gaslight papers, on account of its richness in blue and violet light.

F. BRETT.

SOME AMERICAN PICTORIALISTS AND THEIR WORK.

In the face of the somewhat conflicting statements as to the proposed exhibition of the Salon Club and the Annual American Salon, which is to be held next month in New York, the following article from the pen of Sadikichi Hartmann (which appears in the current issue of the "Journal of the Photo Society of India"), the art critic of New York, will be read with interest:—

In studying pictorial photography, it becomes evident that the most individual work has been more often than not the outcome of a well defined movement. Sometimes a single worker instructed the whole school, at others a few working in familiar intercourse acted and re-acted on each other, so that at last a distinct character was imparted to their work.

New York at present shelters the headquarters of two such groups, the Photo-Secession, under the directorship of Alfred Stieglitz, who has long held the premier position among American pictorial workers, and the Salon Club, organised by Carl Rau and Louis Fleckenstein, an association made up largely of energetic workers of the younger generation.

Although separated from each other and outside workers by the boundaries of their cliques, the aim of both societies is very much the same. The Photo-Secessionists endeavour to compel the recognition of pictorial photography "not as a handmaiden of art but as a distinctive medium of individual expression"; while the object of the Salon Club workers is to encourage "photography that gives distinct evidence of artistic feeling in subject and execution."

But the way and manner in which the two groups carry out their plans is totally dissimilar. The Photo-Secession, in whose ranks we find such well-known workers as Gertrude Kasebier, Frank Eugene, C. H. White, of Newark, Ohio, Alvin Langdon Coburn, W. F. James, of Chicago, etc., is a very exclusive organisation. Although limited to a certain style of work, their artistic standard is a very high one. They are all tonalists who favour the mysterious and bizarre. They like to suppress all outlines and details and lose them in delicate

shadows, so that the meaning and intention of their prints becomes hard to discover. They not only make use of every appliance and process known to the photographer's art, but without the slightest hesitation overstep all legitimate boundaries, and deliberately mix up photography with the technical devices of printing and the graphic arts.

The members of the Photo-Secession only exhibit lean collections and only accept such imitations as leave them a free hand in the selection of their exhibits; they insist moreover that these collections be hung together as an entirety. This sounds rather dictatorial in a democratic country like ours, but their scheme has nevertheless met with considerable success. They have held exhibitions in camera clubs and art institutes throughout the United States, and at this very moment are represented in five European exhibitions at Paris, Vienna, Dresden, Bradford (England), Haarlem (Holland).

The Salon Club works on a far more liberal basis. True to its motto: "Many Schools in Art and All Good," it tries to give everybody a chance. Their first exhibition, the Annual American Salon, will be held in December at the Clausen Art Gallery, New York. The co-operation of all artistic photographers in America and throughout the world is insisted, and it is hoped that also some of the foremost camera workers of India will respond to their cordial invitation. An exhibition of the highest order is expected, as it is the first exhibition of national scope under the control of a committee from all sections of the United States.

In the prospectus we are furthermore informed that "there will be no favours to any and no discrimination against any. All work, whether from the famous or the comparatively unknown artist, will be exhibited equally, and the jury will not know the names of contributors until after the selection has been made. No one 'school' or 'fad' will command precedence. The standard of judging will be the artistic quality of each print submitted. The jury is composed wholly of artists by profession—those who give their time and effort entirely to matters of art, and all of whom are experienced members of the jury at one or another of the American Academies."

(Copies of the announcement can be obtained by writing to the chairman of the Salon Committee, Mr. Curtis Bell, care of Lotos Club, New York City.)

The Salon Club consists at present of twenty-one active members, residing throughout the country east of the Mississippi River. The peculiarity of this club is that each member is a serious worker who has taken up photography not merely as a pastime but as a strenuous life study, and that each is so far technically and artistically advanced as to represent a distinct individuality. There are no lay members as in the Photo-Secession, with its membership list of over sixty names, of which less than one half, however, are actually engaged in pictorialism.

To get an idea of the importance of the Salon Club movement, it is necessary to mention at least the names of some of its most suitable workers. New York is represented by Zaida Ben Yusuf, the portraitist; Rudolf Eickemeyer, the most popular pictorialist in America; and Curtis Bell, the hardest worker of the Salon Club and the organiser of the exhibition; Philadelphia by Walter Zimmerman and Adolphe Petzold, an accomplished gum worker; Baltimore by Mrs. Jeanne E. Bennett, known by her depictions of the women and children of Holland and Brittany. Then there are W. G. Gosthell, of Walleston Hall; Louis Fleckenstein, of Fasibault, Minnesota, a very eccentric and promising talent; Henry Hall, a depicter of children *par excellence*; Carl Rau, of La Crosse, Wisconsin, who tries himself in symbolic genre; J. H. Field, of Berlin, Wis., one of our ablest landscape photographers, and the Parish Sisters of St. Louis, who despite their youth have already performed some excellent work.

The tendency of the Salon Club Workers is on the whole more and more normal than that of the Photo-Secessionists. They excel in landscape, popular genre and the depiction of child life, subjects which are rather tabooed by their elder colleagues. Their practice of technical devices is, however, equally open to criticism.

There is hardly a pictorialist nowadays who does not practise the trickeries of elimination, generalisation, accentuation or augmentation. They all wish their prints to look like etchings, monochromes, wash-drawings or the reproductions of paintings.

It may be interesting to investigate how this change in our photographic taste evolved. At the start it was merely the outcome of a

revolt from the conventional photographic rendering of sharp details and harsh contrasts.

This was refreshing, as the old-fashioned work had but little claim to beauty. Steiglitz, Eickemeyer, Dumont at that time, in the early nineties, did some remarkable work. Then some new technical methods were introduced which completely revolutionised photographic work. The first was the gum process introduced by Robert Demachy and carried to its utmost possible limit by several American workers; the second was the glycerine process as practised by J. T. Keiley, and the third the manipulation of the plate, the so-called process of photo-etching introduced by Frank Eugene. It is difficult to state which of the three processes has done the most mischief. In the meanwhile Alfred Steiglitz, who has become the champion of artistic photography in America, continually clamoured for more "individual expression." And, as individual expression in straight photography is extremely difficult to attain, the pictorial photographers begin to imitate the artist. Individual opinion became synonymous with "painter-like expression," and as the three processes mentioned facilitated their efforts in that direction, they were adopted by all the camera workers of the new movement. And in the highest aim of artistic photography really consists of successfully imitating the pictorial qualities of other arts, they can claim to have reached perfection.

But nearly all critics agree that the ideal of photography lies in an entirely different direction. Photography should be the record of our life and time. And if the pictorialists fall short in that, they merely show that their art is still in an embryonic state. Imitation is nothing but a step towards art, and the present accomplishment of an American pictorialist therefore merely furnish the proof that the technique of the photographer is pliable enough to produce something at once novel and, in its own way, beautiful.

"WHAT IS ART?"

On this subject Mr. R. Catterson Smith, Head Master of the Birmingham School of Art, recently gave a lecture to the members of the Birmingham Photographic Society. The lecture was based on Leo Tolstoy's recent book with the same title, and was an exposition of some of the writer's definitions of art and of the ideals it should keep in view. The question, the lecturer remarked, was no new one, yet it seemed strange that after all that had been said and written on the subject, after the life work of great teachers like Ruskin and Morris we should still be calling out, "What is art?" The fact is that art is so much a matter of personal feeling that it is extremely hard to give a definition which will suit us all and at all times. What satisfies to-day we cast away to-morrow. That this should be so shows how little grasp the majority have of the subject. It was Morris who said that we talk about art because we do not know anything of it. If we "felt" it as an inspiration, made it an act of worship, so to speak, we should know by instinct what was art. This was the spirit of the Middle Ages—before the revival of learning—that time when those glorious tributes to the spirit of religion—the cathedrals were being built, and the art galleries of the world being enriched by some of their choicest treasures. Then art was a serious business, it was a reality, bound up with the daily worship of God. These old painters and sculptors put their whole soul into the visions which they tried to work out on canvas or stone; they were as real as a dream often is to us. But in time, with the greater spread of learning, there came an increase of ease and of luxury, with increased wealth, and this brought a serious degradation in the ideals of art, which has gone on through the centuries, the bad oftentimes almost choking the channels through which good art was trying to spread its quickening impulse. And so to-day we have an art in which the lower influences seem to be uppermost. Art has lost its seriousness and become an affair of pleasure and amusement, of the drawing-room rather than of the sanctuary. It is well, therefore that some prophet should now and then point the way to better things. Such a prophet is Tolstoy; strenuous in all he undertakes, he is not the least so in his championship of a noble ideal in art. He draws a distinction between two classes of pictures, those painted solely with an idea of pleasure of beauty, and those which bore a definite message, which had in them lessons drawn from the heart of the painter. The lecturer gave illustrations from modern paintings, and placed in forcible contrast

"The Emigrants," by Madox Brown, and "The Dreamers," by Albert Moore; the former charged with grim reality in every line, the latter reveling in pure luxuriousness and pleasure. The contention of Tolstoy is that those pictures which are painted solely to give pleasure are bad; the aim of the artist should be to give some expression of his individuality, some fragment of his experience for a lesson to others. Let us get back to the ideals of the old-time painters, and let us have a vision and seek to express it the best we can. In a word, it is not colours only we must put on the canvas but a little bit of ourselves, and if we can do this there is no need to trouble about perfection in workmanship, for we have achieved something far greater than this can ever be. All this is not meant to imply that an artist may not have pleasure in his work. Tolstoy himself would say that the more the artist gave expression to his feeling the more pleasure he would have in his work. This then is his first ideal of art—seriousness. Closely connected is truthfulness. All art is in need of this virtue, both in conception and execution. To each subject there must be its proper treatment, or a jarring discord is produced, where harmony was intended. To tell a lie on canvas is as bad as to utter it with the lips. First, we must have convictions and then be true to them. Third, art should have simplicity. There seems in many quarters an idea that only great themes should be attempted, if one wishes to achieve anything in the world of art. No greater mistake could be made, for it will always be found that the simpler the subject the wider is its application. The most universal subjects are those which by their simplicity can reach the greatest number, the heroic finds a much more limited auditory. Again, we must not be imitators or copyists of another's work; too much of present day art is borrowed, sometimes whole themes being thus pilfered and dressed up to appear as new. True art has to pass the test of originality. Perhaps greater than all it must be closely bound-up with morals. There is no divorce between art and morals, as those seem to believe who talk of art for art's sake. There is a saying of Goethe's that he who would paint for princes must live like a prince. Now, as princes have not always been remarkable for the virtue of their lives, this is equal to saying that in art morals do not count, a suggestion which Tolstoy repudiates. All that has been said applies, of course, to any expression of feeling, of which photography is but one mode. Surely here also we can apply Tolstoy's rules. We can seek to be serious, to work with a higher aim than merely pleasure. We can try to be something better than mere "recorders." We can be simple, not striving beyond the obvious limitation of our craft. We can be universal, owning no school or cult as our master, seeing that all methods are but differing means to the same end.

THE FUN OF VELOX PRINTING.

(From the "Velox Manual.")

The fun was not on my side. Oh, dear, no; it was the other way about. I got laughed at, but I am not the first parent whose children have made him feel small. It happened in this way. A sample Velox Printing Outfit came one day from Messrs. J. J. Griffin and Sons with a polite request that I should try it and report. This outfit lay on my table a long time—over a year, to be precise—and might have been there yet if one of my children had not come into the studio one day when sitters were scarce. "What," she exclaimed, "have you begun to use Velox?" I thought you only did your printing in carbon and platinum." I explained that this was only a sample, but that I would show her how it was worked if she liked to stay.

We took the box into the room where the frames are filled, pulled down the yellow blind, and lit the gas. While opening the box and mixing the developer I said to my little girl that most of these new-fangled printing papers professed to save a great deal of time, but that really they did nothing of the kind, and that the prints they gave were not worth looking at. Then I picked out a good strong negative and opened the packet of paper, which was marked "carbon." Keeping away from the gas, I "filled in" the frame, and exposed the paper and negative to the flame at a distance of five inches for sixty seconds, and, returning into the corner of the room again, I began to develop; at least, I mopped some developer over the paper with cotton wool for a minute or two, but no sign of any

image appeared. Eventually a ghost-like picture did come. "This paper is evidently very much slower than they make it out to be," I said. "Or maybe you were in too big a hurry, you dear old fidget," was the reply. Then I pointed to the instructions, where it said the image would appear suddenly, and asked her if she called five minutes sudden. A second exposure of two minutes brought up the image quicker, but one so black and so white that it was thrown into the waste-paper basket after its first brother. Four more attempts were all equally bad, for after the second I had mixed a developer which I thought would give softer images and more half-tone, but which only fogged the image entirely. "Come and have some tea now; if you have twopence I will go buy buns," said my little girl. Then she added, "After tea I will show you how to use this paper." I smiled an incredulous smile, for I knew she had never made a print of any kind, not even a silver print. The tea was an unusually quiet one, for the little girl devoured the Velox instructions as she ate her buns and drank her tea.

"When you are quite ready we will go and make some beautiful Velox prints," woke me from my reverie.

"We will not try to make any more from that negative," said my little girl; "it is too hard and much too yellow. We will try tins one of the ducks."

"That!" I exclaimed. "That won't print; it is much too thin."

"Hush. Seventeen, eighteen, nineteen, twenty. Done. Now come and watch me develop it. Is this the developer that came with the paper which you mixed first?"

"Yes."

"You are quite sure you threw that last lot you made out of your own head away?"

"Yes."

"Then look here."

Deftly slipping the print into a dish of water for ten seconds, she then emptied the water out and poured on an ounce of developer; at once the image appeared. And in a few seconds she poured the developer off and rinsed the print with water, and put it to fix. Seven other negatives did she pick out, all of which I had put on a shelf to be intensified and made fit for printing some day. From each of these came a print, strong in the dark parts, pure in the high-lights, with abundant half-tone.

"There, you dear old fossil, what do you say to these? Are they worth a penny each?" So I had to give her eightpence. "You stay here, I'll be back in a minute." In a few minutes she came running upstairs with another packet of Velox in her hand. "Where is that dense yellow negative you tried at first?" she asked.

I pointed to it.

"How long did you give that first print which was so pale?" she inquired.

"Sixty seconds," I answered.

Then, putting a new piece of paper in the frame beside the yellow negative, she exposed it for the same time.

"Come along and see some more magic." I went and saw, I am ashamed to confess it, a fine, soft print develop up quickly, suddenly I should say, in my child's hands. Reader, if you have never felt small you belong to that class I have no wish to talk to. If you have, you will sympathise with me. Did not I get laughed at?

"Now, you dear old dad, when your printers go on strike whistle for me, and I will do your prints all on Velox in less than a quarter of the time they do them in, and as for wages, let me see, I'll come for sixpence a day; and I want a new hat, and I should like a blouse, too. I am quite old enough to wear one, don't you think so?"

FRANK M. SUTCLIFFE.

P.S.—I learnt afterwards that the second packet of Velox was of a different make from the first. It was labelled "Portrait." The baby had bought it with the eightpence at the chemist's opposite.

THE Grand Prix at the St. Louis International Exhibition has been awarded to the well-known photographic optician, Mr. C. P. Goerz, of London, Berlin, Paris, and New York, for excellence of manufacture. The exhibit of the firm comprised their photographic lenses, cameras, and the Trieder Binoculars; and they also constructed the apparatus used for the projection of Dr. Miethe's three-colour photographs.

ON PICTORIAL PROTECTIONISM.

ONCE exclusiveness gets a hold in a society or association, it seems to flourish upon itself until a time arrives when the exclusive dwindle down to one individual, who, unwilling to exclude himself, suffers his own presence. Have we not the classic instance of the Scotch minister who doubted the saving grace of all his flock excepting one, and even of him he had his doubt?

These reflections arise out of the Photographic Salon; one exhibition controlled by a brotherhood which, originally founded to merely exclude the show-case and its smooth-faced abominations, has since been steadily squeezing out all whose photography is too light, or too sharp, or too "literal" to please the standard of the Linked Ring. Names might easily be mentioned, but had better not.

At the moment of writing some of the outcasts are roaring and ranting at a fine rate, and amongst them are men whose reputations stand very high in general esteem. This, however, is no recommendation to the inner ring, for anything which is popular is, *per se*, cheap; only that which is beyond the comprehension of the multitude is profoundly clever pictorialism. Thus it is that all England cannot supply the Salon with more than about 100 prints, which will pass muster. Even so, it is an open secret that some of the "uncogude" would, if they could, have excluded many of those which have found a place on the walls.

If the rumours I hear are true, a time is at hand when the exhibition will be run by something in the nature of a council of three, which, I suppose, will ultimately come to a dictator and two secretaries. Should he chance to be, say, a platinotypist, woebefitting any hapless gumists who should send travesties of photography or any "artists in boiled bromide" who should dare to offer their prints for hanging alongside of Mr. Steichen's dainty deeds of darkness. Of course, societies devoted to the encouragement of art cannot in the abstract have too high an ideal, but in practice it often means a gradual narrowing, not broadening, of aims; as the Royal Academy found by its virtual exclusion of Burne-Jones, Albert Moore, Whistler, and the rest. Young artists—or let us say pictorialists—are many of them exceedingly nervous and diffident. They shrink from a rude rebuff, which they not unreasonably might consider the rejection of all their prints to be. Those who have been through the mill take their exclusion less tragically. A talented man not long since tried his fortune at a certain exhibition with a score of his best works, every one of which "came back." Did he grieve? Not much. Perhaps he put it down to a personal objection the society had to him. Maybe he deplored that they should be so crassly ignorant as to be blind to his examples of the coming pictorialism. Who knows? Anyhow, he smiles. But the pale, young enthusiast, terribly earnest neophyte, who cannot sleep o' nights for wondering how his prints will look, and what the people will say when his pictures hang at the Salon, is completely knocked out of time when the ruthlessly exclusives give his gems "the chuck."

Some of this species never get over it; others boycott the Salon for eternity. A clever young man who was too impressionable, to whom befell the unpleasantness of getting back five important, or at least he considered them so, "nocturnes" and "symphonies" was only saved from throwing up the sponge by a broker. His frame bill came to over £2, what his prints cost it is impossible to compute; anyhow, determined to make an immediate end of his photography and shut it out of his memory, he called in a dealer in second-hand goods. On looking them over, the man considered that his prints were absolutely valueless, he however offered 3s. for the frames and glass! The shock steadied the neophyte; he dismissed the art-less dealer, and kept his photographs by him to be used as occasion arose for birthday presents. Not long after a painter of considerable ability, chancing to see them, fell into ecstasies with one, which was, however, the worst of the five; moreover, a knowing friend pointed out that if the broker and the hanging committee were of one mind the latter must have been a very poor lot. And so the young man took fresh heart, tried his fortune with the five at an important provincial exhibition; got a second-class medal, and so started on a moderately successful career, which was almost nipped in the bud by photographic protectionism.

It is true that to this day I myself do not think much of his form, and so he would have been no great loss, but I think just as little of not a few of those who are regularly hung on the line at the big exhibitions. I daresay my opinion is not unshared by others, but it would be hardly polite to give such thoughts words when, at the

very least, an expression of praise couched in non-committal platitude is expected by all concerned.

Not long since, being with some photographic critics at an exhibition, three of us came to a picture which was a regular "eye opener."

"Who is it by?" asked one of them.

"By the late Park-Blank," said I, reading from the catalogue.

"Then, thank goodness, I am not obliged to notice it."

This fancied obligation to notice everyone's works is carried out to the extreme by some of the photographic journals, which in the case of the "Salon," undertakes to butter or slate everything on the walls. The main effect of which is to feed the vanity of the weaker vessels, who are encouraged to go on perpetrating prints which are possibly hung on sufferance, or as foils to other photographs. The encouragement of the incapable is one of the serious troubles which stands in the path of pictorial progress. Men of small parts, but of huge patience and determination, peg away at picture-making and grope for masterpieces. A certain kind of photography notably a lottery, tempered by selection of subject, trimming print, and diligence in technical practice. The Homunculus habitually pecksniffing subjects and their treatment; constantly taking "counsel's opinion" upon his prints; continually waiting to "assess" late someone's "happy thoughts." And so, some day, having been medalled at the "Royal" and discovered by the technicals, "arrives." From which time forth he becomes an insufferable nuisance; a man who can brook not one word of truth; who finds even honied praise insufficient, nothing less sweetly intoxicating will serve than a long adulatory drink of chartreuse.

None the less we put up with him; that is to say, so long as he is moderate in his abilities. So long as he makes no overdraft on our intelligence we are content to humour Mr. Small Part. He is, to speak, one of us; a lucky dog who, after all, has only done what we ourselves are capable of rivaling, if not excelling. But once Mr. Small Part belie his name; once let him try and humbug with his newfangled and obscure experiments, then with one voice we denounce him as ignorant or a charlatan. Whatever we do not know or cannot see or do not enjoy, is wrong, base, and must be stamped out. Those who hold such opinions may be numbered by the hundred. They flourish on their lack of knowledge, of sympathy and of innate capacity. Show them pictorial something to which they are unaccustomed and they will not be able to tell you whether they are pictorial sublimities or artistic jokes.

There are, of course, some few people who really are judges, people who will freely give an opinion and a reason for it without waiting to hear the opinion of the crowd, or fearing to express unambiguous terms what they actually think. These are the people who ought to write critiques, but who, as a rule, do not do so. Perhaps they would damage the circulation of the average publication or create a little shindy amongst the societies. Of such was amateur who, a few days ago, exclaimed in a fury of indignation at certain prints which had found a place at the "Photographic Salon"—"Had I known these would have passed the hanging committee, I would have travelled a thousand miles to prevent such a degradation of the display."

This is the kind of whole-hearted, hard-headed, outspoken, "know what I am talking about" kind of person whose influence is to be kept out pictorial imposters, and let in those who dare to affront the mediocrities with innovations and refinements which are, sometimes, as caviare to the multitude.

Let me not be misunderstood, not everything that is good is appreciated or jeered at. Some things which reach the heights of pictorial empyrean are acclaimed by the multitude. This is, however, generally an accident. The photograph is not admired for its artistic superabundance, but for some secondary feature which it happens to possess, and which the ordinary crowd is captivated by. Take the Salon, for instance, what there is in it that is strenuous and lofty conception, the pictures which have, by dint of huge efforts, pushed on the course of photography in the direction of its recognition, a branch of pictorial expression worthy to be placed in the company of mezzo-tint or etching, have been but coldly received. The people have been told that they are phenomenal, and have, with due obedience, mildly admired them, much as the gallery boys of the Galerie might listen to the "Dream of Gerontius." But the real sympathy and appreciation of the visitors who have thronged the Salon are bestowed on "Currants" and "Cats"! The former is a splendid

example of the F64 photograph, such as may be met with in florists' catalogues, and is twice as natural as nature. The second, well, it is an excellent photographic photograph of two kittens. Both these exhibits have their frames studded with red wafers, signifying that copies have been ordered. Let there be no mistake, other prints, some of which deserve every distinction they are likely to receive, have found buyers; but that there should be such a rush upon cats and currants, and similar productions, and that, moreover, the elect of the select should have hung this type of photograph in a collection purposely designed to show that Art can glorify Photography, baffles the mind."

If in the beginning of these rapidly-penned reflections I seem to object to exclusiveness, it was not the exclusiveness which is born of narrow views or jealous dispositions, but the exclusiveness which would keep out anything banal, trite, poor, or puny; which would, without fear or favour, turn every single print which did not bear on its face a signification that its claim to enter was that it was a child of Art, is to be hoped for, if not expected. Having written so much, let me add that I do not consider all exhibitions should be run on such a line. There are minor poets who sing very sweetly, and there are also minor photographic artists who turn out splendid "dying swans," sweet "kissy-mummy" children, accurate copies of picturesque buildings, and so forth. These productions give the greatest delight to thousands of people, and exercise a most elevating influence upon the amateurs who produce them; indeed, in some cases, they may be considered "stepping-stones to higher things."

Besides which, photographic technique is a thing which requires looking after; for what the technician or craftsman finds out to-day to-morrow in the hands of an artist produce a graphic miracle. For which, and a good many other reasons, let us have not only "secessional," but also plenty of ordinary exhibitions where we may all learn to walk before we attempt to run.—"Journal Phot. India."

HECTOR MACLEAN, F.R.P.S.

Exhibitions.

SHEFFIELD AND HALLAMSHIRE SOCIETY'S EXHIBITION.

Last week the third annual exhibition was opened, in the Lecture Hall, Cemetery Road Baptist Chapel. The exhibits of work done by the members numbered about 250, a decrease as compared with last year's show, but this was compensated for by the superior quality. The members are aiming at effect, and the result is that some artistic photographs, worthy of professional skill, are on view. Discarding the old-fashioned silver and P.O.P. prints, the ambitious amateurs are resorting to matt-surface and carbon. Mr. C. D. Rose has obtained the society's bronze medal offered for the best print taken on the Saturday afternoon excursions. It is a very pretty landscape, artistically composed. The bronze medal offered by Mr. G. H. Bagshaw, for the best set of three prints taken on the annual excursion, which this year was to Worksop, has been awarded to Mr. C. H. Tomlinson, for two views of Worksop Priory Church and one of the ruins of the Priory Chapel. They are very creditable works. A prize is also given to the member who wins the most certificates in the monthly progressive competitions. The subjects during the session have been:—a study of a portrait, pictorial postcards, mounted print, cloud studies, landscape, woodland scenery, architecture (interior), general study, portrait by flashlight. In these subjects the members have distinguished themselves, and the prize for the possessor of the most certificates has also gone to Mr. C. H. Tomlinson. His cloud study is particularly creditable production. A silver medal is given by the president for the best print in the exhibition, but the award has not yet been made. Mr. S. Taylor has some beautiful photographs of the interior of Ely Cathedral. An interesting series of photographs taken by the president (Mr. F. Mottershaw), showing the daily work of the Sheffield Fire Brigade, is on view. The pictures are wonderfully clear, and are in every way excellent.

HUNTINGDON AND DISTRICT AMATEUR PHOTOGRAPHIC SOCIETY.

The second annual exhibition in connection with the Huntingdon and District Amateur Photographic Society, which was formed in 1902 with the object of encouraging the art of photography among its

members, was held on Wednesday last week at the Volunteer Headquarters, Huntingdon, by kind permission of Colonel Linton. In point of size the exhibition was about the same as that of last year, but the amateur work sent in for competition showed considerable improvement, all classes being remarkably good. There was also a fine collection of photographs and other pictures not for competition, lent by members and friends of the society, and the work of the members done for the monthly "portfolio" also created a good deal of interest. There was a large attendance of visitors during the afternoon and evening. We append the prize list:—

Class 1.—Architectural Subjects: 1, Mr. E. Trench Smith; 2, Mr. H. Goggs; c., Mr. H. Dawson.

Class 2.—Landscape or Seascape: 1, Mr. H. Goggs; 2, Mr. E. Trench Smith; h.c., Rev. G. R. Holt Shafto.

Class 3.—Instantaneous Photos: 1, Mr. E. Trench Smith; 2, Rev. G. R. Holt Shafto; v.h.c., Mr. Dalgleish; c. Mr. H. Goggs.

Class 4.—Portraiture or Figure Study: 1, Rev. G. R. Holt Shafto; 2, Mr. E. Trench Smith.

Class 5.—Lantern Slides: 1, Mr. H. Goggs; 2, Mr. H. Dawson; h.c., Mr. J. W. Tysoe.

Mr. W. C. Bernard offered as a prize a "Gilvus" and "Absolutus" Light Filter for the best photograph of a "Sky and Water," and the Rev. G. R. Holt Shafto was adjudged the winner.

SUNDERLAND CAMERA CLUB.

The following were the awards of the judges, the Rev. F. C. Lambert and F. M. Sutcliffe, at this exhibition held last week:—

Class I.—Landscape or Seascape: Silver plaque, "Borderland," Arthur Payne, Gateshead; bronze plaque, "A Misty Morn," W. Clayden, Plymouth.

Class II.—Portraiture and Figure Study: Silver plaque, "As He Sowed," E. T. Robson, West Cramlington; bronze plaque, "The Gum Splodger," Miss A. B. Warburg, London.

Class III.—Members: Silver plaque, "A Manx Glen," R. Chalmers, Sunderland; bronze plaque, "Study in Pose," B. Jackson, Sunderland.

Class IV.—Societies in Northumberland and Durham: Silver plaque, "Durham," F. Harrison, Fulwell; bronze plaque, "Evening in the Woods," N. Bradwell, Sunderland.

Class V.—Lantern Slides: Silver plaque, "An October Morning," W. A. Clark, Birmingham; bronze plaque, "In the North Choir Aisle, Ely," H. Wormleighton, Leicester.

Class VI.—Architecture, etc.: Silver plaque, "Chillion! Thy prison is a holy place, And thy sad floor an altar," P. W. Crane, Heanor; bronze plaque, "Notre Dame," Caudebec, W. S. Corder, North Shields.

FORTHCOMING EXHIBITIONS.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

November 25-26.—Ilford and District Photographic Society. Hon. Sec., W. N. Beal, 155, Thorold Road, Ilford.

November 26-December 3.—Glasgow Eastern Amateur Photographic Association. Secretaries, John Brough, 68, Dalmarnock Street, Park Head, Glasgow; and Geo. R. Johnstone, 591, Alexandra Parade, Dennistoun, Glasgow.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 23-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 133, Glasgow Road, Wishaw.

January 12-14, 1905. Boston Camera Club. Hon. Sec., H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 25-March 4, 1905.—Birmingham Photographic Society. Hon. Sec., Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14, 1905.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Sec. John B. Parnham.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

New Books.

"The Ancient City of Canterbury." Published by the Canterbury Chamber of Trade, and Cross and Jackman, Canterbury.

This work has been published with a view of making generally known and inducing travellers to visit "Canterburie, the head citie of all that countrie." The literary matter, which is extremely interesting, was written by Dean Farrar, Canon Routledge, Sebastian Evans, and Francis Bennett-Goldney, hon. directors of the Royal Museum, and these names are at once guarantees of the correctness of the information given. The work, which is handsomely bound, is unusually rich in half-tone illustrations.

"Inks, their Composition and Manufacture." By C. Ainsworth Mitchell and T. C. Hepworth. Published by Chas. Griffin and Co., Ltd., Exeter Street, Strand. Price 7s. 6d.

The value of this work to all those interested in the subject will, we think, be at once admitted on perusal, but to the photographer it possesses but a minor importance, except as regards the section on three-colour printing, which, however, is singularly incomplete. Again, we would like to point out a complete omission of Professor Valenta's invaluable researches on the stability of aniline dyes in the form of printing inks, and of Haruza and Hruza method of making the same, and some notable papers on this subject by the head of the Vienna State printing works.

We are not sufficiently masters of the subject to speak as to the general information contained in this book, but it shows evidences of careful research and work, and is rendered all the more useful to the technical ink-maker by the inclusion of a complete list of English patents. It is somewhat curious to find the authors stating in their preface they are indebted to an artist "for the excellent drawings of the various galls, the details of which could not have been nearly so well shown by photography."

New Materials.

Seltóna and Leto Gaslight and Bromide Sensitised Christmas Cards. Sold by the Leto Photo Materials Co., Ltd., Rangoon Street, London, E.C.

The ingenious idea of combining a seasonable greeting with pictorial postcard craze, as embodied in these cards, strikes us as an exceptionally happy one, for it enables one to save considerable outlay on a too frequently unsatisfactory card and yet send something which will be a kindly reminder and please some one, for there

so many now who collect picture postcards that there can hardly be a house without a collector. These cards are to be obtained in the self-toning, gaslight, or bromide varieties, and in three sizes: the "Mikro," $3\frac{1}{2}$ by $2\frac{1}{4}$, the Court, quarter-plate size, and the ordinary size, $3\frac{1}{2}$ by $5\frac{1}{4}$. All have rounded corners, and each packet contains two masks, and, for the development varieties, strips of paper for trial exposures. We have utilised our samples for making Christmas and New Year cards that many of our friends will receive.

"Lumières Chromogènes." Sold by the Lumière N. A. Company, Bloomsbury Street, London, W.C.

These are small glass tubes containing mixed powders of uranium, iron, and copper compounds and are intended for toning bromide and gaslight papers and lantern slides, and also may be used in the case of uranium and copper, for intensifying negatives. Each bottle is a small spoon, which holds two and a half grains, which is sufficient to make up about two ounces of the desired solution. The method of using them is precisely the same for practically a five per cent. solution being made, and the print or lantern slide after being well wetted, is immersed till the desired tone is reached, and it need then only be washed for about a quarter of an hour, or till the whites are pure. The convenience of having constant and freshly-made solutions which act well, will be appreciated, and with a set of three tubes we have obtained tones varying from sepia to blood-red, blue, green to violet, brown, and crimson.

The "Silentus" Shutter. Sold by the Altrincham Rubber Company, Altrincham.

This shutter is specially devised for studio work, but is applicable in all cases in which absence of noise is a desideratum. The chief features about it are that it requires no setting, and by aid of exposures from about one-eighth of a second to any period of time can be given by merely pressing on a rubber ball, which raises a curtain, and for prolonged-exposures an ingenious metal clip grips the tube, keeps the lens-exposed till the required exposure

It is so noiseless in action that it can be operated without the photographer's knowledge, and can be fitted before or behind the lens, or inside the camera. It is made in all the usual sizes, and is a well-made and efficient instrument.

Magnesium Powder. Sold by A. E. Staley and Co., 19, Thavie's Inn, Holborn Circus, E.C.

The well-known photochemical works of Dr. Krebs, for whom Messrs. Staley are the sole English agents, have issued a series of papers containing pure magnesium powder in various degrees of fineness, and which is specially intended for blow-through lamps. The necessity of magnesium powder for flashlight, free from grease and mechanical impurities, is generally acknowledged, and the advantage of being able to obtain the same in varying degrees of fineness, as to make it suitable for all styles of lamps and varying pressures, is obvious, as the more free the particles are from one another the more perfect must be the combustion and, therefore, the better the light.

"Tyo" Bromide Toning Solutions. Wells and Co., Southgate, London, N.

Toned bromides are now very much in evidence, and here we have a solution for producing the popular brown tone easily and with little, if any, chance of going wrong. It is sold in two solutions, the first bleached in one, rinsed in water, and then placed in the No. 2 solution until the desired brown tone has been secured. On enamel paper brown tones very closely resembling ordinary P.O.P. can be obtained by bleaching and then developing with any ordinary developer weakened considerably. Bromide prints can, by the use of "Tyo," be reduced, also negatives. Altogether the solution is a very handy one for all photographers to always have at hand.

"Royal Standard" Plate. Cadett and Neall, Limited.

Examples of these new plates have been sent us by the manufacturers, Messrs. Cadett and Neall, Limited. They are made in two kinds, one for giving black tones and the other for giving warm tones by direct development. The black tone plates, we find, give a sufficient range of tones for all ordinary purposes. The plates are extremely easy to use both for contact and reducing, they develop easily and quickly with any ordinary lantern plate developer, but we give below the formulae specially recommended:—**Metol Developer**—A.: Metol, 40 grains; sodium sulphite (cryst.) 2 ounces; potassium bromide, 10 grains; water 20 ounces. B.: Washing soda, 5 ounces; water, 20 ounces. This developer works more slowly than the next, about one and a half to three minutes giving brilliant slides. **Hydroquinone Developer**—A.: Hydroquinone, 124 grains; sodium sulphite (cryst.), 100 grains; potassium bromide, 16 grains; potassium metabisulphite, 10 grains; water to 20 ounces. B.: Potassium hydrate, 180 grains; water to 20 ounces. Equal parts of A. and B. at a temperature of 60° will give black images of medium density; development will take about half a minute. If the developer should work too quickly, it may be diluted with an equal quantity of water. Or, the Ferrouranilate developer may be used:—A.: Neutral oxalate of potash, 1 part; dist. water, 4 parts. B.: Sulphate of iron, 1 part; citric acid, one-hundredth part; dist. water, 3 parts. C.: Potassium bromide, 1 part; dist. water, 100 parts. A. 100 parts, B. 25 parts, C. 10 parts. This will give grey-black images, and medium density. For long exposure and the use of the following developer, warmer tones can be obtained:—A.: Pyrogallie acid, 90 grains; potassium metabisulphite, 90 grains; ammonium bromide, 360 grains; dist. water to make together, 20 ounces fl. B.: Ammonium carbonate, 20 grains; liq. ammonia .880, 380 minims; dist. water to make together, 20 ounces fl. Equal parts of A. and B. to make developer. Development will take about three minutes. This will give you rich brown images. The instructions are very fully set out, and full particulars for exposing, intensifying, toning, clearing, etc., being given. Now that the lantern season has commenced these plates should at once become very popular.

CAMERA HOUSE JOURNAL is just to hand for this month. W. L. Butter and Sons' little monthly trade organ keeps up its bright and interesting character.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
28.....	Camera Club.....	<i>Experiments with Liquid Air and Boiling Iron.</i> Mr. Claude Vautin, M.I.M.E.
28.....	Society of Arts	<i>Musical Wind Instruments.</i> Mr. D. J. Blackley.
28.....	Southampton Camera Club	<i>The Photography of Colour.</i> Illustrated. Mr. Charles B. Howdill, A.R.I.B.A.
28.....	Luton Camera Club	<i>Carbon Printing.</i> Demonstrated. Mr. John H. Gair, F.R.P.S.
28.....	South London Photo. Society	<i>Lantern Slide Making.</i> Mr. E. R. Bull.
28.....	Hackney Photo. Society	Members' Auction.
29.....	Nelson Photographic Society	<i>Across Siberia.</i> Mr. John Foster Fraser, F.R.G.S.
29.....	Brentford Photo. Society	<i>On the Use of the Lens.</i> Mr. Hilton Grady.
29.....	Devonport Camera Club	<i>The Focal Plane Shutter and its Use.</i> Mr. Walter Klibbey.
29.....	Birmingham Photo. Society	<i>Photography Prize Slides.</i>
30.....	Everton Camera Club	Members' Lantern Slides and last day for all Competitions.
30.....	G.E.R. Mechanics' Institution	Judging of First Set of Slides and Prints in Members' Competitions.
30.....	Boro' Poly. Photo. Society	First Social Evening.
30.....	Cricklewood Photo. Society	Beginners' Night.
30.....	Society of Arts	<i>The British Canals Problem.</i> Mr. Arthur Lee, M.P.
1.....	Dec.	
1.....	London and Prov. Photo. Assn.	Paper by Mr. W. T. Wilkinson.
1.....	Camera Club	<i>British Rainfall.</i> Mr. H. R. Mill, D.Sc., LL.D.
1 to 3	North Middlesex Photo. Soc.	Annual Exhibition.
1.....	Liverpool Amateur Ph. Assn.	<i>Winchester.</i> Dr. J. W. Ellis.
1.....	Hull Photographic Society	<i>Hypo-Alum Toning of Bromides.</i> Demonstrated. G. F. Bristow, Jun.
1.....	Gateshead Camera Club	<i>Lantern Slides.</i> Demonstrated. Mr. A. B. Gardiner.
1.....	Richmond Camera Club	Lantern Night.
1.....	Watford Camera Club	<i>Gunn Dichromate.</i>
1.....	Rontgen Society	Paper: Dr. W. Cotton.
1.....	Southport Photo. Society.....	Exhibition of Prize Slides and Demonstration of Various Photographic Apparatus. Thornton Pickard Manufacturing Co.
1.....	Leigh Photographic Society	<i>Rising to the Occasion.</i> Illustrated. Mr. W. D. Welford, F.R.P.S.
2.....	Glasgow Southern Ph. Assn.....	Social Evening.
2.....	Boro' Poly. Photo. Society	<i>Reduction and Intensification.</i> Mr. A. Beeding.
2.....	Oroydon Nat. His. and Sc. Soc.	Exhibition of Photography Prize Slides, 1904.
2.....	Aberdeen Photographic Assn.....	Enlarging Demonstration.

KINGSTON PHOTOGRAPHIC SOCIETY.

THE annual general meeting of the society took place at the Sun Hotel on Monday last week, the Rev. G. I. Swinnerton (president) in the chair. All the old officials were re-elected with the exception of Mr. W. F. J. Hodgson, who, much to the regret of the members, is leaving the neighbourhood. The vacant place on the committee was filled by the election of Mr. A. J. P. Hayes. Mr. J. Schlittie will occupy Mr. Hodgson's place on the committee of the Photographic Record. It was proposed by Mr. W. Montague Robertson, seconded by Mr. B. G. Cooper, and carried unanimously, that Mr. Benjamin Carter be elected an honorary member of the society. Mr. Robertson took the opportunity of expressing the feeling of the members with regard to the unfailing exertions of Mr. East on behalf of the society in the past, and pointed out that it was mainly due to these exertions that the society was in such a flourishing condition at the present time; also how much his absence in South Africa would be felt. It was unanimously agreed to send a message to Mr. and Mrs. East, on behalf of the society, wishing them a very prosperous journey and safe return. Referring to the summer excursions, Mr. Hayes said he wished that more members would avail themselves of these opportunities for picking up hints from other workers with regard to photography, and Mr. Robertson remarked that he had learned many valuable lessons from past excursions with the Camera Club. The remainder of the evening was occupied by a show of interesting slides by various members of the society.

DEVONPORT CAMERA CLUB.

LAST week Mr. J. Batten, a member of the club, gave a lecture on "Stereoscopic Photography." The lecturer remarked that he considered that stereoscopic photography represented the highest development of the realistic side of the art. Compared with the stereoscopic

slide, an ordinary picture, however well made, looked flat and lifeless. Viewed in the stereoscope, photographs stood out in relief, and it was sometimes difficult to persuade themselves that they were not looking at solid reality. Mr. Batten described the methods of producing stereoscopic photographs, and exhibited a number of interesting specimens, as well as a camera of his own construction. The lecturer was heartily thanked, and the president was congratulated on his success at the Hackney Photographic Exhibition and at the Crouch End Social Union's exhibition.

WOODFORD PHOTOGRAPHIC SOCIETY.

NOVEMBER 16.—Mr. H. Wilmer, F.R.P.S., in the chair. Mr. H. Main, B.Sc., F.F.S., gave his lecture on "Insect Photography." Mr. Main commenced by urging the need of specialisation in photographic work, his own particular line being that of the photographing of insects, chiefly butterflies, moths, and their ova, larvæ, and chrysalides, in their wild state, i.e., not merely when dead and set in a collection.

Mr. Main showed a series of 120 most remarkable lantern slides, many of which evoked hearty applause, and all of which were followed with keen and intelligent appreciation and interest, owing to the manner in which Mr. Main infused the breath of romance and popular interest into the dry bones of his science, for it must be remembered the evening's lecturer holds a very high position in the world of entomology, whilst his hearers were mostly laymen in this respect.

LEWES PHOTOGRAPHIC SOCIETY.

A MEETING of the Lewes Photographic Society was held at the Town Hall last week, when the President, Alderman G. J. Wightman (Deputy-Mayor) delivered his annual address. The president said it must interest all photographers in England to know what a very large number of awards had been won by their country in the St. Louis Exhibition, and it must be very satisfactory to them in Sussex to know that Mr. Job, of Hove, had been awarded a gold medal there. One could not take up the daily or weekly newspapers without being very much struck with the wonderful amount of process work—of which photography was the basis—there was to be seen, and there was no doubt a very large field for this kind of enterprise, and the future, he thought, would show a greatly increased amount of it. Alderman Wightman commented on the absence of artistic effect in some of the illustrated papers—"It is a photograph and in it goes." He regretted he had not been able to attend the London photographic shows; there seemed to be a good deal of difference of opinion about the quality of them. There was a good deal, he believed, in what was said about giving a picture a good frame, and also a lot of truth in the assertion that portraits exhibited were simply pictures showing little white noses coming out of great black backgrounds. As to the picture postcard passion, this was being taken up to a startling extent, and the postcard makers must be reaping a very rich harvest. Touching on the kind of camera of the future, the president commented on the reflecting camera, the chief point of which was that they got a reflected image of the exact size and subject that they were about to take, up to the very moment of exposure. To him it was just the thing that they wanted, and was one which must hold the field in the future. In conclusion, he hoped they would have numerous entries in the competitions and a successful year.

CROYDON CAMERA CLUB.

NOVEMBER 16.—Mr. Sellors having originated a gum-bichromate competition of a somewhat novel nature, the evening was devoted to judging the entries sent in and to a general discussion. Under the rules the competitors had to mount side by side a straightforward print on platinotype, P.O.P., or the like, and a gum picture from the same negative. A specially made graduated slip was supplied, from which a print had also to be made. Technical merit alone was to be considered, irrespective of any artistic qualities, which for once in a way had to take a back seat. Mr. Hugh Allen was adjudged the winner, Mr. Lepine Smith being a close second. Certainly Mr. Allen's gum reproduction was remarkable for gradation and detail, and close resemblance to its P.O.P. neighbour.

Mr. Packham, one of the judges, congratulated all on the excellence

of the results sent in, and Mr. Allen in particular. He well remembered, when the process was revived, with what laughter it received by the scientific photographer. It had, however, managed to survive, and the fact that artistic results were possible from photographic basis was, in his opinion, a sufficient justification for its existence. He thought, moreover, that all credit should be given to the worker who, by "faking," produced results definitely aimed at.

In the conversation which ensued Mr. Terry said that, fired with ambition to obtain the medal offered, he purchased the necessary appliances, coated his own paper, and set to work. At the start he obtained two very creditable pictures. One, for instance, could be seen at a glance which was the right way up. These two were, however, last, for on all subsequent occasions the gum and pigment dissolved away, leaving the nice clean paper behind. He somehow felt he was not worthy of the process and was going back to carbon and platotype. With Mr. Larkin the case was different. He had scrupulously followed all instructions, but the pigment coatings in every place refused to budge; he could wish for nothing more adhesive.

ATTERCLIFFE PHOTOGRAPHIC SOCIETY.

THE annual general meeting was held last week, Mr. A. Birtles being in the chair. The secretary's and treasurer's reports showed the society to be in a flourishing position, both numerically and financially. The following officers were elected for the ensuing year:—President, Mr. F. H. Barnsley; vice-presidents, Messrs. A. Birtles, W. Driess, W. J. Mills, and J. H. Gosling; treasurer, Mr. S. Hughes; Council, Messrs. J. R. Whitehouse, G. Armitage, A. Groves, J. Moxon, F. Butcher, M. W. Tallent, J. M. Newman, L. Havenhand, and Osborne; secretary, Mr. G. Walton, 57, Ditchingham Road; assistant secretary, Mr. H. M. Fisher, 37, Cruise Road, Ranmoor. The programme for the next session, of which a forecast was given, promised an excellent course of lectures and demonstrations.

WHITBY CAMERA CLUB.

NOVEMBER 15.—Mr. Brown, in the absence of Mr. French, presided over a well attended meeting. He first called upon the Hon. Secretary, Mr. Parkinson, to read the result of the first club competition. Mr. F. M. Sutcliffe said in his award (writing to Mr. Parkinson):—"I think you will agree with me that there is a great improvement in the work sent in by the members of your camera club this month. No doubt the fine summer has had something to do with this improvement, but, after all, the sun does the work; our cameras and ourselves are the tools. It is very difficult to say which of the prints is the best. Nos. 24, 25, 18, 17, 1, 7, 2, 14, 18, 21, 22, and 5 are all good. Of these I place Nos. 24 and 25 first, because they are more original in treatment than any of the others. The photographer who did these chose the subjects for their beauty of line and beauty of mass, not because they were considered good stock subjects. In each case the dark mass of the tree in leaf stands out vigorously, and in each print the red makes a pleasing mass of white as a contrast. The prints are neither quite as perfect as they would have been had the high lights, sky, and the road been rather lower in tone. It is difficult nowadays to buy a printing paper which does not render the highest light falsely. The paper-maker seems to cater for the beginner, who makes his negatives perilously thin. No. 18 is almost as good as 24 and the taste shown in the mounting is to be commended. What it misses is concentration. There is no part of the picture which calls the attention of our eye. It is like a sermon which sends us to sleep. It is weak where 24 and 25 are strong, and it is harmonious where the two are hard. No. 17 is very poetical, but suffers from too much mount. Imagine this without its grey surrounding and white line—how much sweeter would it not be! The photographer is to be congratulated on the clever way he has put the falling water to one side of his picture, and on the amount of subject included. The dome is in exquisite taste, and but for the Christmas-cardy style of mounting I should have put this higher." Mr. Sutcliffe went through the whole of the twenty-five prints submitted, dealing out words of help, praise and blame, which, no doubt, the members will put to good use. Mr. Brown then, amid applause, handed Mr. Gray the telescope tripod given as a prize by Mr. Bruce. He then called upon Mr. Slater to address the meeting. Mr. W. F. Slater, F.R.P.S., who was demonstrating Messrs. Beck's specialities, then gave a most interesting and useful explanation of the principle and uses of various

lenses, beginning with the simplest lens of all, which, by the way, is the pinhole. From this he went to the spectacle lens, the biconvex or meniscus lens, and the symmetrical or rectilinear lens. The effect, and functions of stops were explained; the various defects of lenses; the principles and uses of the telephoto lens were dealt with; and Messrs. Beck's lenses were explained and their properties described. The lenses shown round; also the most up-to-date cameras made by Messrs. Beck were fully explained and passed round for examination, and, finally, a series of slides from negatives by various Messrs. Beck's lenses were shown. The proceedings, which lasted two and a half hours, were of the greatest interest throughout. The Chairman tendered Mr. Slater the heartiest thanks of the club for his endeavours to instruct them.

BURTON-ON-TRENT PHOTOGRAPHIC SOCIETY.

On the 7th instant Mr. Fred W. Edwards gave a lecture and demonstration before the members of the above society at the Y.M.C.A., on "Evolution of Photography—a marvel of Science." Mr. Edwards said they had to hark back several centuries to discover the germ from which photography sprung. In the thirteenth century Albertus Magnus, experimenting with the metal silver, noticed that when he rubbed some nitrate of silver on his skin it was soon stained a dark brown when exposed to daylight. Magnus merely observed this fact, and offered no explanation, and was apparently ignorant of the light passing the silver nitrate to discolour the skin. For nearly 300 years after this the subject lay dormant, until Fabricius, in the sixteenth century, observed that chloride of silver darkened the surface, but he, like Magnus, never suspected the reason. In the seventeenth century Robert Boyle (the discoverer of Epsom Salts) and Robert Boyle, working independently, observed the changing of chloride of silver, but neither of them knew the reason. No further advance was made until 1727, when a German physician, Schultz, observed that the darkening of silver was due to the action of light. In 1777 a famous Swedish chemist named Scheele took the matter up and made observations as to the effect of light upon silver chloride. In 1804 Thomas Wedgwood, son of the famous potter, published an account for copying drawings on glass. He took a solution of silver nitrate, poured it in a dish. He floated the paper for a few minutes and dried it in the sun. He then placed a leaf on the top and exposed it to the light, and he had to exhibit his pictures by artificial light because he could not fix them. The next person who took the subject up and carried it forward was a Frenchman named Niepce, who made paper negatives, but was unable to make a positive from them as the negatives went black all over, being unfixed. To Louis Daguerre, another Frenchman, is given the chief honour in connection with the discovery of photography. He started with iodide of silver, and one day made a most wonderful discovery. He had previously placed in a cupboard with other chemicals some plates which had been under-exposed and with no visible image on them, but looking at them later on he found a picture on every one. He immediately came to the conclusion that the effect must have been produced through the operation of some chemical substance which was lying in the cupboard, and by investigation he found that the cause was a dish of mercuric iodide. He also discovered the secret Wedgwood failed to find—how to fix a picture in ammonium salt. In 1839 Sir John Herschel applied hypo-sulphite of soda for the fixation of Daguerre's picture—a marked advance in photography. Mr. Edwards dealt at length with the discoveries made by Fox Talbot and Frederick Scott Archer, who worked out the beautiful wet plate collodion process in 1850. Many busy hands were at work to produce a collodion dry plate, prominent among them was our great local scientist, Sir William Abney, of Measham Hall, whose list of discoveries would occupy a whole lecture. Perfection with collodion dry plates was, however, found an impossibility, and the gelatine emulsion process was introduced by Dr. Maddox, of Southampton. This process, with improvements, is still used to-day. Mr. Edwards, before concluding, dealt with colour photography, the

discovery of the wonderful X-rays, and the latest wonder of photography—that of telegraphing a photograph.

Commercial & Legal Intelligence

BEFORE Mr. Registrar Hope last week a sitting was held for the public examination of Mr. Charles Hicks Eykyn, described as of Eaton Terrace, S.W., process engraver, and the debtor stated, in reply to Mr. W. P. Bowyer, assistant official receiver, that on coming of age in 1892 he received £10,000 from the trustees of his grandfather's will. He then contributed £300 towards the expenses of an unsuccessful attempt to exploit a patent invention for the cold storage of meat, and in 1893 he went to Algiers and invested £8,000 as partner in a firm of foreign coaling agents. In 1897 the debtor returned to England, and he had since been engaged in various undertakings, his insolvency being attributed to loss in connection with the Direct Photographure Company, also to other losses, and to his expenditure having exceeded his income. He returned his expenditure since October 9, 1900, at £5,423. The examination was closed, the ranking liabilities being returned at £1,061 and the assets at £65 10s.

THE photograph of a letter decided a case at Birmingham last week, when Mrs. Robinson obtained an order for maintenance against her husband, a brewer's clerk. The couple led a happy life, said counsel, until last July. The husband had been absenting himself from home, but he explained that business had kept him, and the wife believed him. One night, however, Mr. Robinson sat up very late. He wrote a letter, and then fell asleep. Mrs. Robinson came downstairs, read the letter and, realising the importance of it, had it photographed. It was to Mr. Robinson's mother, and ran:—"Mother mine,—I sometimes think that I am an out-and-out rotter. . . . I have met a girl that was made for me, and God help me. I hope it is not blasphemy. I don't know what to do. I suppose I ought to know what to do, and that is to put all these thoughts from me; but the spirit is not willing in this case, and the flesh does not run counter. My darling girl knows how I am situated, and pities me in my fate." A separation was arranged, but Mrs. Robinson forgave her husband, and took him home. The infatuation, however, was too strong, and Mrs. Robinson was subsequently compelled to take proceedings. When the photograph of the letter was handed up to the Bench for examination, Mr. Robinson said, "You need not trouble about it. I wrote it."

SENTENCE on a Canvasser.—Sydney John Halse, thirty-five, canvasser, was indicted for embezzling £2 2s. belonging to Alfred Joseph Hall, of the Western Enlargement Company, Fore Street, Exeter. On the case being called, prisoner made application for the assistance of counsel, as he had no means to engage one. His Lordship said that applied to nine of ten people who entered the dock. He could not interfere in the matter. Mr. Dunnett prosecuted. According to the case for the prosecution, prisoner was engaged in January to canvass Exeter and district for orders for the enlargement of photographs, and to receive moneys from customers. His wages were 10s. a week and commission, and he averaged £2 a week. On September 19, Mr. Newton, a publican of Newton Poppleford, settled an account of 30s. with the prisoner for an enlargement, in respect of which the prisoner only paid the prosecutor 25s. Prisoner also received £5 from Mr. Parsons, of Newton Poppleford, for an enlargement, but he only accounted for £4 10s. Another order was obtained from Miss Smale, of Newton Poppleford, who paid 7s. 6d. on account. Prisoner took the photograph to prosecutor, and said it was that of his wife's mother, asking him what he would enlarge it for. Prosecutor said that as he was an employé he would enlarge it for 6s. Prisoner went to Miss Smale, and said he was very sorry he had broken the enlargement on his way out. He obtained, however, a balance of 13s. 6d. due from Miss Smale. Prisoner did not return to his employment, but sent a letter in which he said he was unable to make up the orders as he was in drink at the time. Prosecutor could keep all commission that was due to him to settle the matter. Prisoner, however, had no running account with his employer, and it was his duty to pay the

money in as he received it. Prisoner alleged in defence it was a matter of account. The jury returned a verdict of guilty, with a recommendation to mercy. Accused was sentenced to four months' hard labour.

News and Notes.

MESSRS. RUSSELL AND SON, of Baker Street, and Mr. W. S. Stuart, of Richmond, have had the honour of taking photographs of their Majesties the King and Queen of Portugal.

The annual report and balance sheet of the Glasgow and West of Scotland Amateur Photographic Association just to hand shows a most promising state of things, and there are few societies with an existence of twenty-one years that can show a bank balance of close on £400.

THE monthly catalogue of secondhand and shop-soiled photographic goods and special bargain list are to hand from the Tella Camera Company, 110, Shaftesbury Avenue, London, W. Some scores of really good bargains are offered at very cheap prices. The company also make a speciality of exchanging cameras, and also of supplying every kind of apparatus on easy terms as well as for cash.

It is with regret that we have to announce the death, on the 11th inst., of William Middleton Ashman, of Old Bond Street, Bath. Mr. Ashman was a well known and prominent figure in the photographic world for many years, and was one of the founders of the old Benevolent Association, the founder of the Bath Photographic Society, and well known at the Photographic Convention. He was a frequent contributor to our pages, and was associated with Mr. Offord in a long series of researches on the manufacture of gelatino-chloride printing-out papers at a time when little was known of the manufacture of the same. These papers are still valuable for reference to all experimenters.

THE Southampton Exhibition. The Southampton Exhibition will be held from December 14 to 21, and comprises the usual classes, with the addition of a special post-card class, for which no fee is required. The judges are Messrs. F. H. Evans, J. C. S. Mummery, F.R.P.S., and H. Snowden Ward, F.R.P.S. Special plaques (size $7\frac{1}{4}$ by $3\frac{3}{4}$) have been designed for the awards, and, as in previous years, it has been arranged for exhibits entered at Hove and Southsea Exhibition to be forwarded carriage free to Southampton, and a special award is offered for the best work at all three exhibitions. Full particulars and entry forms may be obtained from the hon. secretary, Mr. S. G. Kimber, Oakdene, Highfield, Southampton.

PHOTOGRAPHING Trawlers by Searchlight.—H.M.S. "Hebe" arrived at Great Yarmouth last week for the purpose of carrying out an important and interesting experiment in connection with the investigation into the North Sea outrage by the Russian Baltic Fleet. It will be remembered that it has been alleged that there were no hostile warships in the North Sea, and that the Russians mistook the Hull trawlers for Japanese torpedo boats, even after the latter had been illuminated by searchlights from the Russian fleet. After dark, the "Hebe" turned her searchlight upon a steam fishing drifter of the Hull type, which was in motion, and simultaneously a photograph was taken of the little craft, which it is understood will in due course be submitted to the International Commission of Inquiry. The experiment was conducted about a mile off the harbour, and viewed from the shore the drifter bore no resemblance when illuminated to a torpedo boat.

At the last meeting of the British Optical Association, held on Wednesday, at the Mount Vernon Hospital, Fitzroy Square, with Mr. M. W. Dunscombe, of Bristol (president), in the chair, several ideas of importance to sight-testing opticians were discussed. This association was formed in 1895 for the purpose of examining opticians, in order that the public might be protected in some manner from the swarms of unscrupulous men who were selling spectacles existent in this country. The president reported that they had had an exceedingly good financial year, and a large increase of membership, which is obtainable by examination only. They had decided to use the word "Optologist," as meaning one who practises sight-testing as a special feature of his business. A significant inference might be drawn of the power possessed by good organisation from the fact that at this meeting the possibilities of obtaining a charter were discussed, some of the gentlemen present practically guaranteeing the financial support that such a measure would require.

Correspondence.

- * * Correspondents should never write on both sides of the paper, notice is taken of communications unless the names and addresses of the writers are given.
- * * We do not undertake responsibility for the opinions expressed by correspondents.

THE METRIC SYSTEM.

To the Editors.

Gentlemen,—I was very pleased to see your article on "The Metric System," on the 11th inst. There is no doubt that this subject can be too widely discussed, and perhaps you will be good enough to allow me space for a remark or two.

In your article you refer to the "imperial system, and its practicable units and multiples." These units, I take it, are the inch, pound, and gallon, which are in themselves serviceable enough, what of their multiples? To quote only our tables of lengths sufficient to show that our multiples are very far from serviceable, and if anyone is satisfied with our table of square measure I would merely suggest that he work out any ordinary sum of compound multiplication, say 16 square yards, 7 square feet, 32 square inches by and compare the labour with that involved in a similar computation under the metric system.

Or, again, are our tables of capacity satisfactory, with a bus varying in value all over the kingdom, and abounding in similar anomalies? The British Weights and Measures Association admits absurdities in our present system, and it seems only a question whether we shall embark on the process of "patching up," or adopt a system that is now in vogue in so many civilised countries.—I am, Sirs, your obedient servant,

E. JOHNSON, Secretary.

The Decimal Association, Oxford Court, Cannon Street, London, E.
November 16th, 1904.

PACKING DRY PLATES

To the Editors.

Gentlemen,—I have had in use for some time a method of packing dry plates, which is very similar to the one advocated by Dr. Mietz, noticed by you in this week's Journal, and find that it answers admirably. I take large sheets of thin glazed cardboard, about two-thirds thickness, and coat them with a thin solution of brown shellac methylated spirit. When dry they are well rubbed with a clean dust to remove any adhering particles that might abrade the film, and cut up to the required size. Some 10 x 8 plates packed months ago with this cardboard show no traces of reduction due to the packing material such a familiar sight with some commercial plates. I also use the same sheets with additional coating of the varnish in lieu of rubber sheet when platinum printing.—Yours faithfully,

S. T. HARRIS

November 18th, 1904.

THE ANTINOUS RELEASE.

To the Editors.

Gentlemen,—As it will probably interest your professional readers we should be glad if you will kindly mention in your columns that we can supply our Antinous Release, 6ft. long, of a pattern suitable for use on Houghton's studio shutter, at a cost of 5s. The Release, of course, does away entirely with the necessity for constant renewal of perishable rubber parts and the attendant expense of same.—I am, dear Sirs, yours faithfully,

W. WATSON AND SONS.

313, High Holborn, London, W.C.
November 19th, 1904.

THE TRAIL TAYLOR MEMORIAL LECTURE.

To the Editors.

Gentlemen,—I shall be much obliged if you will inform the readers of the BRITISH JOURNAL OF PHOTOGRAPHY that the subject chosen for the seventh Traill Taylor memorial lecture, by Dr. R. T. Glasbrook, Director of the National Physical Laboratory, is "Mode

Physics in Relation to Photographic Optics." Dr. Glazebrook will specially deal with the testing of photographic lenses, and the new optical bench constructed by Messrs. R. and J. Beck, for the National Physical Laboratory, will be shown. The lecture takes place on December 15th, at 8 p.m., at the rooms of the Royal Photographic Society, 66, Russell Square, and Mr. Conrad Beck has kindly consented to take the chair.—Faithfully yours,
P. EVERITT, Hon. Sec.
88, Evering Road, N.
November 19th, 1904.

DUTY FREE ALCOHOL.

To the Editors.

Gentlemen,—I, as manager of this association, have been in correspondence with the Industrial Alcohol Committee appointed by the Chancellor of the Exchequer, with the result that Mr. H. Entwistle, one of our members gave evidence before them on Wednesday last. I think the trades who use collodion to a large extent have not yet realised the importance of this commission to their respective businesses, and therefore thought a copy of Mr. Entwistle's letter to me as to the evidence he gave might be of interest to you, with your paper, circulating, as it does, among such users, and might create an interest in the question.—I am, dears Sirs, yours faithfully,

FRANK BIRD, Manager.

(The Manchester Process and Wood Engravers' Association, 51, Atlantic Chambers, 7, Brazennose Street, Manchester.
November 19th, 1904.

EXTRACT FROM MR. ENTWISTLE'S LETTER.

Dear Mr. Bird,—As arranged, I gave evidence before the above committee on the 16th inst. I was asked for what purposes alcohol was used in the process trade. Of course, I told them chiefly for the manufacture of collodion for negative making, collodion for stripping purposes, as a constituent of developers, as a thinning medium for collodion which has become too thick for use, and as a dehydrating agent in the case of the rapid drying of dry plate negatives. In answer to a question as to the objections to the use of mineralised spirit, I stated that the impurities caused fog, and generally upset the silver bath. Dr. Thorpe did not appear to think, however, that unmineralised spirit, which can be obtained under special Excise regulations was detrimental. I, however, quoted Sir Wm. de W. Abney, who states that methylated alcohol of any kind is not suitable for use in collodion.

I also pointed out the great saving in cost if we were allowed to use absolute alcohol duty free, giving the price for methylated spirit at about 3d. per pound, and the price of absolute alcohol as 4s. 6d. per pound, nearly all of this difference being accounted for by the Excise duty. Dr. Thorpe asked me why I objected to the use of methylated alcohol, and did not object to use Mawson's collodion, which he inferred contained methylated ether? I told him that if the duty on alcohol was done away with there would be no inducement to use methylated solvents of any kind, and that therefore there was less likelihood of anything going wrong with the silver bath, which at present is by no means a rare occurrence. I will, however, let you have a copy of the evidence immediately it comes to hand, as promised per telephone.

BORDER CITY CAMERA CLUB (Carlisle).—The opening meeting of the Winter Session was held at the Liberal Club, Lowther Street, on Tuesday evening, November 8. Mr. R. H. Bevan presided, and read to a fairly representative audience of members Messrs. C. P. Goerz's lecture "What can be done with a Hand Camera," illustrated by 107 excellent slides, showing a large variety of subjects, and capabilities of the hand camera.

Patent News.

The following applications for patents were made between November 7 and November 12, 1904:—

- Cameras.—No. 24,036. "Improvements in photographic cameras." Edgar Samuel Hunter, and William Edward Hanchard.
Cameras.—No. 24,183. "Improvements in or relating to photographic cameras." Alfred Julius Boulton.
Photography.—No. 24,235. "New method of photography and means therefor." Samuel Henry Crocker.
Printing Frames.—No. 24,246. "Improvements in or relating to photographic printing frames." Kodak, Ltd.
Printing Frames.—No. 24,247. "Improvements in or relating to photographic printing frames." Kodak, Ltd.
Coloured Photographs.—No. 24,290. "Process for producing coloured photographs." Gustav Koppmann.
Photography.—No. 24,311. "Improvement in the art of photography." Arthur Henry Gittings.

Answers to Correspondents.

- *** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- *** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- A. Walker, 29, Plymouth Street, Lower Broughton, Manchester. Photograph of John Byrom's House, near Manchester.
A. G. Marshall, 43, Bridge Street, Morpeth. Photograph of High Church Cottages, Morpeth, as a Snow Scene, with Design and Christmas Greetings in Top Corners. Photograph of Lady's Chapel in Bothal Woods, Morpeth.
F. G. Steggle, Stanley House, Midsomer Norton, near Bath. Photograph of the Paulton Rovers Football Club.
G. Cross, 86, Sussex Street, Preston. Two Photographs of Views in Moor Park, Preston.
J. Davidson, 7, Ibrox Terrace, Govan, Glasgow. Photograph of Clyde Steamer "Duchess of Hamilton" in a Storm.

EXPERIMENTER.—The paper you require is known as ferrogallic, and can be obtained from Marion and Co., Soho Square, W.

H. MARTIN.—The book is published in America, but you could obtain it from Dawbarn and Ward, 6, Farringdon Avenue, E.C.

"A SUBSCRIBER."—The paper you used is a collodio-chloride; therefore, when you flooded the print with collodion, it naturally partially dissolved the image-bearing film, and caused it to run into the ridges or streaks.

H. HALES.—If you have copyrighted the negatives you must assign the copyright to purchaser; this would not prevent you selling other negatives. Purchasers of negatives or prints could not copyright unless you gave permission.

ARTIFICIAL LIGHT.—"STUDIO" asks: "Is there a book published on 'Artificial Light for Portraiture in the Studio'? If so, you

will greatly oblige by letting me know where it may be obtained." In reply: See answer to "Inquirer."

"SPES."—Yours is such a purely trade matter that it does not come within our province to advise. We may, however, say that the best way of getting your paper on the market will be to advertise it in the journals. Most professional photographers will test it, and give you a report—of course, for a fee.

A. M. MACDONA.—We are sorry we mistook the purport of your query. Obviously, we cannot know the exact formula, but you probably know Wellington's formula for chloro-bromide emulsion; if not, we will give it you, and this we should advise you to use.

"A. B. C."—Either you did not wash sufficiently between the gold and platinum baths or else the temperature of your solutions varied too much. The defects are the all too familiar blisters which are often met with just at the commencement of the cold weather.

LINE SCREENS.—"BROMIDE" asks: "Will you kindly let me know where a photographic positive of a half-tone process screen may be obtained? Also the probable cost of same?" In reply: The screens may probably be had from Messrs. Penrose and Co., Farringdon Road. If they supply them they will quote prices. We do not know them.

ARTIFICIAL LIGHT IN STUDIO.—"INQUIRER" asks: "Would you be so good as to advise us as to the best book to get on 'Portraiture and Groups by Artificial Light'?" In reply: The late Mr. Slingsby issued a work on flashlight photography (Marion and Co.) some few years ago. "Photo Miniature," Nos. 29 and 31, also deal with the subject.

CELLOID.—"D. D." says: "The paragraph on 'The Manipulation of Celluloid' (issue November 11) is interesting. Now, will you kindly let me know where it can be purchased in sheets, about 1-100th of an inch in thickness? I am in want of a number of sheets 3 ft. long, 5 in. wide." In reply: Sheet celluloid of various thicknesses is supplied by Messrs. Guiterman and Co., Aldermanbury, E.C.

DEVELOPING AND FIXING.—"G. A. D." writes as follows: "A friend informs me that there is a combined developing and fixing solution for plates. Do you know of such a mixture? If so, I should feel greatly obliged if you will kindly favour me with a recipe for same." In reply: The following may be used: Stock solution. Sodium sulphite, 4 ounces; caustic potash (in sticks), 480 grains; Kachin, 480 grains; water, up to 10 ounces. For fully exposed plates take stock solution, 6 drams; hypo solution (one part hypo to five of water), 10 drams; water, 15 drams.

SPOTTY PRINTS.—"TROOPER" says: "I shall esteem it a favour if you can tell me the cause of spots showing on enclosed matt P.O.P. print. They appear directly after toning and fixing, when beginning to wash, and my printer cannot account for them. I am of opinion it is carelessness in manipulation, but I fail to detect precise cause." In reply: If you, a professional photographer, seeing the work done, cannot detect the cause of the spots, we can scarcely be expected to do so by merely looking at the finished print. Evidently they are due to something in the manipulations, which you should be able to detect yourself.

LANTERN LAMPS.—"LANTERN" says: "If the query comes within the scope of your column, I shall be greatly obliged if you can tell me why in oil lanterns the wicks are placed end on to the condenser? Would the light not be greater if the wicks were placed with their broad sides parallel to the condenser, and a further increase of light obtained by arranging them in the form of a flight of steps?" In reply: With the wicks arranged as shown in your sketch (No. 1), the light is far more brilliant, and in every way better, than it would be if they were arranged according to your second sketch. This you can prove for yourself by trial.

BICHROMATED GELATINE.—"PHOTOPHIL" writes: "In making plates for a photo-mechanical process by bichromated gelatine I find

since the cooler weather that in development, no matter what the temperature of the water, the gelatine 'frills' and quits glass. What is the cause? Is it due to the cleaning of glass? Hitherto, I have not used any substratum, as it is very desirable to have absolutely naked glass in the shade and gelatine will sometimes adhere so fast as to bring a flakes of glass rather than separate. Can you suggest a remedy?" In reply: The gelatine film will certainly not adhere to the glass unless the latter is made thoroughly clean. The surface of it should be ground to give the gelatine a hold.

COPYRIGHT.—"OPERATOR" writes: "Two years ago, while operating for a firm of photographers, I took a 12 by 10 negative of a very popular singer. It is the lady's favourite portrait, is constantly being reproduced. It was copyrighted at the time, but the business has passed into other hands and I know the copyright was not transferred. I have prints of the picture, and want to know if I can copyright it afresh in my own name, as I was the actual author. Your kind opinion will greatly oblige, as the same applies to other pictures I have produced." In reply: If the copyright has not been assigned, it is still the property of your former employer. You certainly have no claim whatever to it, as you were paid for doing your work.

MARKED PRINTS.—"PRINTS" writes: "Will you kindly give me a little help upon the following? When fixing enlargements by spray, am much troubled with fixative drying in spots, spoiling the enlargement. Have tried best fixatives, sprays, also spraying at different distances, but to no purpose, so am obliged to stop them instead; but understand there is a slight risk in this, would therefore be pleased to be able to spray satisfactorily. Will you also kindly inform me if plates and carbons can be steamed satisfactorily?" In reply: We scarcely understand what you mean by fixing by steaming or spraying. The proper way to fix bromide pictures is by immersing them in a solution of hyposulphite of soda. In future write on one side of paper only, please.

VARIOUS QUERIES.—"CELLOIDINE" asks: "1. Do you use the weight of celloidine in making up collodion as given in pyroxyline? 2. Which would you choose for illuminant in a large, (a) duplex oil, (b) incandescent gas, (c) plain burner? I have been using acetylene (which is very reliable) but in new premises not convenient; (a) seems reliable more trouble, (b) light value so variable. 3. Re Mr. Farmer's article in the issue for October 23, can you inform where suitable positives from screens can be obtained, what the probable cost for, say, 20 by 16?" In reply: Celloidine is put up in packets, the contents of which, whatever its weight, represents one ounce of pyroxyline. 2. They should employ incandescent gas lights. 3. They may probably be had from Messrs. Penrose and Co., Farringdon Road, London. We do not know the price.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Unfair Competition in the Photographic Industry.

With reference to our apology to Ilford, Limited, which appeared, under the above heading, in our last issue, we much regret that, through a desire to give it prominence, we did not make it clear that it was from the editorial chair, and should have appeared under the heading of "Ex Cathedra." We hasten to rectify any misunderstanding on this point, and to remove also any suspicion of a desire to shelter ourselves by the publication of the letter from Herr F. Dyck, which appears on same page. We again express our regret that we should have been the means of giving any further publication to the misrepresentations that appeared in the "Photographisches Wochenblatt" in the case of Ilford, Limited, v. Westendorp and Wehner, and in which the real decision was exactly reversed, which was in favour of Ilford, Limited, both in the lower and upper courts, and against Westendorp and Wehner, who were the ones found guilty of an improper infringement of the label and trade mark of Ilford, Limited, and condemned in damages and costs accordingly, with an injunction restraining any further continuance of the offence. And we regret still more that, based upon that report, we should have made the remarks we did, entitled "Ilford and German Injustice," and which we admit were quite unwarranted. We offer our fullest and sincerest apologies, with every expression of regret, to Ilford, Limited, for this unfortunate occurrence, and hope it will now be quite understood by our readers that instead of there being any pretence of a ground of complaint against Ilford, Limited, or any foundation for the unjust imputations made upon them, they have been the ones entirely in the right in the matter, and so completely so, that when taking proceedings in German courts against German subjects, they both in the court of first instance and again on appeal, obtained decisions in their favour, with substantial damages.

tations made upon them, they have been the ones entirely in the right in the matter, and so completely so, that when taking proceedings in German courts against German subjects, they both in the court of first instance and again on appeal, obtained decisions in their favour, with substantial damages.

The Illness of Mr. F. J. Mortimer.

Many of our readers will be glad to hear that there is a considerable improvement in the condition of Mr. F. J. Mortimer, the sub-editor of the B.J., and although his recovery from the very serious operation which he underwent about a month ago is likely to be somewhat tedious, we are hoping to see him back in his accustomed chair before the close of the year.

A Lovely View Saved.

There are probably very few photographers who do not by repute or actually know that particular region of which Bettws-y-Coed is the centre, and which is so rich in work for the camera user, and therefore they will be glad to hear that as a result of the resistance offered by local authorities, on the score of danger to scenery, to the projected railway from Snowdon to Bettws-y-Coed, a compromise has been arrived at. With regard to the Swallow Falls, it is agreed that the proposed tunnel of 155 yds. should be increased in length to 275 yds., the line to be laid for the remainder of the distance in a cutting to be screened by planting and rough walling. This, it was claimed, would protect the cliffs from disfigurement. The District Council asked for a level crossing over the road near Pont-y-Pair, in the village, rather than a bridge 20 ft. high and an embankment, and this the promoters agreed to. The Board of Trade afterwards accepted the settlement of the parties, subject to clauses to be drafted.

The British Science Guild.

Under the above title an organisation has recently been established, the objects of which are briefly: (1) To enforce the necessity of applying scientific method to all branches of human endeavour; (2) to bring before the Government the scientific aspects of all matters affecting the national welfare; (3) to promote and extend the application of scientific principles; and (4) to promote scientific education. Sir Norman Lockyer is the President of the Organising Committee, Lord Avebury the Treasurer, and Lady Lockyer the Honorary Assistant Treasurer. The Guild has already been joined by a considerable number of Fellows of the Royal Society and other influential persons. The contribution required from subscribers is merely nominal, 2s. 6d. per annum, with an entrance fee of like amount. Further

information as to its aims, objects, and organisation, can be obtained on application to the Honorary Secretary of the Guild, Mr. C. Cuthbertson, 9, York Terrace, London, S.W.

* * *

Failure of an Art School. Many will remember that some twenty years ago Professor Herkomer established a school of art for students of both sexes at Bushey. At first the school was, we believe, a success, but of late years it has not been, and a year or so back it was found necessary to close it, as it was no longer a paying concern. It was alleged at the time that the students spent more time in studying Nature in the open than they did in studying art in the studios. Be that as it may, the property, which covers about half an acre, was sold at auction last week by order of the trustees for the debenture-holders, and realised £1,300. The starting of a private art school on the lines of that at Bushey was a bold venture on the part of Professor Herkomer, and was deserving of better success than it met with. There are now so many public art schools under Government and municipal auspices that we are afraid private schools on the lines of Herkomer's will meet with but little success from a commercial point of view.

* * *

Cinematograph Accidents.

It is seldom now that one hears of accidents with cinematograph films as compared with what used to be the case when the instrument was first introduced, although there are probably more shows now being given than at any other time. This may be attributed to two reasons: one that the operators with them now know better the nature of what they are dealing with than they did at first; the other is the conditions imposed by County Councils and others with regard to the exhibition of cinematograph pictures. One noteworthy thing at the present time is that when, perchance, there is a "blaze-up," the audience seem to keep their heads instead of being panic-stricken, as used at one time to be the case. This applies equally, we are pleased to say, when there is an alarm of fire in a theatre and other crowded assembly. Last week we read that while a cinematograph show was being given at the Royal Assembly Rooms, Woolwich, the films became ignited and blazed up, and the operator was badly burned about the head and hands. There was no panic, however; the audience left the place quietly, and the fire was quickly extinguished. Still, a film of a non-inflammable nature, as thin and flexible as celluloid, is yet a desideratum—accidents are better avoided than remedied afterwards.

* * *

Exports to Egypt.

In these days of continuous complaint concerning British exports, the following figures will be a surprise to many who are in alarm at the supposed decadence of the country. They are taken from "Export," a Berlin newspaper. They relate to the imports by Egypt of scientific instruments and astronomical and optical appliances. The totals are given in Turkish pounds, the value of which is about $2\frac{1}{2}$ per cent. more than English sovereigns:—

	1901.	1902.	1903.
France	10,533	8,283	12,914
Great Britain...	5,643	7,773	9,014
United States...	4,478	3,201	856
Germany	4,054	3,456	6,147
Austria-Hungary	2,166	1,750	1,554
Turkey	1,214	833	574
Italy	719	868	2,773

It will be seen that England's exports to that country in

1903 exceeded those of 1901 by about 60 per cent. With the exception of the small figures marked down to Italy the exports by Great Britain have been really the most progressive of any country on the list. Even the decline in values in 1902, which is observable for almost every other country, did not take place in the case of Great Britain, but the figures show an advance of 40 per cent. on the previous year. Why should so many Englishmen disparage their countrymen?

* * *

Duty-free Alcohol.

It has long been a crying grievance that the manufacture of certain chemicals and dye-stuffs in this country is heavily handicapped where pure duty-paid alcohol has to be employed, as the methylated spirit will not answer the purpose; whereas in Germany pure alcohol is allowed to be used for manufacturing purposes, upon which no duty is imposed. Some time back a Committee was appointed to inquire into the use of duty-free alcohol, and last week it met, and several witnesses were examined. The permission of the use of duty-free alcohol for industrial purposes would not be the boon to photographers that it would have been when the collodion process was the process of the day. Still, it would be a boon now to many. Some look upon the collodion process as being an obsolete one, but they will possibly be surprised to know that it is still extensively, if not universally, employed by process workers and those who produce commercially enlarged negatives for carbon and platinumotype enlargements. In the manufacture of the collodion ether made from methylated alcohol answers quite well, and its cost is roughly about a shilling a pound; whereas the alcohol costs about three times, or more, this sum. Methylated spirit would do quite well for negative collodion but for two reasons. First, that it is not strong enough—60 deg. to 64 deg. O.P. equal a S.G. of about .830—and it is not allowed to be strengthened by redistillation. When the spirit was first allowed to be sold it could be had of the strength of .805 (commercial absolute) but that was afterwards prohibited. The second reason is that the wood naphtha used for the methylated is very impure. If a pure, or refined, wood naphtha could be used, it would not be harmful. But all samples of the wood spirit for methylating have to be submitted to the Excise authorities before they are used, and if they are found to be anything but of a quite crude nature the use is prohibited.

Toned Bromide Prints.

In the "Photographische Correspondenz" this month a very pleasing toned bromide print is published which must attract the admiration of most, if not all, photographers. The subject is modern Sappho, leaning against a tree in contemplation. The negative is one of Reutlinger's, of superb finish, which displays the whole range of gradation in the paper, which is manufactured by the Neue Photographische Gesellschaft, Berlin-Steglitz. It is known as the Matt N.P.G. No. III. The tone of the print particularly interests us, as it is of a rich, warm sepia shade, obtained by sulphur toning. As it may be possible to produce similar effects upon other makes of bromide paper, we give our readers the particulars of the process. The pictures are developed with ferrous oxalate, well fixed and washed. The toning bath is fixed as follows:—50 grammes of hyposulphite of soda; 300 c.c. of hot distilled water, to which 5 grammes of powdered alum is added; $1\frac{1}{2}$ to 2 c.c. of 10 per cent. solution of silver nitrate; it is only necessary to make this addition to a new, fresh bath, as its purpose is to diminish the rapidity of action. Such a bath is preferable in all cases, and it is indispensable to heat the fresh bath two or three times to 122 deg. or 140 deg. Fahr.

allowing it to cool after each application of heat. The solution should have a temperature of from 100 deg. to 120 deg. Fahr. for use. Toning occupies from fifteen to twenty minutes, but the time is more prolonged with cooler solutions. Any deposit should be removed from the prints with a brush or pledget of cotton wool. A preparatory bath of 20 grammes of common salt per 20 c.c. of water at 70 deg. Fahr. will produce redder tones. Prints which have to be developed with organic developers, such as metol-hydroquinone, show a greater tendency to reddish brown in toning. Old baths, before further use, should be freshened by the addition of an equal quantity of new toning solution.

A New Electric Light Lantern.

At the last meeting of the Physical Society a new form of optical lantern for use with the electric current was exhibited. The particular instrument shown was designed specially for science lectures. The novelty consisted in the use of three Nernst filaments arranged closely together. It is provided with a long range of adjustment for focusing, and can be instantly changed for throwing the picture horizontally or vertically. It can also be fitted with a reversing prism where necessary. We may say *en passant* that the Nernst lamp has not, at any rate among photographers, earned the popularity it deserves. It is capable of giving a light of far greater brilliancy than that obtained from the ordinary incandescent lamps. It has much greater actinic power, and can be had of such size as to compare with the smaller arc lights. Its drawbacks are slight, mainly centring upon the original outlay for the complete lamp, which is much in excess of the cost of the incandescent bulb lamp. Next the light does not instantly appear at its brightest the moment the current is switched on. It takes a matter of twenty to forty seconds to arrive at its full brightness, and this—such is the impatience that characterises modern workers—is considered a great drawback. It can be switched off instantly, however. We reserve to the last a most important characteristic—the cheapness of the lamp in use. We were recently discussing the matter with a manufacturer whose current bill averaged £22 per annum. He had recently had all his incandescent bulbs taken down, and he calculated that the economy of current would in nine months' time cover the cost of his alterations. He would then have his future current at a great reduction of cost. Where lights are intended to be kept continuously burning there can be no doubt of the advisability of adopting the Nernst lamp.

Brass and Copper Half-tone Blocks.

Some years ago, at the Colonial Institute Photographic Exhibition, some half-tone blocks on brass were shown, and since then, brass has been occasionally used for this work, but zinc or copper have practically been held to themselves. Herr Fleck, who is well known as a practical photo-mechanical writer, points out in the "Photographische Chronik" that zinc becomes crystalline and brittle when subjected to the necessary heat for burning in of the enamel print, and that copper, which is not subject to this defect, is much dearer, and that the best etch for this, ferric chloride, is by no means the ideal one. Now he states that the hard brass metal in 0.4 to 0.5 millimetre thickness is the most suitable substitute, and that the etching is quieter and more even than with copper, and, therefore, the dots do not lose in sharpness, and that the burning-in takes place more quickly and more certainly. Further, that a thicker ink may be used, and, therefore, very clean, sharp pulls

are obtainable, which are quite satisfactory. In consequence of the less thickness of the metal, better contact is obtained between the negative and the metal, and, therefore, sharper results are obtainable. Although ferric chloride is an excellent etch for brass, it is not so satisfactory as the following, as this enables one to see perfectly the progress of the action, and does not affect the skin of the operator's hands at all:—

Water	450 parts.
Hydrochloric acid	300 parts.
Potassium chlorate	180 parts.

The mixture should be allowed to stand for a night in the open air and used the next morning, and it may be repeatedly used as long as it remains colourless. We have not actually tried this, but the etch is nothing more than the old solution for making euechlorine, which is an extremely unpleasant gas that at once attacks the mucous membrane. Possibly, however, allowing the mixture to stand twelve hours may improve matters.

A New Rival to Postcards.

In no business or profession is there a better exemplification of the modern axiom that there is no finality in business methods. The photographer with a good business, good returns, and good profits, who thinks he has struck a gold mine, will find before many years are over, if he keep in the same groove, that the lode has given out, that his luck has turned, that his once grand business is dying out. In photography, as in all other modes of business, there is no "resting on one's oars." As we once heard a smart business man say, "You never get there, and the moment you rest, down you go, and rarely come up again." We recently commented on the stereoscope, but that is not an isolated example. Many of our readers will remember the rage there was for cartes de visite: they are now rarely taken at all at some leading studios. If there was one class of business more firmly established, to all appearances, than another, it was the sale of local views, which were stocked at every stationer's shop in the country; process prints and collotypes have killed it. There must be hundreds of thousands of pounds' worth of stock in these shops at the present time the owners of which would be glad to dispose of for so many pence. The postcard mania has now had a good innings, and we must expect a diversion of some kind if it is to retain its popularity. Happily, the photographic view postcard still seems to hold its own, though we learn from the stationers that they already have "bad stock" of many other types of picture postcards. The latest rival is a penny-in-the-slot arrangement for sending not a photograph of a place or a person, but a phonographic record in the sender's own voice. The invention comes from Vienna, and we learn that by dropping in the penny the purchaser can obtain a record of his own voice on a thin gramophone disc, which, under Continental postcard rules, may be fixed on a card and forwarded as a postcard. It is claimed that the disc is made of a newly invented material which is so tough that it will pass through the post uninjured. Of course, the difficulty is the reproducer to enable the recipient to hear his message. This is to be met by a new phonograph, which is to be put on the market for a price not exceeding ten kronen (8s. 4d.). If once this invention proves a success there can be no doubt it will be a serious rival to photo-picture postcards. Our very strong advice is to anticipate it by carrying out our recent suggestion of stereoscopic postcards and cheap stereoscopes, which, if carried out on business principles should, we repeat, lead to a "boom."

PHOTOGRAPHS ON WATCHES, CIGARETTE-CASES, AND THE LIKE.

THERE is evidently a growing taste for photographic portraits on such articles as watches, gold or silver cigarette-cases, matchboxes, etc., and the jewellers who undertake to get this class of work done usually charge a pretty good figure for it. A little while ago we were shown a watch on the dome of which was a portrait for the production of which guineas had been paid. Of course the jeweller did not do the work himself, but clearly he knew where to get it done, and exceedingly well done it was. Some year or more ago we saw a similar picture on a watch case which, it was alleged, had to be sent to Switzerland by the London jeweller for the work to be executed there, because it could not be done here. This picture and the other referred to were unmistakeably by the carbon process.

It may be remembered that in 1901 we published a method of producing photographs on jewellery, trinkets, etc. (see page 451 of the volume for that year). The method then described was by the collodio-chloride process, but there is no question that pictures by the carbon process are, theoretically, at least, more permanent than those by any silver one.

As the carbon method of producing pictures of this kind may be of service to many of our readers, we shall here describe it in detail. We shall assume, at once, that the reader is already quite familiar with the practical working of that process, for we may here say that any one who takes up the working of this process for the first time, and attempts to apply it to the present purpose, must not expect to meet with any great success in his first few essays. It goes without saying that it is the double transfer system that must be employed—the picture being developed on a temporary support, and then transferred to the article desired. It will at once be seen by practical workers that the ordinary commercial flexible support is not suitable for the work, for the reason that it is too thick and unyielding to be pressed into sufficiently close contact on a convex surface, such as the dome of a watch-case, for example, to obtain a perfectly finished transfer. It may, however, sometimes be successfully used for quite cylindrical articles.

For the above reasons it will be obvious that a more flexible and yielding support must be employed. One is the indiarubber support as first used by Swan; another is a film of collodion. We will deal with the former first. Some thin "foreign post" paper, the thinner the better so long as it will withstand the warm water in the development, is coated with a solution of indiarubber about the consistency of thin treacle. The best way of obtaining this is to get a tin of solution from the rubber stores and thin it down with benzole to the required consistency. It is poured into a dish and the paper floated upon it and then hung up for the benzole to evaporate. The paper had best be coated a few days before it is required for use, so as to ensure that all the solvents of the rubber have thoroughly evaporated.

This indiarubber support is used in precisely the same way as the ordinary flexible support—the exposed tissue is squeegeed upon it, developed, and then allowed to dry. The picture need not be alumed, indeed, it will be better

for our present purpose if it is not. The picture is now ready for transferring to whatever may be required, which for the moment we will assume to be the dome of a watch-case. It is unnecessary to mention that it must be removed from the watch, this a neighbouring watchmaker will do for one. The dome is then cleaned with benzole to remove all traces of grease or dirt. It is then coated on the outer side with a solution of gelatine containing a little chrome alum such as that used for double transfer paper. The following is a good formula to employ:—

Nelson's No. 1 gelatine $\frac{1}{2}$ oz.
Water 10 oz.

Chrome alum, dissolved in 1 oz. of water, 6 grains.

The dome is evenly coated with this and allowed to dry. To make the transfer neatly, trim the print to the required size and put it and the watch dome in cold water for ten minutes or so. Next put the latter in warm water at about 105 deg. to 110 deg. Fahr., until it just feels slimy. Then take the print, having previously marked it as a guide to position, and put it into the warm water and bring it in contact with the dome, of course avoiding air bubbles, and remove the two and press in close contact with a soft dry handkerchief, gently rubbing towards the edges with the fingers so as to remove all superfluous water. It is then allowed to become thoroughly dry spontaneously. When dry, the back of the paper is moistened with benzole, and after resting for a minute or two the paper can be slipped off, leaving the picture firmly attached to the metal. Should any rubber remain on the picture it may be rolled off with the finger, or removed with benzole. It now only remains to varnish the work. The proper varnish for the purpose is the "Zapon No. 3 enamel," as supplied by the Fredk. Crane Company, 22, Newhall Street, Birmingham. This is practically a cold lacquer, and when dry is as hard and durable as the lacquer on our lenses. It is simply flowed over and drained off, and it dries in a few hours.

We mentioned just now that collodion might be used as the temporary support, and perhaps on the whole it is the best to employ. Here is the method with this. A glass plate, after being waxed, or prepared with French chalk, is coated with ordinary enamel collodion thickened with two or three grains per ounce of pyroxiline, so that it yields a thick film. After the collodion has thoroughly set the plate is put into a dish of water to soak, and is afterwards washed under the tap to get rid of the solvents of the collodion. The exposed tissue is then squeegeed on that, developed in the ordinary manner, and allowed to dry. When dry the film can be stripped off and trimmed, and then mounted on the metal as just described. It is a good plan to trim the picture while it is still on the glass—a wheel trimmer and zinc shape is convenient for the purpose. The collodion film has an advantage over the rubber support, inasmuch as it is transparent, so that air bubbles can be seen, and the picture the better arranged in position. After the transfer, the collodion can be dissolved off with a mixture of ether and alcohol.

In conclusion it may be mentioned that for carbon pictures on metal a tissue should be selected that contains a large proportion of pigment to gelatine, and should also be printed from a tolerably thin negative, so as to avoid a high relief in the image, which is objectionable in this class of picture, and, moreover, it serves to indicate the method by which it has been produced, which, in some instances, it is not desirable to do.

The current number of the "Practical Photographer" is devoted to retouching, and contains many practical and helpful wrinkles from some well-known professionals.

NOTES AND NOTIONS.

BY THE AMATEUR OPTICIAN.

FLASH-LIGHT photography is not a branch of work that the average professional makes an enthusiastic study of. He does not often "run after" such work. I refer, of course, to such subjects as public dinners, dances, and such-like doings—as a lay contemporary alliteratively puts it. I have been much interested in the recent experiences of a professional friend who has been rather successful in this direction; he, in fact, got several commissions by reason of the satisfaction given to a certain club whose annual dinner he has photographed for three years in succession, but all these have been done in one large room or hall. He made a preliminary trial, and by the lesson thus learnt has been able to take groups there since with unflinching certainty. So far all was well, the trouble and anxiety came when the work necessitated a total change in the quantity and distribution of the illuminant; in other words it was a new group under different conditions—size, shape, and character.

Only by the aggregation of detailed experiences do we arrive at results definite enough to be looked upon as safe guides in photographic practice, hence no apology is made for entering into a little more minutiae than might be thought necessary or appropriate. The place therefore was a public swimming bath—dimensions 40 yards by 12 yards, lighted by a number of incandescent electric lamps of no value photographically—the subject, a group of bathers, not in motion. An attempt was

Fig. 1.

made, of course, to reproduce as far as possible the conditions to which one was accustomed, taking the precaution to add a little extra illuminant, e.g., referring to the annexed diagram (Fig. 1) a, b, c, and d, represent approximately the shape of the building. The apparatus comprised a 10 by 8 camera and rapid rectilinear lens of 11 inches focus. Well, the camera placed midway down one side of the bath; say, at the point marked X, takes in an area equal to E F or G H, and groups arranged there respectively turned out to be in every way gratifying. The illuminant, placed above and a little to the rear of the apparatus, consisted of three seven-second flash candles, and the lens was stopped down to *f*16. But with the camera placed at a or g, a group arranged about the line H to X was not nearly so good, even with an additional candle a few yards down on the right hand side and well out of the line. An inspection of the photograph taken from the point A shows that three candles (7 sec.) there, and one each at three other places down the side at equal distances, would have properly illuminated the building; by a slightly different arrangement of the bathers and careful focussing, the whole length of the bath would be taken in clearly. Short of electrical means I fail to see how all these candles are to be ignited simultaneously, it would certainly take some drilling to get four persons to accurately do the trick. In order to test the matter, the more readily as the material was in evidence, I rigged up the wires—enough for the purpose—and found that to ensure the ignition of four pieces of touch paper simultaneously, it was necessary to use a battery repre-

senting 6 volts, i.e., three large bichromate cells. The arrangement was as in Fig. 2, the line wires (ordinary bell wire) were bared at five different points, and between the points 1, 2,, 4, 5,, short (one inch) lengths of fine platinum wire, No. 26 S.W.G., were inserted as shown. Connection to the battery was then made as in the figure, and on making contact at C the platinum wires immediately became red hot, sufficiently so to light the gas, a cigar, or the touch paper aforesaid.

I use a 50-c.p. lamp now and then for the purpose of charging a small accumulator, recently it came in very usefully when I happened to be photographing a rather dimly lighted interior where, however, electric lamps of the ordinary candle powers were installed; the dodge was to get a few yards of the silk-covered twin wire used by electricians, connect one end to the lamp and the other end to a plug, this done, one of the small lamps, out of the view, was removed and the plug inserted in its place. The 50-c.p. lamp was then arranged in the position required and served its purpose very well indeed.

A good quantity of blotting paper is used by photographers for the purpose of backing up the negative in the printing frame, interposing a comparatively soft, and certainly an absorbent, packing between the print and the hinged back of the frame. Few people, I imagine, are aware of the amount of moisture which ordinary, everyday, commercial white blotting paper habitually contains. Just lately, preparing some blotting paper for work connected with induction coils, I cut a number of sheets into squares, made them into a parcel, and weighed the package and found it to be 13½ oz. The parcel was placed

Fig. 2.

on the rack over the kitchen stove and allowed to remain there for a few days. When again weighed it was found to be exactly 10 oz., and to have lost 3½ oz. of moisture. This seems a big percentage, but the weights were carefully checked and recorded. It is clear that blotting paper is not nearly so dry as it appears to be, and that for use in the printing frame other materials—thin felt for instance—might be preferable. Best of all is no doubt sheet rubber. It is evident that blotting paper used as indicated requires to be dried occasionally.

I find that our mutual friend "Free Lance" has not quoted me correctly; he refers to photographs, whereas I distinctly said *negatives*, and I certainly think that 3s. 6d. for a half-plate negative, i.e., for post-card printing, is not good enough. Then with regard to the stereos, I said nothing about eighty prints; the quotation was for taking twenty stereoscopic negatives and supplying one print and one transparency from each, at the price of twenty shillings per set. Here one may say that the prints would count as small value compared to the transparencies, and I hardly gave them a thought. Twenty shillings each, therefore, for taking a negative and printing therefrom a transparency and one print mounted; twenty pounds sterling—that is to say—for the lot was, considering all things, reasonable (?).

The use of isochromatic plates is certainly on the increase, but results are very disproportionate, even more so than the average amongst amateurs. This means very little after all,

for I have only six customers, all told, for these plates; one of them occasionally shows me a result which pleases him—so I suppose there is nothing more to be said—but it is evident that the man is easily satisfied. On the whole one is inclined to think that the use of isochromatic plates may become indiscriminate; that for most purposes users would fare better—and oftener—with ordinary dry plates. One of my customers, who likes to do everything connected with photography in a scientific way, never by any chance uses any other than isochromatic plates; he uses an actinometer, and a screen, and affects “time” development, with, on the whole, rather surprising results; he seems to be working in the dark all the time and takes what the gods send him in the semblance of a negative as, apparently, the best possible. There are so many factors bearing upon the production of a good negative that a calculated exposure by actinometer, and so many measured minutes in a developer, does not, perforce, bring about the anticipated. However, this is not what I started out to write. One of those clever and versatile writers on the art and practice of photography in the lay press, refers to the subject and gives a formula for the preparation of isochromatic plates, which may be found in several of the more recent “British Journal Almanacs”; as thus:—

PRELIMINARY BATH.

Ammonia	10 minims.
Distilled water	1 ounce.

Bathe the plate in this for two minutes, then immerse for the same period in:—

Erythrosine soln. (1,500)	30 minims.
Ammonia	10 minims.
Distilled water	1 ounce.

Having properly effected this, the writer goes on to say, “*set up on end to drain and dry in the dark room*” (the italics are mine). One wonders, considering the absence of further particulars, whether this writer owns, what may be termed, the average dark room, and whether he has ever tried to dry isochromatic or any other sort of plate in the manner suggested. For my part, with memories of plate making and coating and attempted drying in nearly a dozen different dark rooms, I should hesitate to recommend any such unprofitable procedure. Sensitive films on any kind of support can only be effectively dried in a drying closet of proper—not to say scientific—design and construction, such as may be seen described and illustrated in many back volumes of this JOURNAL. Let the amateur first make something in this way, then with the necessary enthusiasm he will get many hours enjoyment, and, may be, profit out of it; any work which properly requires the equipment of a light-proof drying cupboard is only very ineffectively done without it.

PHOTOGRAPHIC Society of Ireland.—A lecture entitled “The Evolution and Symbolism of the Irish Wheel Cross” was delivered last week by Mr. P. J. O'Reilly at a meeting of the Photographic Society of Ireland, in the Lecture Theatre of the Royal Dublin Society, before a rather small audience, which was no doubt attributable to the inclemency of the weather. Professor J. A. Scott presided. The lecture, which was illustrated by some fine lantern slides, worked on the theory that certain designs were used by the pagan Irish as sepulchral symbols. These designs, or combinations of them, were found to be continued in the Christian era, and were to be seen on Christian Irish sepulchral leacs, or flagstones, of comparatively recent dates. In Irish pre-standing crosses also many examples in support of the theory were to be found, and the lecturer was of opinion that the “cut-out” wheel cross, which is essentially Irish, was, in its perfected form, not the result of artistic effort alone, but had gone through a process of evolution, possibly of many stages, which had for its base the symbols or designs in use long before the adoption of Christianity in Ireland.

PICTORIAL POST-CARDS.

BUSINESS has been bad, not only in our particular line, but every other, and, in fact, the first is but the corollary of the second, the average business man, being pinched, naturally cutting down expenses, and the absolutely unnecessary photograph is the first to be dropped. If one also dabbles in photographic dealing, the depression must have been more forcibly brought home to one; because the average amateur has not had the usual amount of spare cash, and he has been content with his old camera, fewer plates, and fewer chemicals this last summer, and, so far as I can see, there is not much prospect of improvement. When 12 by 10 bromide enlargements are freely advertised in the local papers for eighteenpence, and these by a local professional and dealer, who thus gets better terms than others, and the enlargements are made from any print, there is little chance for the order which but a few years ago was the customary thing with us, namely, one or two good enlargements from the negatives we took for contact prints.

I am not prepared to advance or support for one moment the statement that the pictorial or picture post-card is going to be the saviour of a business, but I can say that it will lead to the business of an extremely profitable character if properly pushed, and one that does not need much brain, supervision, or outlay. I am not going to teach others their business; I am not arrogant enough to assume that I know so much better than they do, but I can merely retail my experience, and possibly others may learn from it.

Some two years ago a local stationer brought me some post-cards of local views, and asked me whether I could not turn out something of the same sort, only of better quality, for which he could get a better price, and which could be his, and his alone. The cards, when examined, I found to be collotype printed in Saxony, and neither superb in quality as collotype nor the most striking in selection of the subjects. Having a good collection of local views, and knowing those which sold best, I promptly set to work and reduced a complete set of one dozen whole-plates to the regulation size, and, printing them in glossy gelatino-chloride, offered a set to my stationer friend. They were so different to what he had been selling that he hesitated not only to give me an order, but even to show them, but when I told him that he might have one set for his window and another set to sell free, he somewhat grudgingly accepted my offer. Within a week he had taken orders for over a hundred sets, and since then I have turned out an almost incredible number of picture post-cards, and it has become such an important section of my business that I have now a competent printer, whose sole business it is to superintend the post-card department, and this now includes gelatino and collodio chloride printing, bromide and gaslight cards, and quite lately a plain paper card of thin texture with rough deckle edge, which has promptly caught on. The post-card department now employs as many hands as the portraiture and outdoor department, and it is, if not quite so profitable, at least a big help.

I may be a present example of the old adage of teaching my grandmother to suck eggs; but, having gone through the mill till the printing of a picture post-card has become purely mechanical, some few hints of how we work may be useful. In the first place, there are very few negatives which are just the correct size, or which will even allow of masking down to the correct size; any way, all my negatives require reducing, except those which have been specially taken for post-card work, and have found that reducing the negatives in the camera to positive of the regulation size, and then making a negative by contact is the most satisfactory. Of course one may have negatives ranging from half-plate to 15 by 12, and it is necessary to reduce these in the regulation size of 5½ by 3½. Obviously, if the dimension is right the other is wrong, and one must sacrifice something. First of all, I merely reduced the whole negative on to a half-plate, keeping the longer base within the 5½ in

but I soon abandoned this, and now every negative, no matter what its size is masked before reduction, so that when reduced the best picture is shown.

For masking I use the black paper as is used by film manufacturers for rolling up with cartridge films. I was able to get some of this from a film-maker whose cartridges I stock. This is absolutely opaque, and gives one a perfectly clear rebate that saves a lot of trouble. This, cut to the necessary width, was temporarily fastened with a touch of gum to the film side of the negative, and so adjusted that when one dimension was correct the other would be also. I use always 'half-plates' for making the reduced transparency, and use a slow or ordinary negative emulsion, and not a transparency. The plates are all backed, and this is very important, and the character of the transparency is kept as nearly like a negative as possible; extreme density and absolute bare glass are avoided. A non-staining developer, adurol, in fact, is used, and, time development being adopted, a whole series of transparencies are obtained of absolutely uniform density.

The actual negatives are made by contact printing, after each transparency has been most carefully examined for spots, etc., and carefully retouched. In order to get clean, sharp edges, the negatives are again masked with lantern-slide binding strips on the film side. At first I had some difficulty about the titling, and each one was titled by painting on with a brush, but this was not very successful; sometimes the title showed clear, and others quite indistinct, according to the density of the negative. When in London one day I saw a German card in which the title was beautifully printed, and showed clear white on a perfectly black ground, and I promptly bought several, and, after consideration, I came to the conclusion that the negative was here bleached, or any deposit dissolved away, and the title printed on either directly or by transfer. Several experiments were at once carried out, and I found that cutting extremely narrow strips of hard fluffless blotting-paper of the required width, and soaking them in a saturated solution of potassium cyanide in water, mixed with an equal quantity of glycerine, gave the best results when applied to the dry negative. This dissolved out the silver, and when washed left a clear strip on which the title was very distinct.

The title was put in by means of transfer, and whilst I am not anxious to give anyone a free advertisement, I found Richard's rubber type the best. The title was set up from one of these founts, and an impression taken on the special paper supplied, which is, I believe, merely a gelatine coated paper, and the narrow strip of the negative having been gently rubbed with finely-powdered resin, the title was laid down and rubbed into contact with an old agate point that was found handy, though a bit of smooth wood would act as well, then the paper is removed and a mixture of lamp-black and dragon's blood, intimately ground together, was dusted on, and then dusted off, with the result that the letters stood out perfectly clear and absolutely opaque. No doubt others have other methods, but this satisfies me.

The ordinary post-card at the present time measures $5\frac{1}{2}$ by $3\frac{1}{2}$; and whilst some pictorial post-cards that I see have a space on the back for writing, I have found that it is quite enough to leave the front only for this purpose, and to mask the negative down so as to fill the whole of the back. Opinions, of course, will differ on this point; but I always leave one-eighth of an inch at the top and two sides, and one-quarter of an inch at the bottom of the picture, which bottom is obviously either the longer or shorter side.

I have fairly rung the changes on all the commercial cards, and have found that keeping one particular series to one particular printing process is a mistake, for the post-card enthusiast is prepared to purchase duplicates of the same card in various colours and surfaces.

I have tried P.O.P. cards, matt., and glossy, collodio chloride cards of both kinds, plain paper cards, and all colours, but I

have not yet been able to get a ferro-prussiate card which would be useful sometimes. At the present time I am pushing the plain paper card with deckle edge, for the simple reason that I can obtain any colour from bright red to black by faintly printing and development. The ordinary post-card is difficult to treat in this way, because it is so difficult to wash out the whole of the developer, so that when one comes to tone, the gold is reduced, and the card turns a faint purple tone all over. Bromide cards are, of course, mere child's play; one has merely to find the exposure, and from actual working data two operators can turn out one hundred cards per hour, exposed, developed, and fixed.

Using negatives on half-plates, whole-plate printing frames, with a sheet of glass in, are used, and the negatives are fastened down with half-inch rubber plasters, and then an accurately-cut frame of six-sheet Bristol board is fastened down in the same way, so that all the operator has to do is to drop the post-card into the aperture of the Bristol board, and it is exactly in position to print properly. These little points seem trivial; but whilst they may be, and take some little time in adjustment, a negative properly masked with its card-frame can be handed to the printer with the definite order for a certain number of post-cards in a certain process, and the order is almost automatically executed.

There may be nothing new in the above notes, but they are the outcome of experience, and may be helpful to some of my brother professionals.

T. C. GRAYDON.

STUDIO EMPLOYERS AND THE PHOTOGRAPHIC EMPLOYEES' ASSOCIATION OF N.S.W.

INDUSTRIAL AGREEMENT.

THE following, which we extract from the "Australian Photographic Journal," will, we think, be read with interest in England:—

Agreement made the seventh day of October, one thousand nine hundred and four, between Charles Henry Kerry, trading as Kerry and Co., Photographers, George Street, Sydney, hereinafter called Kerry and Co., of the one part, and the Photographic Employees' Association of New South Wales, Industrial Union of Employees, a Union registered under the provisions of the Industrial Arbitration Act of 1901 (hereinafter called the Employees' Union), of the other part.

Whereas the said Kerry and Co., and the General Committee of Management of the said Employees' Union have lately met in conference and agreed on certain matters affecting the industry or trade of a photographer, and for the purpose of carrying the said agreement into effect, it has been further agreed that these presents shall be executed and filed as an Industrial Agreement under the provisions of the above-mentioned Act.

Now these presents witness and it is hereby mutually agreed by and between the said parties hereto as follows:—

Classifications and Definitions.—(1) Any person whatsoever shall—under this log—be deemed a photographic employee who is engaged in any photographic work, namely, developing, operating (outdoor or indoor), retouching, printing, enlarging, finishing, trimming, mounting, spotting, burnishing, enamelling, sorting, or making up orders, attending to negatives in any way, working up in black and white, monochrome, or colour. (2) Employees shall be classified as follows:—Probationers, Apprentices, Junior and Seniors. (a) Probationers shall mean any person who, with a view to legal apprenticeship, shall enter the photographic profession. (b) Apprentice shall mean any person legally indentured. (c) All apprentices shall, after or without a probationary employment of not exceeding one (1) month in finishing department and three (3) months in any other department, be legally indentured. (d) Junior shall mean any persons who have served their apprenticeship. (e) Senior shall mean any person who has served his apprenticeship and juniorship, or has attained seniority, as provided by the following Clause:—(f) All assistants who prior to the enactment of this log have not attained their seniority shall in relationship to their previous term of service be rated thereunder; but when the term of service has been less than that herein-after provided shall complete the said term as indentured apprentices

or juniors in accordance with the provisions herein set forth. Nevertheless all assistants who by virtue of their value, have previously attained junior's or senior's wages shall be rated under this log according to wages previously received.

Apprentices.—(1) The term of apprenticeship for mounting, finishing, and spotting, including care of negatives, shall be two (2) years. (2) The term of apprenticeship for retouching negatives shall be three (3) years. (3) The term of apprenticeship for operating, developing, retouching, printing, and enlarging shall be five (5) years. (4) A clause in apprentices' indentures shall state specifically department or departments (and branches therein) in which apprentices shall serve and be instructed. (5) A copy of the indentures of each apprentice must be lodged with the Secretary of the Employees' Association within three (3) months of the date of the signing thereof.

Juniors.—(1) The term of juniorship shall be two (2) years in finishing and retouching departments and three (3) years in general photography.

Proportion of Apprentices and Juniors.—(1) Only one (1) apprentice and one (1) junior shall be allowed to each senior assistant employed, such apprentices and juniors to be distributed in departments as terms of indentures or necessities of business may require.

Wages.—Finishing and Reception Room: Apprentices, first year, 5s. per week; second year, 10s. Juniors, first year, 15s. per week; second year, 20s. Seniors' Minimum Wage, 25s. per week. Retouching Negatives: Apprentices, first year, 5s. per week; second year, 10s.; third year, 20s. Juniors, first year, 30s. per week; second year, 40s. Seniors' Minimum Wage, 50s. General Photography—Operating, Printing, Enlarging, and Developing: Apprentices, first year, 5s. per week; second year, 10s.; third year, 15s.; fourth year, 20s.; fifth year, 25s. Juniors, first year, 30s. per week; second year, 40s.; third year, 50s. Seniors' Minimum Wages, 60s. per week. Artists—Working up in Black and White, Monochrome or Colour: Minimum Wage, 50s. per week. Operator: Senior Minimum Wage, 70s. per week. (1) Any one employed as manager, or any one employed as head of department or branch, and having under his or her supervision at least one senior, shall, in every case, receive an advance on minimum wage of not less than 20 per cent. in finishing room and reception room and 30 per cent. in other departments, or any retoucher having two or more employees under his or her supervision shall receive a 30 per cent. increase on the senior minimum wage. (2) Any old, infirm or partly incapacitated member of the Association may be employed at a rate subject to the approval of the Committee of Management of the Association. (3) No senior shall rank as junior and be employed at junior's wages. (4) This rate of wages applies to a week of six days excluding Sundays. (5) All temporary employment of less than one week shall be paid 25 per cent. in advance on these rates.

Payment of Overtime.—(1) All work after 6 p.m. shall be paid for as overtime at the rate of time and half up to 10 p.m., after 10 p.m. double time. Sunday work, double time.

Hours. Reception Room: 8.30 a.m. to 6 p.m., October 1 to March 31; 8.30 a.m. to 1 p.m., weekly half-holiday; 8.30 a.m. to 5 p.m., April 1 to September 30; 8.30 a.m. to 1 p.m., weekly half-holiday. Retouchers and Artists: 9 a.m. to 5.30 p.m., October 1 to March 31; 9 a.m. to 1 p.m., weekly half-holiday; 8.30 a.m. to 5 p.m., April 1 to September 30; 8.30 a.m. to 1 p.m., weekly half-holiday. Operators: 9 a.m. to 5.30 p.m., October 1 to March 31; 9 a.m. to 1 p.m., weekly half-holiday; 9 a.m. to 5 p.m., April 1 to September 30; 9 a.m. to 1 p.m., weekly half-holiday. Printing Room, Contact Printers, Enlargers, Finishing Room, Dark-Room Hands, and Apprentices: 8.30 a.m. to 5.30 p.m., October 1 to March 31; 8.30 a.m. to 1 p.m., weekly half-holiday; 8.30 a.m. to 5 p.m., April 1 to September 30; 8.30 a.m. to 1 p.m., weekly half-holiday.

Lunch.—Three-quarters of an hour shall be allowed for lunch in every case, except to operators, who shall have 30 minutes in winter (April 1 to September 30) and 45 minutes in summer (October 1 to March 31).

Holidays.—(1) All employees shall have one half-holiday per week. (2) The following days shall be public holidays within the meaning of this Log:—New Year's Day, Anniversary Day, Good Friday, Easter Monday, Prince of Wales' Birthday, Eight Hour Day, King's Birthday, Christmas Day and Boxing Day, and shall be paid for at full rates. (3) Any employee working on a public holiday shall have

one day off within 7 days in lieu thereof. (4) Every employee, after working 2 years consecutively in the same establishment, shall be entitled to one week's holiday annually on full pay.

Piece Work.—Retouching Panels: Evening dress, bust head, 2s. extra figure, 1s. Ordinary dress, bust head, 1s. 6d.; extra figure, 1s. Evening dress, three-quarter figure, 1s. 6d.; extra figure, 6d. Ordinary dress, three-quarter figure, 1s.; extra figure, 6d. Evening dress, full length, 9d.; extra figure, 6d. Ordinary dress, full length, 6d.; extra figure, 6d. Cabinets: Evening dress, bust head, 1s. 3d.; extra figure, 6d. Ordinary dress, bust head, 1s.; extra figure, 6d. Evening dress, three-quarter figure, 9d.; extra figure, 4d. Ordinary dress, three-quarter figure, 6d.; extra figure, 4d. Half-price each additional head. Full length, 4s. per dozen all round. Babies' nude panels, 1s. 6d. each; cabinets, 1s. each. Midgets; 10 midgets, on whole plate, 2s. per plate; 4 York panels, on whole plate, 2s. per plate; 2, 3, 4, or 8, on cabinet plate, 1s. per plate. Groups—Studio or Outdoor: Whole plate, 2s. 6d.; 10 x 8, 3s. 6d.; 12 x 10, 4s.; 15 x 12, 6s. Printing and Enlarging: Baker and Rouse's quotation nett, in 1904 catalogue. Working up Enlargements. — Monochrome or Black and White: 10 x 8, 4s.; 1s. 6d. extra each figure; 12 x 10, 4s.; 1s. 6d. extra each figure; 15 x 12, 5s.; 1s. 6d. extra each figure; 17 x 23, 10s.; 1s. 6d. extra each figure. Oil or Water Colour: 10 x 8, 7s. 6d.; 12 x 10, 7s. 6d.; 15 x 12, 10s.

General.—(1) Seven (7) days' clear notice shall be given on both sides for termination of engagement. (2) A book shall be kept in each establishment showing wages paid to each employee. (3) Each establishment shall be registered and a return furnished to the Registrar of the hands employed therein and the wages paid thereto, classified in accordance with the provisions of the Shop and Factories Act. (4) The Secretary of this Association shall have the power to inspect time-books and wagesheets, and in the case of any dispute arising as to the ratio of apprentices and juniors to each senior hand in any establishment to have the right to count the number of apprentices and juniors as well as the said seniors at any time during working hours. (5) The Association shall be allowed to appoint stewards in any establishment to facilitate the collection of contributions. (6) Members of this Association shall receive preference of employment, all things being equal. (7) Subsequent to the enactment of this log every non-member employed in any establishment shall become members of this Association within one month. (8) This agreement, and every clause, matter, and thing herein contained shall (subject to the provisions of the said Act as to the rescinding or varying the same) remain in full force and effect for a period of three years from the first day of November next. (9) The said Employees' Union shall at once apply to the Court of Arbitration that this agreement may be declared to be the award of the Court, and a common rule of the trade as against all masters, photographers, and employers carrying on business in the State of New South Wales. (10) That either the said Kerry and Co., or Employees' Union breaking this agreement or any term thereof, is liable to a penalty not exceeding £100 (one hundred pounds), and individual members thereof committing a breach are liable to a penalty not exceeding £5 (five pounds).

In witness whereof the signatures and seals of the parties hereto have been hereto affixed the day and year first before written.

Signed by the said Kerry and Co., in the presence of the General Committee of Management of the said Union.

The Common Seal of the Photographic Employees' Association Industrial Union of Employees was hereto affixed by the General Committee of Management of such Union in the presence of

JAMES CHARLES CRUDEN, President,
THOMAS CHARLES CLEAVE,
FREDERICK JOHN JENKINS,
ALBERT HATTON,
WALTER R. SMITH,
HAROLD BRADLEY,
ANDREW MORRISON,
JOHN STEWART, Jun.,
WALTER DAVIES, Secretary,

Members of the
General Committee
of Management.

Received into the Industrial Arbitration Office, at Sydney, this twelfth day of October, 1904, at fifteen minutes past two of the clock in the afternoon, from Walter Davies, of Wemyss Street, Stanmore, photographer, a true copy of the within industrial agreement, veri-

by the oath of the said Walter Davies, and now numbered forty-one (41).

E. W. WICKHAM,
For Registrar, Industrial Arbitration Act.

Exhibitions.

THE HOVE CAMERA CLUB.

The club held their exhibition last week. This was the first of the South Coast exhibitions—Hove, Southsea, and Southampton—which are being carried on with the same arrangements as in previous years. The judges were E. R. Ashton, H. Horsley Hinton, and C. Job, and the average work in the open classes was of such high quality that they had no hesitation in awarding all the thirteen prizes placed at their disposal.

The following is a complete list of the awards:—

OPEN CLASSES.

Class A.—Landscape: Plaque, "Reflections," W. A. I. Hensler; plaque, "Shadows," A. Marshall; plaque, "Desolation," J. M. Whitehead; plaque, "The Vesper Hour," B. C. Wickison; hon. mention, "The far off sun darts his slant beams on unobeying clouds," H. A. Game; hon. mention, "Threshing Thro' It," F. R. D. Croogss.

Class B.—Portraiture: Plaque, "The Student," A. Marshall; plaque, "The Modeller," C. B. Howdill; plaque, "Waiting," R. Forbes; hon. mention, "May," Miss Hilda Stevenson.

Class C.—Architecture: Plaque, "St. Mark's, Venice," F. J. Phillips; hon. mention, "Kirkstall Abbey, across the Nave," John Mackenzie; hon. mention, "A Flood of Light," W. A. Clark.

Class D.—Flowers, Animal Studies, etc.: Plaque, "A Marten," Douglas English, F.R.P.S.; plaque, "Nettles," G. Seymour; hon. mention, "Peonies," D. W. Kyle; hon. mention, "A Rose," Miss M. C. Eames.

Class E.—Lantern Slides: Plaque, "On the Hillside," W. A. I. Hensler; plaque, "Roses," R. Burnie; plaque, "Male Reed Warbler," W. Farren; hon. mention, "Figure Studies at Night," Ellis Kelsey; hon. mention, "Architecture," H. Wormleighton; hon. mention, "Theatrical Groups taken during Performance," E. F. Grün.

CLUB CLASSES.

Challenge Salver, for Best Picture in Club Classes (Presented by W. A. Hounsom, J.P.): "A Portrait," Mrs. A. O. Jennings. (Note.—Mrs. Jennings now becomes the absolute owner of this salver, having won it three times during the last six consecutive years.)

Class J.—Landscape: Plaque, "A Sandy Track," F. J. Phillips; plaque, "Evening Mists and Mountain Torrents," W. White Palmer; hon. mention, "Homeward by the Evening Light," A. H. Avery; hon. mention, "In the Valley," V. G. Young.

Class K.—Portraiture and Animal Studies: Plaque, "A Portrait," Mrs. A. O. Jennings; plaque, "Figure Study at Venice," Miss M. Cotesworth; hon. mention, "Shrimpers," L. J. Steele; hon. mention, "A Marten," Douglas English, F.R.P.S.

Class L.—Architecture: Plaque, "Winter Sunshine," C. C. Cook; plaque, "The Sanctuary Temple of Luxor," L. J. Steele; hon. mention, "South Aisle, Chichester," V. E. Morris; hon. mention, "Cottages at Rye," F. R. Richardson.

Class M.—Lantern Slides: Plaque, "Across the Nave, Chichester," V. E. Morris; plaque, "Evening Mists and Mountain Torrents," W. White Palmer; hon. mention, "Theatrical Groups," E. F. Grün; hon. mention, "Figure Studies," Col. Crawley.

Class N.—Novices: Plaque, Miss M. Reeves; hon. mention, H. N. Kinton.

SHEFFIELD.

The Sheffield Photographic Society's annual exhibition of photographs was held at the Montgomery Hall, Sheffield, from November 21 to 26. The judges (Messrs. C. Barrow Keene, Alex. Keighley, and Frank M. Sutcliffe) made the following awards:

OPEN CLASSES.

A.—Champion Class: Silver gilt plaque, "In Pensive Mood," John Spark.

B.—Landscape, Seascape, and River Scenery: Silver plaque, "Shadows," A. Marshall, A.R.I.B.A.; bronze plaque, "Britain's Bulwarks," Chas E. Wanless; Extra bronze plaque, "Desolation," J. M. Whitehead; certificates, "Woodlands," Arthur Black; "A Seat of Industry," Will H. Foxall; "Close of an Autumn Day," Daniel M. Filshill.

C.—Portraiture, Figure Studies, and Animals: Silver plaque, "The Modeller," Chas. P. Howdill, A.R.I.B.A.; bronze plaque, "A Study," A. Marshall, A.R.I.B.A.; certificates, "A Countenance in which did meet Sweet records, promises as sweet," John Spark; "A Cornish Fisherman," Dr. C. F. Grindrod.

D.—Architecture, Interior or Exterior: Silver plaque, "The Close of a Summer's Day," Wm. A. Clark; bronze plaque, "The Marble Arch," Miss A. B. Warburg; certificates, "A Street of the Past," C. C. Cook; "Torcello Cathedral," A. De Silva.

E.—Flowers, Fruit, and Still Life: Silver plaque, "Decorative Study of Tulips," John M. Whitehead; extra silver plaque, "Briar Roses," John M. Whitehead (debarred); bronze plaque, "Currants," E. Seymour; certificate, "Poppies," Dan Dunlop.

F.—Lantern Slides: Silver plaque, "Reed Warbler," Wm. Farren; bronze plaque, "A Woodland Glade," J. W. Charlesworth; extra bronze plaque, "Emperor Moth (male)," B. H. Bentley; certificates, "Wood Anemones," B. H. Bentley (debarred); "Fusus Colus," Dr. G. H. Rodman; "Lightning Flash," John Stabb.

SPECIAL CLASSES.

G.—For Members of Photographic Societies in Yorkshire: Silver plaque, withheld; bronze plaque, "An Olde Doorway," W. Wadsworth; certificate, "Conway," Miss F. Ashton.

H.—For Scholars attending any Day School within the City of Sheffield: Silver plaque, "The After Glow," Tom Robertson; bronze plaque, "In Whiteley Woods," W. Warner; certificate, "The Old Abbey Stairway," Harper Seed.

MEMBERS' CLASSES.

I.—Landscape, Seascape, and River Scenery: Silver plaque, "The Dell," J. Gilbert Jackson; bronze plaque, "September," Dr. H. G. Paterson; certificate, "On the Sand Dunes," Harold Hill.

J.—Architecture, Interior or Exterior: Silver plaque, "Through an Open Doorway," Harold Hill; bronze plaque, "From Transept to Nave, Ely," John W. Barnes; certificate, "Corner of Banqueting Hall, Haddon Hall," T. G. Hibbert.

K.—Any Other Subject: Silver plaque, "The Pearl Sorter," Dr. H. G. Paterson; bronze plaque, "Lightning," F. J. Cribb; extra bronze plaque, "Study of a Head," Hy. S. Nutt; certificate, "Peeling Potatoes," John W. Barnes.

L.—Lantern Slides: Silver plaque, "The Halut of the Moorhen," W. H. Barraclough; bronze plaque, "Chapter House, Lacock Abbey," J. R. Wigfull, A.R.I.B.A.; extra bronze plaque, "The Sturdy Oak," Dr. H. G. Paterson; certificates, "Through the Doorway, Haddon," T. G. Hibbert; "Near Wadley," G. A. Seed.

ILFORD AND DISTRICT PHOTOGRAPHIC SOCIETY.

The following were the awards made by the judges (Messrs. J. T. Ashby, F.R.P.S., and Furley Lewis), and it was held last week:—

OPEN CLASS.

Gold medal, "The Vesper Hour," B. C. Wickison; silver medal, "The Soothing Weed," E. H. R. Hillsworth; silver medal, "Cobbling," W. Pickering; bronze medal, "Currants," E. Seymour; bronze medal, "From Transept to Nave," S. G. Kimber.

MEMBERS' CLASSES.

Class 1.—Silver Medal, "Sunshine and Shadow," D. S. Whitelaw; bronze medal, "Sunshine in the Forest," H. R. Hill; highly commended, "Nature's Wealth," D. S. Whitelaw; highly commended, "After a Shower," C. G. Jones; commended, "In October," D. S. Whitelaw; commended, "On a Cornish Moor," H. R. Hill.

Class 2.—Silver medal, "Entrance to Choir, Rochester," C. G. Jones; bronze medal, "At Rochester Cathedral," A. Frost; highly commended, "A Norman Relic," D. S. Whitelaw; commended, "The Font, Rainham," H. Gulliver.

Class 3.—Silver medal, "Rhododendrons," E. W. Perrett; bronze medal, "Breakfast," H. Cole; commended, "John Bull," H. Cole.

Class 4.—Beginners: bronze medal, "Choir Screen, Rochester," H. C. Frost.

Class 5.—Lantern Slides: silver medal, "Margate Lifeboat," A. R. Mann; commended, "Southampton Water," W. N. Beal.

Class 6.—Hand Camera Work: silver medal, "Off to the Fishing Grounds," D. S. Whitelaw.

We are glad to hear that the exhibition was such a success that it was found necessary to keep it open for another day.

GLASGOW.

THERE was a very large collection of pictures at the annual exhibition of the Glasgow Eastern Amateur Photographic Association, opened last week in the Club rooms, Landressy Street, Bridgeton. The judges of the relative merits of the exhibits were Messrs. Wm. Crooke and Archibald Cochrane, who made awards as follows:—

MEMBERS' CLASSES.

1. Any subject: silver plaque, W. S. Crocket; bronze, M. Crosbie; certificates, John Brough and M. Wilson.
2. Portraiture: bronze plaque, G. R. Johnstone; certificates, Alex. Gault and W. S. Crocket.
3. Club outings: silver plaque, John Brough; bronze, M. Crosbie; certificate, W. S. Crocket.
4. Novices: silver plaque, J. G. S. Sproul; bronze, James Bicker; certificate, Jas. Watson.
5. Lantern slides: silver plaque, W. S. Crocket; bronze, Andrew Walker.

The special prize for the best picture in the above five classes was awarded to Mr. W. S. Crocket's picture, "Twixt Spring and Summer," a charming little woodland scene.

OPEN CLASSES.

6. Any subject (open to Federation Associates only): bronze plaques, A. W. Hill, M. Warnock, and W. Milroy.
7. Any subject (open to all): silver plaques, R. Forbes and A. Allan; bronze, S. G. Kimber and J. A. Angus; certificates, E. J. Jarvis and J. S. Andrew.
8. Lantern slides (open to all): silver plaque, R. Ure; bronze, F. G. Tryhorn; certificates, John Hobbs and G. A. Booth.

IPSWICH.

THE Ipswich Camera Club's first annual exhibit was opened on the 22nd ult. Award list:—

Section A (Open).—Class I.—Landscape, etc.: Silver medal, Mr. T. Jackson; bronze ditto, Mr. W. Clayden; gold medal for best picture in exhibition, Mr. T. Jackson. Class II.—Figure Studies and Animals: Silver medal, Mr. S. Foster; bronze ditto, Mr. G. Johnson. Class III.—Architecture: Silver medal, Mr. W. A. Clark; bronze ditto, Mr. A. E. Wiggins. Class IV.—Lantern Slides: Silver medal, "Sunshine and Shadow," Mr. H. Wormleighton; bronze ditto, "Childhood's Joys," Mr. Graystone Bird.

Section B (Members' Classes).—Division I.—Class I.—Enlargements.—Landscape, etc.: Silver medal, Mr. P. W. Elkington; bronze ditto, Mr. R. H. Sutton; h.c., Mr. R. H. Sutton and Mr. A. Leathers; silver medal for the best picture in the Members' Section, Mr. P. W. Elkington. Class II.—Architecture: Silver medal, Dr. Francis Ward; bronze ditto, Mr. A. J. Leighton. Division II.—Class I.—Landscape: Silver medal, Dr. J. Hossack; bronze ditto, Rev. N. J. Raper; h.c., Mr. R. H. Sutton. Class II.—Seascape and River Scenery: Silver medal, Mr. P. W. Elkington; bronze ditto, Rev. N. J. Raper and Mr. R. Dixey; h.c., Mr. R. H. Sutton. Class III.—Architecture: Silver medal, Mr. R. H. Sutton; bronze ditto, Mr. E. Braddell; h.c., Mr. E. Braddell. Class IV.—Figure Studies and Animals: Silver medal, Miss M. L. Steward; bronze ditto, Mr. E. Fry; h.c., Mr. R. H. Sutton. Class V.—Flowers and Still Life: Silver medal and h.c., Dr. Francis Ward.

In Section C, not for competition, several beautiful enlargements are kindly exhibited by Mr. A. B. Corder, Mr. F. W. Goffin, Mr. A. F. Penraven, Mr. J. Fenn Cole, Mr. B. Harris, and thirty pictures sent by the Royal Photographic Society.

BRAINTREE.

THE second annual exhibition of the Braintree and Bocking Camera Club took place Thursday week. A very creditable show was made, especially in the local classes, which were a decided improvement on last year. Altogether there were over 250 pictures on view, the prizes being fifteen silver and bronze medals, which were given by the president (Mr. E. B. Knobel, M.R.P.S.). Artistically-prepared diplomas were also awarded for creditable exhibits. Awards:—

Open Classes.—Landscape, River Scenery, and Marine: Silver

medal, "A Sussex Village," H. C. Bird; bronze medal, "Old and Twisted," E. B. Wain; diploma, "A Gleam of Light Duplicates," W. Clayden. Portraiture and Figure Studies: 1st, "Sea Urchins," S. J. Steele; 2nd, "An Ancient Mariner," W. H. Foxall; 3rd, "The Student," Architecture: 1st, "The Crypt, Winchester," T. Weaver; 2nd, "Transept to Nave," S. G. Kimber; 3rd, "A Norman Procession," Flowers, Still Life, and Animal Studies: 1st, "Chrysanthemums," E. Seymour; 2nd, "Daffodils," F. W. Beken; 3rd, "Geranium," A. W. Walburn. Set of Four Lantern Slides: 1st, bronze medal, W. H. Guy; 2nd, diploma, J. E. Tyler.

Club Classes.—Landscape, etc.: Bronze medal, "Pines," E. Malvern; diploma, "Ventnor," H. T. Lawson; h.c., "Silver Birches," H. Cole, and "Through the Avenue," the Rev. A. Curtis. Portraiture, etc.: 1st, "Breakfast," H. Cole; 2nd, "Age," H. Cole; 3rd, "A Portrait" (Mr. S. C. Parmenter), W. H. Tilston. Architecture: 1st, "Norwich Cathedral," H. Cole; 2nd and medal, "Old Lucerne," the Rev. A. Curtis; 3rd, "Where Time Moves Slowly," W. H. Tilston; h.c., "Breton Church," H. S. Tabor. Still Life and Animal Studies: 1st, "Chrysanthemums," H. Cole; 2nd and medal, "Animals," J. E. Tyler; 3rd, "Perfect Twins," F. Hayward. Lantern Slides: 1st, H. G. Lawson; 2nd, C. A. Carter; 3rd, J. E. Tyler. Snapshots: 1st, "Outward Bound," E. E. Malvern; 2nd, "A Street Scene," E. E. Malvern; 3rd, medal, "Uphill," H. Wardlaw Fuller; h.c., "With Wind and Tide," H. S. Tabor; "The Starter," Mrs. J. Johnson.

FORTHCOMING EXHIBITIONS.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-10 West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, G. Kimber, Oakdene, Highfield, Southampton.

December 23-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 133, Glasgow Road, Wishaw.

January 12-14, 1905. Boston Camera Club. Hon. Sec., H. J. Hames, 65, West Street, Boston.

January 14-23, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Michell, 180, Browning Road, Manor Road, E.

January 23-February 12, 1905.—Photographic Society of Marseille. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 25-March 4, 1905.—Birmingham Photographic Society. Hon. Sec., Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11, 1905.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14, 1905.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Cliden Road, Brentford.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Sec. John B. Parnham.

June, 1905.—Northern Photographic Exhibition. Secretary, F. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

December 31.—Barnet. Nineteen classes. Prizes valued at 25s for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

CHLORO-BROMIDE OR GASLIGHT PAPERS.

[Abstract of a communication to the International Union of Photography.]

The photographic print is the end, the negative but the means. We ought then to look upon all photographic operations as conducive to the obtaining of a perfect print, and we ought not, as so many do, to stop short when we have obtained a good negative.

The number of processes by means of which we can obtain a print are to-day very numerous, and some are more or less artistic and others more or less convenient. Let us then examine them with this in view.

Albumen paper certainly gives us permanent prints, but its printing is long and the manipulation complicated. Turning to the papers with gelatine and collodion surfaces, they are rather more rapid than the last and more convenient to manipulate; but this convenience of manipulation results in a very ephemeral stability inferior to that of albumenised paper. Moreover, the effect of gelatino and collodion prints, with their glossy surfaces, leaves much to be desired from an artistic standpoint. If these papers continue to be used by amateurs it must be put down to conservatism and habit. One cannot praise their simplicity of manipulation, for it is not more difficult to obtain a print by development than by printing out.

The process of printing on bromide paper is a big step in advance of printing out. The prints obtained are very permanent, if they are properly washed; printing is rapid, for one is not dependent on the caprices of the light, and instead of in the dull days having to wait for days for a complete print, it can be made in a few seconds. The manipulation is not more difficult than printing out, and the deep blacks and pure whites give the print a very pleasing effect, resembling that of an engraving.

There are certain inconveniences in bromide printing, as, for instance, it must be worked in a red light, and it is therefore difficult to see the correct moment at which to stop development. The exposure, too, must be very exact, for if the print be under or over-exposed the chances are that it will be useless; then again the black colour, which cannot be varied, is not suitable for all subjects.

Another kind of development paper is the chloro-bromide, and this possesses some advantages over bromide paper.

Chloro-bromide paper is one in which the image is latent, and the development is formed by a mixture of chloride and bromide of silver. Although so much slower than bromide paper, it can be exposed to artificial light, although daylight can be used, but it is not advisable, as daylight is so variable.

The diminished sensitiveness constitutes one of the great advantages of this paper, as it is possible to manipulate by white artificial light and the red lamp is dispensed with. This advantage is of great importance to the numbers of amateurs who have not a spacious dark room, and the paper may be printed and manipulated at about a yard from an open gas flame.

For a normal negative the exposure is from one to ten seconds to diffused daylight, two yards from a window, ten to fifteen minutes at about ten inches from a petroleum lamp, eight to twelve minutes to a kerosene gas burner, and from seven to ten minutes to a 16 candle power electric light, and about one inch of magnesium ribbon at about eighteen inches, and from half to one and a half minutes to an incandescent gas burner. Magnesium is the most satisfactory light, its cost is little, and the exposure so short. Of course, the exposure varies with the density of the negative, but it may be varied by altering the distance between negative and light or burning a longer or shorter piece of ribbon.

Unlike bromide paper, the exposure here need not be exact, and chloro-bromide paper has the useful property of giving a variation of tone with the variation in exposure. The scale starts with greenish-black, passing through black, warm black, brown, sepia, and blood-red to yellow; the shorter the exposure and the more energetic the developer the more the tone tends towards black. The table given below gives the various tones obtained with different exposures and different strengths of developer, but if the tone is not that which was desired the print is by no means useless.

Now, to obtain with certainty the desired tone the exact exposure required to give black tones should be found by trial and error, and when it is only necessary to alter the time of exposure and the developer according to the table.

The developers for these papers should always contain potassium bromide, the absence of which causes fog. This is possibly the cause

of the non-success of some amateurs with this class of paper. The best developers are hydroquinone and edinol, the others do not enable such a variety of tones to be obtained. For hydroquinone the following should be used:—

A.

Boiled water	1,000 c.c.
Sodium sulphite (cryst.)	125 g.
Hydroquinone	15 g.
Sodium carbonate (cryst.)	250 g.
Potassium bromide	10 g.

And for edinol—

Water	1,000 c.c.
Acetone sulphite (Bayer)	50 g.
Edinol	10 g.
Sodium carbonate (cryst.)	35 g.

Tone of the dry print.	Exposure.	Hydro. devel. A to be diluted with	Edinol to be diluted with
Blue black	Normal ..	undiluted ..	8 parts water + 0.3 potass. carb.
Green black ...	Normal ..	5 parts water	9 parts water.
Olive green ...	Twice normal	5 " "	
Sepia ...	Three times normal	10 " "	
Brown ...	Four times normal	10 " "	9 parts water + 0.3 parts conc. sol. of acetone sulphite or 0.15 dry acetone sulphite.
Red brown ...	Six times normal	20 " "	
Yellow brown	Eight times normal	20 " "	
Blood red ...	Nine times normal	30 " "	50 parts water + dry acetone sulphite 0.5 parts.
Red orange ...	Ten times normal	30 " "	
Yellow ...	Twenty times normal	40 " "	

By adopting this method of working identical results are obtainable every time with the greatest ease.

LEOPOLD LÖBEL.

THE DEVELOPMENT WITH AN ACID DEVELOPER.

M. MAES, the Editor of the "Journal de Photographie Pratique," points out in a recent number that having experimented with the method proposed by M. Balagny of using amidol with an acid bisulphite solution, he was led on to try other developers in similar fashion with excellent results, and possibly the following abstract of his notes may be of interest.

For some considerable time it has been obvious that photographers had gradually been led on to use far too much alkali in their developers as a rule, and that though more time was needed, yet finer results were obtainable by using an acid developer. Strongly alkaline developers not only tend to fog the plates, but also give one no time to correct errors in exposure.

The formula actually used is as follows:—

Rain water, filtered ...	1000 cc.	1 oz.
Sodium sulphite (anhydrous) ...	20 g.	10 grs.
Potassium carbonate (anhydrous) ...	8 g.	4 grs.
Pyrogallol acid ...	8 g.	4 grs.
Potassium bromide (10 per cent sol.)	48 dps	24 dps.
Glacial acetic acid ...	48 dps	24 dps.

The equivalent English measures are given against the metric, or rather, the same ratio, practically, per ounce of solution.

The development with this solution is slow; the image appears in about two minutes, and the total time of development is from ten to twenty minutes. Thus slowed, the development does not give those disadvantages which are always the accompaniment of strongly alkaline developers, such as excessive densities, fog and other known defects. On the contrary, the negative presents a fineness and a gradation which is comparable only to those obtained in the old collodion days. It is soft, full of detail, harmonious, yet vigorous without harshness. The most opaque parts yet remain permeable to light, and the half-tones and the delicate shades are completely preserved.

There is a grand margin of latitude, and there is plenty of time

to correct errors. If, for example, the image appears before one and a half minutes, one may be sure that the exposure has been too long, and two or three drops of bromide or acetic acid may be added, and this acts as a very strong restrainer. If, on the other hand, the image does not appear till after two minutes, it is a sign that the exposure was too short, and the addition of a pinch of carbonate of potash may be added.

Development with an acid possesses other properties, such, for example, as the suppression of halation to a great extent. It may be said that our formula is not actually an acid development. This is quite true. The addition of the acetic acid produces acetate of soda. This is obviously correct, but there may be other combinations formed, for a developer to which acetate of soda is added does not produce the same results.

Experiments have also been made by M. Maes of other developers with equally satisfactory results. Thus, amidol gives equally good results with bromide and chloro-bromide papers if the following formula be used:—

Water	1000 cc.	1 oz.
Sodium sulphite (anhydrous)	20 g.	10 grs.
Amidol	8 g.	4 grs.
Potassium bromide (10 per cent. sol.)	64 g.	32 grs.
Glacial acetic acid	64 g.	32 grs.

The development is less rapid than usual, but the whites remain pure and the blacks vigorous, and the tones cold.

Lantern plates give equally satisfactory results, pyro gives browns and sepias, and amidol blacks and whites. Ortol and adurol give equally satisfactory results, but pyro is the most satisfactory.

Last year Professor Valenta called attention to the use of an excessive quantity of alkali when pyro was used, as the developing agent, and proved that when just sufficient alkali was used to form a mono-phenolate of the base, a quick and clean pyro developer was obtained, which was more nearly like the rapid working developers, like metol, etc. The formula is:—

No. 1.

Sodium sulphite	80 grs.	160 g.
Pyrogallol	12½ grs.	25 g.
Water	½ oz.	500 cc.

Dissolve and make up the total bulk to 1 oz. or 1000 cc.

No. 2.

Caustic potash	5½ grs.	11.5 g.
Or caustic soda	4 grs.	8.0 g.
Water to	1 oz.	1000 cc.

For use, mix equal quantities of No. 1 and No. 2 and water.

Those who have not tried this particular formula should give it a trial, as it works quite cleanly, without any stain or tendency to fog or frilling, and gives great density with rapidity of action.

New Books.

"The Englishwoman's Year Book," 1905. Edited by Emily James and published by Adam and Charles Black, Soho Square, W.

We have been informed by certain ladies of our home circle that this is an excellent book for women, and contains all that they are ever likely to want to know, from nursing to woman's suffrage. Being, however of the opposite and less noble sex, we instinctively turned to the article on "Photography," which is included in the second section of the work devoted to employments and professions, and find there the following advice, which may be entertaining, if not useful, to our readers:—

"PHOTOGRAPHY.

"Photography as a profession offers a considerable opening to an intelligent woman with some artistic capacity. But though trained intelligence is probably the first essential to success, practical business capacity and energy are most important too. For in this, as in all other professions, the market is already overstocked, and the prizes, though large, are few. There is one serious drawback to its adoption as a business, and that is the difficulty of obtaining adequate training. The Regent Street Polytechnic advertises a 'professional course,' the fee for which is £52 10s.; but as there is no studio at the institution for the use of students, the students must, in consequence, find their own studio to practise in; the expense of such a training becomes, of course, considerable. The best way to get the requisite knowledge

and experience is probably to put up a portable studio in the back garden, which can be done for under £50, buy a shelf full of good photographic manuals, such as Wail's 'Dictionary of Photography' and the very practical little manuals on the various processes involved, published by Percy, Lund, and Company, and the work hard for a year, pressing all one's family and acquaintance into the service as sitters, and gradually getting enough paying work, as it improves in quality, to pay the necessary current expenses. But though a great deal may be done in this way, there is still much which cannot be learnt except from an experienced teacher, and no one should think of starting as a professional until they have worked for at least two or three months as a pupil in some well-known studio. In order to accomplish this would be well to fix on some really first-rate photographer in a provincial town, and then boldly write and ask if he will take a pupil. If, as we are assuming, the intention be ultimately to start in London, he will not be deterred from saying Yes by any fear of further overstocking his own market. Then when the necessary training is obtained, there is still the question of capital to be considered, and you are convinced that to start adequately in London, with a properly equipped studio, requires a sum of at least £400. But if such a sum be not forthcoming it would be much wiser for the would-be landscape photographer to give up all idea of London, and settle in some country district, where rents are cheap, and she has friends to back her, and where, if she cannot hope to rival Miss Alice Hughes, Miss Jennings, or Miss Macnaghten, she will probably be able to make enough to live upon quietly and comfortably."

"For women who undertake work for photographers at regular salaries, the average remuneration for retouching is 25s. to 40s. per week. Spotters and mounters usually earn from 15s. to 20s. per week, though an exceedingly capable woman might earn more in a good studio. For working up, salaries from 15s. to 50s., according to quality; but the profession is much overstocked."

"The Canterbury Pilgrimages." By H. Snowden Ward. Published by Adam and Charles Black, Soho Square, London, W.

Mr. Snowden Ward has now become identified with a particular class of work, in which he takes some special subject such as the life and exhausts it, and in which he is so ably seconded, as far as illustrations go, by Mrs. Ward. "Shakespeare's Town and Times" and "The Real Dickens Land" are similar and previous works by the same authors, because one must not separate man and wife. The quote from the introduction, "The interest of this book centres around two great tragedies, the fall of Thomas the Archbishop and the fall of the worship of Thomas the Martyr. These are bound up with a part of a still greater tragedy, the collapse of a grand religious movement, which, with all its human imperfections and shortcomings, had done a noble work for those who needed it most—the poor, the weak, the sorrowing."

Tracing the life of Thomas Becket through all his trials and perils, we are led up to the final causes of the catastrophe and the results that followed, and it is obvious that the information given is as reliable as it is possible for careful research and comparison of the older records to make it. The growth of the worship is described in an equally satisfactory manner, and also the tragedy of its fall, as Mr. Ward terms it.

Naturally, Geoffrey Chaucer, that most excellent chronicler in verse of the times, tales, and customs of a couple of centuries later, is largely drawn upon, and we are introduced to the several and principal characters of the pilgrimages, which had become the fashion, and each day we are led along the pilgrims' way with pleasant chat and story and excellent illustration.

We note that in dealing with that particular section of the district, Eastwell Park, a locality with which in boyish days we were so familiar, Mr. Ward suggests that what we knew as the Pilgrims' Way was but a trade road. He almost convinces us, and yet we are loath to lose one more cherished remembrance of our boyish days. Then, again, we note that the old legend as to the yaws being planted along the "Way" as way-marks, and that they were called "palms," is seriously discounted by the author, and rightly, too. The old yaws so frequently met with on the chalky downs of Kent and Sussex were undoubtedly planted to provide the necessary wood for the bow so long the weapon of the English.

The book is extremely interesting, and one gathers a very clear idea of the old times from it, and its value is much enhanced by the very large number of extremely fine illustrations provided by Mrs. Ward.

New Materials.

born Photo-Calendars and Sensitised Christmas Cards. Houghtons, Limited.

The increasing popularity of calendars as Christmas cards has led Messrs. Houghton to introduce a series of calendars mounted on cards measuring $7\frac{1}{2}$ in. by $5\frac{1}{2}$ in., provided with openings of various sizes, into which an unmounted photo can be slipped in the usual manner. The calendars are stocked in two colours, green and red.

with bevelled edges and white bevelled openings with fancy blocked design. The word "Calendar" is stamped on the tear-off portion. They can be suspended by means of the brass ring at top. The cards are supplied in shilling packets of one dozen, of four different designs, and two black paper masks. Half of the front or

the reverse side of the card is reserved for a suitable greeting, surrounded by an artistic border. At the foot of this design there is a space for the signature of the sender, while the whole of the back is coated with gaslight emulsion, on which the photographer can print one of his own pictures. The card forms at once a pleasing and dainty memorial of the festive season, and it is not likely to be thrown away as a more impersonal card.

Carbon Tissue and "Court" Postcards. The Rotary Photographic Co., Ltd.

These tissues and postcards were briefly noticed in our issue a fortnight ago; since then we have had an opportunity of using the carbon tissue, seventeen pieces of which were sent us, and of the following colours:—Pure black, engraving brown, photo brown, brown, red chalk, purple, red, dark blue, light blue, light green, dark olive, violet, sea green, transparency black, transparency sea green, warm sepia, and cold sepia. Blue, red, and yellow tissues for colour work are also supplied. The tissues are of the highest possible quality, and give us excellent results. The process of sensitising is simple, and full particulars of how to do it and many other interesting particulars for working the whole process are given in the pamphlet sent out with each packet.

The "Court" postcards are quarter-plate size, and have rounded

edges. Other sizes introduced by the Company are the ordinary size ($5\frac{1}{2}$ by $3\frac{1}{2}$), panel ($5\frac{1}{2}$ by $1\frac{1}{2}$), and midget ($2\frac{1}{2}$ by $3\frac{1}{2}$). The cards can be obtained in "Rotograph" rapid bromide and "Rotox" slow gaslight emulsions, matt and glossy. They give us excellent results; the gaslight when developed with rodinal, ferrous-oxalate, or metol-hydroquinone, and the "Rotograph" cards when the "Rotograph" special developer, iron, amidol, metol, eikonogen, or hydroquinone. All formulæ are given in each packet. We note that the Company's bromide paper is now supplied in seven grades, as follows:—(a) Thin glossy, (b) thick glossy, (c) thin matt smooth, (d) thick matt smooth, (e) thin matt rough, (f) cream tinted thick rough, (g) thick rough white.

Negative Vignettes, Masks, and Discs. Sold by Kodak, Ltd., Clerkenwell Road, E.C.

So many now use photography for the preparation of Christmas and New Year cards that this series of paper negative vignettes and masks and discs will be readily welcomed, and they act equally well with a printing-out as with a development paper, and they measure $5\frac{1}{2}$ by $3\frac{1}{2}$, so can be used for the popular picture postcard if desired. The designs are neat, and the masks of various shapes.

Cubrome. A. Edmund and Co., Ezra Buildings, Columbia Road, London, E.

Cubrome is a bleaching solution for intensifying negatives and bromide prints by the copper process, thus avoiding the use of the more poisonous mercury salts, and giving more permanent results. The negative or print to be intensified is placed in the Cubrome solution, which, by the way, may be used over and over again until exhausted, until evenly bleached, it is then washed in water for a few minutes in a subdued light or in the dark. If a plate, it is then darkened by means of a ten per cent. solution or any ordinary developer. Bromide prints are darkened by placing in a solution composed of 20 minims of the silver nitrate solution, of any diluted plate developer, then well washed and cleaned in a weak solution of nitric acid.

Instructions are also given for toning bromide prints to a sepia tone with the aid of Cubrome and sodium sulphide. Messrs. Edmunds and Co. supply the sulphiding solution for toning in bottles containing 8 oz., which, when diluted to the correct strength, make one gallon of solution, this is called Cubrome solution No. 2.

The print is first of all bleached in Cubrome, as above, and washed, it is then placed in a bath made by mixing one part of the No. 2 solution with twenty parts of water, wherein the print quickly assumes a rich sepia colour.

Prints toned by this method show no reduction of intensity in the original scale of gradations.

When bleaching with Cubrome for sepia toning only, there is no necessity to keep the dish covered to exclude light, neither is it so necessary to be careful not to wash too long before and after the short immersion in the dilute nitric acid bath, as is the case when bleaching with a view to intensification.

We have also secured some very good results by bleaching in Cubrome and toning in the following sulphocyanide and gold bath:—Gold chloride, 2 grains; ammonium sulphocyanide, 7 grains; five per cent. solution of .880 ammonia, 1 drachm; water, 2 oz.

In making up the above bath, add the gold to the sulphocyanide (dissolved in a little water), and make up to 2 oz. with water, and then add the ammonia slowly, stirring the while, when the solution should become colourless. Toning takes fifteen to twenty minutes, and the result is a purple to a purple-black colour.

The "Leto-Gaslight" Paper and Postcards. Sold by the Leto Photo Materials Company, Ltd., 9, Rangoon Street, E.C.

A greater variety in texture of surfaces, which is specially hard, and a great freedom from fog, are the characteristics claimed for the above. The surfaces are matt smooth, which has now a more delicate surface, and yields softer results than that of last season; glossy, rough, white, and cream crayon in both rough and smooth, give one a good choice. Any good developer may be used, but for soft effects and brown-black tones the following is suggested, and it gives excellent results:—Aduro-Schering, $\frac{1}{4}$ oz.; soda sulphite, cryst., 2 oz.; water, $12\frac{1}{2}$ oz. Potass carbonate, $\frac{1}{4}$ oz.; water, $12\frac{1}{2}$ oz. Shortly

before use mix equal parts of each. Development takes about 1½ minutes.

Special directions are issued for obtaining coloured tones on these papers by using the ordinary uranium or ammonio citrate of iron and prussiate, brown, red, and blue tones can be obtained, whilst for green tones the following is suggested:—Water, 2 oz.; oxalic acid, 90 grains; chloride of vanadium, 15 grains; sesquioxalate of iron, 7½ grains; perchloride of iron, 7½ grains; red prussiate of potash, 15 grains. Dissolve in the order named, one by one, and make up to:—Water, 35 oz. After toning, wash in water until the whites are clear. The tones given by this are very striking and satisfactory, and form a welcome change to the ordinary ones.

An Incandescent Studio Lamp. Holmes Bros., Manchester.

Messrs. Holmes Bros. have introduced a novel form of studio gas lamp for use with incandescent mantles which gives a light equal to over 700 candles. Five semi-bunsen burners are used, backed up by a 38 in. reflector, which may be raised or tilted, all complete, on a neat and portable stand. It is just the thing for the popular midget and stamp photographers. The lamp is also made with seven burners, giving a light of over 1,000 candle power, which can be used for cabinet busts. The lamps are fitted with a by-pass tap, so that it is not necessary to keep the mantles always in use, and the burners may be raised or lowered as desired. With a good portrait lens and a rapid plate good results may be obtained with about three seconds' exposure.

"Tiger Tongue" Bromide Paper. Sold by Elliott and Sons, Barnet.

To meet the demand for an extra rough bromide paper specially suitable for exhibition work, Messrs. Elliott are now issuing one under the above happy title. It has an extremely pleasing surface of rough texture, admirably suited for large work and broad effects, and the emulsion is of that high character, with rich, deep blacks and pure whites, as possessed by their other grades. Of course, any developer may be used, but the special metal developer recommended seems to suit this paper better than others. The formula is:—No. 1 Solution: Water, 80 oz. or 1,000 c.c.; metol, 400 gr. or 11 grammes; soda sulphite, 8 oz. or 100 grammes; potassium bromide, 50 gr. or 1.5 grammes. No. 2 Solution: Water, 20 oz. or 250 grammes; potassium carbonate, 2 oz. or 25 grammes. For use, take three parts of No. 1 to 1 part of No. 2. Development should be complete in about 1½ minutes. For those who desire to obtain sepia tones—which are, judging from our trials, extremely pleasing on this paper—the following is recommended:—Hot water, 70 oz., or 100 c.c.; hypo, 10 oz., or 14 grammes; dissolve and add alum, 2 oz., or 2.75 grammes. This bath must not be filtered, and can be used repeatedly. Place the fixed and washed print in the above solution for ten minutes, then raise the temperature of the solution to about 120 deg. Fahr. (about as hot as the hand can bear), and keep at this temperature until the print is toned, then immerse for ten minutes in alum bath, and well wash. Alum bath: Water, 10 oz., or 1,000 c.c.; alum, 1 oz., or 100 grammes.

A SERIES of lectures has been arranged to be given by various specialists at the London County Council School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C., on Thursdays. Admission is free by ticket obtainable at the school, or from the Executive Officer (Technology Section), Education Department, Victoria Embankment, W.C. The following is a list of lectures, the first having been delivered last night by W. Boutall, Esq.:—December 8, Snowden Ward, Esq., "Press Illustrations, with Points about Copyright"; December 15, Major-General Waterhouse, "Making Illustrations in India"; January 26, 1905, A. G. Cooke, Esq., "The Light and Power of Modern Illustration—Electricity"; February 2, E. F. Strange, Esq., "Lettering"; February 9, Frank Colebrooke, Esq., "The Illustrator and the Advertiser"; February 16, J. A. Corey, Esq., "Duplicate Plate Making—Modern Methods of Electrotyping and Stereotyping"; February 23, R. W. Sindall, Esq., F.C.S., "How Paper is Made"; March 2, Douglas Cockerell, Esq., "The Making of a Book"; March 9, J. J. Waddington, Esq., "The Humours of Process Engraving"; March 16, W. B. Dalton, Esq., "Historic Study in relation to Modern Illustration"; March 23, C. T. Jacobi, Esq., "The Printer and the Illustrator"; March 30, C. G. Zander, Esq., "Harmony and Contrast in Colour Mixing"; April 6, W. Strang, Esq., "Etching and Engraving"; April 13, Emery Walker, Esq., "Printing as an Art." As accommodation is limited, it is necessary that application should be made, at once, for tickets to admit to all or any of these lectures. Each lecture will commence at 8 o'clock prompt.

ROYAL PHOTOGRAPHIC SOCIETY.

TECHNICAL Meeting, November 22. Mr. W. Gamble in the chair. Mr. C. G. Zander read a paper on "Trichromatic Printing." He dealt in this paper only with the pigments or printing inks required. A knowledge of the principles upon which three-colour work is based was assumed, and only a brief recapitulation was given. typographical reproduction positive printing blocks are made by printing in pigments, which, broadly speaking, may be termed complementary to the respective primary colour sensations. Thus the negative block will be printed with a colour reflecting all the spectral rays except red, viz., cyan blue (peacock or turquoise blue); green negative block with a colour formed by the two sensations stopped out, viz., crimson or magenta; and the blue-violet negative block in the same way with yellow of the hue of the spectrum line. He suggested that all who engage in three-colour work should call yellow, red, and blue the primary colours, and when speaking red, green, and violet, call them the primary light sensations. Zander then dealt with the laws which govern all pigment mixtures. It was useful to arrange all the pure spectrum colours and the complementary hues of purple or magenta round a circle, thus forming a curving range of colours. It is best to arrange them so that the complementary colours are placed at the two poles of a diameter. Blue is placed in the centre, and the subdued or saddened hues result from the admixture of neutral grey to the pure colours are placed

the circle at a proper distance from the black. A coloured gram so built up was projected upon the screen, and Mr. Zander showed how, within certain limits, it was possible to reproduce all primary colours used in the graphic arts, painting and printing. There were, however, numerous bright colours which cannot be obtained by any possible mixtures of the three primary colours, viz., scarlet, orange, emerald green, ultramarine blue, and the brilliant hues of the aniline violet. Here one perceives at the limits of three-colour work. The assertion that three-colour printing can produce anything, and will ultimately entirely supersede chromo-lithography, with its numerous printings, was one with which Mr. Zander disagreed. The range of colours in the three-colour method is strictly limited, whilst that of chromo-lithography is quite unfettered. The latter had the advantage over the former that it gave homogeneous flat shades and tints, and delicate gradation with ease, certainty, and evenness through long runs which three-colour work could not hope to achieve so satisfactorily in its present comparatively undeveloped state, particularly in half-tone printing. Chromo-lithography, on the other hand, could not hope to give the minuteness of detail which three-colour printing afforded through the aid of photography. Both processes, therefore, have their sphere of work. Mr. Zander pointed out, however, that chromo-lithographers had made three-colour photography serve them in the analysis of any given original, and that by its means they had been able to reduce the number of printings which would result from an ordinary colour analysis made by the unaided eye of the artist. Mr. Zander then defined the ideal inks for three-colour printing as transparent in two-thirds of the spectrum, with a steep absorption band covering the third part, which corresponds with the main portion of the colour-sensation curve transmitted by the relative negative. These three absorption bands should cover, as nearly as possible, the whole of the spectrum when placed side by side. The position of the two dividing lines of the three bands should be, roughly, the "B" and "F" spectrum lines. Mr. Zander said that there was, however, a fairly great latitude permissible in the hue of the printing colours. The individuality of the printer was an important factor. With the same blocks, machine, paper, and inks hardly any two printers will produce identical results. Some use ink sparingly, others like it to run freely, some work cleanly, others like to add all sorts of concoctions into the ink. Other factors are the press, which must register accurately, the paper (note the difference caused by printing on unsized and on highly calendered paper), the blocks, and the inks. The inks which approach the ideal conditions most nearly are of aniline lakes of a more or less fugitive colour in direct sunlight. They are in consequence useless where permanence is essential. Such inks, however, besides being fugitive, have less covering power, and reflect too much white. In short, the ideal inks do not exist, and if they were available, the blockmaker still is very deficient. The commercial or permanent inks differ from the theoretic in several respects. The red and blue lack luminosity, and cannot produce such brilliant secondary colours as violet, magenta, scarlet, orange, green, peacock blue, etc. The reds are deficient in violet, and the blues in green. The yellow should be somewhat greenish, for the reason that the red has an excess of yellow and the blue too much violet. A slightly reddish yellow would therefore give too dirty a green. To produce the best possible results, however, one should choose the inks first and adapt the photographic process to them. Mr. Zander advised, therefore, that with red and blue as nearest approached the scientific ideal should be taken—the red luminous and purplish, and the blue greenish. The yellow must be of the correct hue—deviations in it are more noticeable than in the red and blue. The blockmaker must then strive to work to the selected inks, which should not be changed without ample reason. Mr. Zander expressed the belief that blockmakers themselves were largely responsible for the unsatisfactory condition of printings. The inkmaker was also no paragon, and between the two the printer's lot was not a happy one.

RICHMOND CAMERA CLUB.

On 24th ult. a discussion took place on "Animal Photography." It was opened by Dr. Rodman, who began his remarks by stating the principal requirements for success in that class of work. These he enumerated as: patience, a good and suitable light, rapid plates, and a quick lens—but, before all things, patience. It is often necessary to wait for a long time before the subject will assume a suitable

attitude for a picture. The light must be good, but not too strong, or hard pictures lacking in detail will result. Rapid plates, and a lens working at a large aperture so as to secure good results with short exposures, are indispensable.

For the purposes of the evening, Messrs. Newman and Guardia had kindly lent Dr. Rodman one of their new "Square Reflector Reflex" cameras, which are specially adapted for scientific work, such as animal photography. This is a hand camera of the highest quality as an instrument of absolute precision, and is equally suitable for the amateur or the expert. It is of the single lens reflex type, in which the image can be seen and accurately focussed right up to the moment of exposure by means of a square reflector which shows the full area of the picture, both horizontally and vertically at the same time. A special binocular focussing eye-piece can be provided for focussing critically the most difficult subjects, and a back focussing screen enables the camera to be used for stand work.

A special feature of this new type of camera is that it takes lenses of normal focus and also long focus and telephoto lenses. The camera shown was fitted with a Zeiss Double Protar, series VIIa, $5\frac{1}{2}$ in. focus, working at $f/6.3$, the back combination having $9\frac{1}{2}$ in. focus, and working at $f/12.5$, the double extensions being effected without racking. A notable feature of the camera is that all the mechanism, including the release, is on the right hand side, leaving the left hand free for holding the camera, a great advantage in slow exposures. It has a rotating back, which takes a dark slide, a changing box, or a roll holder. Mr. Guardia also procured and lent for the occasion a very fine set of photos of bird life taken by Mr. Smith Whiting, and a unique enlargement from a quarter-plate photo of a sitting hare taken by Dr. Frank Penrose with a single combination of 13 in. focal length, all of which were taken with "N. and G." Reflex cameras.

After these had been examined, a number of slides by Dr. Rodman, Messrs. Gibson, Cheese, Dale, and Major Latham were thrown upon the screen. A few members made further remarks upon the subject, and the meeting was terminated with a vote of thanks to Dr. Rodman and those who had shown the slides, and also to Messrs. Newman and Guardia for their contribution to the evening's exhibition.

ABERDEEN.

UNDER the auspices of the Aberdeen Photographic Association, Mrs. W. M. Ramsay, on Friday night, delivered a lecture entitled "With my Camera in Asia Minor." The announcement of the lecture drew a large attendance to the society's rooms, and a number of ladies were present. The lecture, though informal, was delightful. It dealt with the districts covered by the recent archaeological researches of Professor Ramsay, and the historical references were blended with many diverting reminiscences of the adventures of the party, which included Professor and Mrs. Ramsay, their son and daughter. Many glimpses were given of picturesque scenery, of mosques and minarets, of ancient monuments and temples and tombs, and there were brought into relief various racial types and native customs, while over and above all the maladministration and general incompetence of the Turkish Government were vividly emphasised. Beginning at Tarsus, the lecturer, by means of a varied and beautiful collection of slides from photographs taken by herself, took her audience over a very wide and scattered but classical region, including Iconium, the Taurus Mountains, the Cilician Gates, Smyrna, Laodicea, Philadelphia, Thyatira, Pergamos, and Sardis. The lecture was bright and racy, but full of information, and the personal allusions it contained gave it added piquancy.

CROYDON CAMERA CLUB.

NOVEMBER 23.—"The Hand Camera and How to Use It," in Mr. F. M. Sellors's hands, formed a most instructive and interesting topic, but which, owing to the extent of the ground covered, cannot adequately be dealt with in condensed form. The various types of cameras, magazine, folding, roll-holder, flat film, twin lens, reflex, including focussing cameras and those of the so-called fixed focus, were each in their turn considered, and their respective merits and demerits pointed out. A hand-camera was essentially a compromise, and a gain in one direction was almost invariably accompanied by some sacrifice in another. As to finders, Mr. Sellors preferred a full-size one, by which focussing could be done, as in the reflex and

twin-lens patterns. It was, however, 'unfortunate' that with the reflex type the release of the mirror frequently created a jar at the critical moment, rendering all but high-speed exposures out of the question. A rectangular folding wire finder, if properly used, indicated correctly, but necessitated a somewhat awkward, and invariably conspicuous, method of holding the camera. With reference to shutters, in Mr. Sellors's opinion the focal-plane undoubtedly held the premier position for all-round work, owing to its high efficiency, but whatever form of shutter was adopted, very little reliance should be placed on any speed indicator supplied with it.

In the discussion which followed, Mr. Rogers said he had found supplementary lenses, of the planiscope type, useful for lengthening the focus. Mr. Kough pointed out that the ordinary roller blind shutter gave nothing between a time exposure and a reputed 1-15th second. The slowest "instantaneous" exposure might, however, be materially lengthened, by attaching to the setting-cord small pieces of lead. During the evening a question arose as to whether the position of a light filter had any effect upon exposure. Mr. Salt said, so far as he could see, a filter stopped the same proportion of incident light whatever its position, whether in front or behind the lens, or immediately adjacent to the plate, and the necessary exposure would be the same in all cases, but this view was not shared by Messrs. Sellors, Terry, Isaac, and many others.

SIDCUP LITERARY AND SCIENTIFIC SOCIETY.

It was a large and delighted gathering that assembled at Sidcup Public Hall recently on the occasion of the annual conversation held under the auspices of the Sidcup Literary and Scientific Society. The hall had been decorated with great taste, a feature being a floral screen, composed of a series of arches arranged in front of the platform. About the platform graceful palms were arranged, and large full-blossomed plants of heather were placed along the edge. The body of the hall was prettily arranged with artistic devices. As might be expected from such a society—whose aims and objects in Sidcup are increasingly appreciated, as shown by the rapidly increasing membership—intellectual feast was on this occasion allied with social enjoyment. An excellent programme of orchestral music was rendered by members of the Sidcup Musical Society, under the direction of Mr. A. E. Butterworth, and with Mr. E. Bloxham as leader. Mr. Clayton Beadle was busy throughout the evening explaining the methods of manufacturing artificial silks from pinewood, with the aid of chemicals. Some beautiful specimens of brocade and other silken materials, which were displayed to view, demonstrated the wonderful results that can be obtained from crude firewood when submitted to chemical treatment. Mr. Beadle is one of the patentees. Dr. Stevens, his partner, rendered him valuable assistance and devoted most of the evening to demonstrating the manufacture of hand-made paper, and paper-making generally was explained with the aid of various models of machinery, chemicals, and materials. A series of photographs was also shown illustrating the development of the industry, from the tree logs to their conversion into paper. An instrument was exhibited for the first time—an invention of Dr. Henry P. Stevens' for measuring the qualities of blotting papers. Mr. Doncaster, who was representing Messrs. Sanger Shepherd and Co., gave a most interesting demonstration of colour photography with the aid of numerous lantern slides made from the actual photographs. The most beautiful colours were shown to be capable of faithful reproduction from Nature by means of the camera. In the small hall Mrs. Scott repeated to smaller but admiring gatherings her photographic illustrations of the growth of plants, as shown before the British Association this year. The gradual opening of buds and leaves was illustrated by the cinematograph. Mrs. Scott explained that some of the photographs took three weeks to complete.

At Falkirk, a man named John Patrick Ferguson, hawker, admitted having broken into a temporary booth on Callendar Riggs and stolen a camera and a quantity of photographic accessories. It was stated on his behalf by an agent that he was under the influence of drink at the time, but on coming to himself he assisted the police to recover the articles. Sheriff Young sent him to prison for sixty days.

News and Notes.

THE entries for the Southampton Exhibition close on Monday next, December 5.

WE have received a copy of the Gloucester Diary for 1905, which, as in previous years, we have no doubt will prove useful to us.

HERR MAX WOLF, director of the observatory on the Königsstuhl near Heidelberg, has discovered a new planet of the thirteenth magnitude by means of a celestial photograph.

WITH regard to the flexible screens suggested by Mr. Howard Farmer, Mr. Elea Luboshey informs us that they can be obtained from J. B. Campbell, of 163, Renfield Street, Glasgow.

A RECEIVING order was made last week at the Manchester Court on a creditor's petition against Franz Baum, who resides at Winton House, Winton Road, Bowdon, and carries on business as a photographer at 84, Deansgate, Manchester.

MR. J. ROBINSON read before the members of the Border Camera Club, on 22nd ult., a lecture lent out by the "People's Friend," entitled, "The Capabilities of the Camera," illustrated by seventy excellent slides showing various ways in which the camera can be utilised as a recorder of events, artistic composition of pictures, as well as the ludicrous production of distortionate figures.

THE eighteenth annual Grantham Industrial and Fine Art Exhibition, which is always the most looked-forward-to event at Grantham, has been fixed for January 18, 19, and 20 next. There are 12 classes for competition, including painting in oils and water-colours, photography, etc., etc. Particulars, in schedules, to be obtained from Mr. Geo. Jackson, Launde Terrace, Grantham.

WE have received a circular setting forth in detail the proposal to hold an international photographic trades, photographic art, and picture postcard exhibition at Earl's Court, from March 16 to 19, 1905. It is proposed to include every possible and existing application of photography. The organising managers are F. M. Bridgman and Geo. D. Smith, and the Hon. Secretary, Robert Hilton, of 125, Finsbury Pavement, E.C.

MR. W. S. STUART, of 2, The Quadrant, Richmond, has again been honoured with a command to attend at Windsor Castle, this being the second time within a week. On Monday last Mr. Stuart had the honour of photographing his Majesty King Edward, H.M. Queen Alexandra, H.M. the King of Portugal, H.M. the Queen of Portugal, H.R.H. the Duchess of Fife, and H.R.H. Princess Victoria. A large number of portraits were taken both separately and in groups.

THE entry forms of the Fourth International Exhibition of the Blairgowrie and District Photographic Association are now ready and can be obtained from the Hon. Secretaries, The Public Hall, Blairgowrie. Arrangements have been made whereby pictures sent to the Scottish National Salon at Glasgow, if entered for this exhibition, will be forwarded to Blairgowrie free of charge to exhibitors. If desired, pictures can be forwarded direct from the Blairgowrie Exhibition to the Glasgow Southern Exhibition carriage paid.

THE Hastings and St. Leonards' Photographic Society's Exhibition will be held at the Public Hall, Hastings, on January 11, 12, and 13, 1905. There will be six open classes, six for members' work, and one special open only for pictures rejected at the Salon and the Royal Photographic Society's Exhibition. Awards:—A silver and a bronze medal will be offered in each open class; the society's massive gold medal will be awarded to the best picture in the exhibition; in the special class there will be three awards, the president's special silver plaque and the society's silver and bronze medals. All communications to be addressed to the hon. secretary, Mr. Fred. Judge, 2, Wellington Place, Hastings.

PLYMOUTH Photographic Society.—At a meeting of the Plymouth Photographic Society, at the Athenæum, last week, Messrs. Wilfrid Grist and J. Trouern Trend gave an interesting lecture and demonstration on lantern-slide making. They made slides from about a dozen negatives, and developed, toned, and fixed them in full view of a large audience. By the process adopted by the demonstrators various colours were obtained. The slides were dried by methylated spirits, and shown on the screen within a very short space of time, some good results being secured, although the conditions under which they worked were not very favourable, the rapidity with which

had to be prepared not being conducive to the production of pictures.

The Birkenhead Photographic Association met in the Y.M.C.A. last week, Mr. R. T. Russell presiding. Dr. Harrington gave a lecture on "Etching and Engraving." He traced back the beginning of line engraving and etching to the 15th century and mezzotint to the 17th century, and described in detail the process of etching, mezzotint, and line engraving, illustrating them with a number of fine slides, detailing the various processes a plate has to undergo before the print is complete. Some fine examples of Turner's work were exhibited, and a number of slides depicting Rembrandt and Vandyke's work. Coming to a later period, many pictures were shown by Sir Seymour Haden, Whistler, Cameron, Watts, Hall, and Strang, showing the advance that has been made in art.

On an afternoon last week a series of interesting demonstrations of photography were given in the Y.M.C.A. Buildings, Aberdeen, by Mr. Burr, a representative of Kodak, Limited, and Mr. James Anderson, photographic dealer, Aberdeen. There was a large gathering of the general public. The demonstration was principally for the purpose of showing how photographs could be produced without the use of a dark room, an exhibition being given with a daylight developing machine. Thereafter about ninety slides were thrown on the screen taken from Kodak photographs. The views, which were of a very interesting and varied character, included many very fine scenes showing excellent detail and fine tone. Some of the photographs shown were awarded prizes in the recent £1,000 Kodak competition.

The annual conversazione at the Y.M.C.A. Rooms, Ipswich, on Thursday evening, was successful in every respect. No matter where turned, there was something to amuse or entertain, and the large number of people who gave their patronage were well rewarded. A photographic competition was a great attraction to the members, and over 180 entries being received for the five sections. Mr. L. Man (from Mr. Adolphus Tear's) was the judge, and he made his report from a very creditable exhibition as follows:—Landscapes: 1. C. Ridley. 2. F. A. Dent. 3. W. Goodchild. Seascapes and Scenery: 1. W. Goodchild. 2. F. A. Dent. 3. K. G. Reeve. Architecture: 1. F. A. Dent. 2. B. C. Ridley. 3. W. C. Collinson. Photographs of moving objects: 1. F. A. Dent. 2. B. C. Ridley. 3. W. C. Collinson. Picture postcards: 1. W. Goodchild. 2. W. C. Collinson. 3. S. A. Felgate.

New cinematograph pictures of country scenes are obtained from this week by a case at Barnet County Court. William George was mulcted in £5 damages and costs for trespassing at Green Farm, Arkley. Mr. Poole, solicitor for Mr. King, the plaintiff, described the trespass as particularly impudent. Defendant drove up with two van loads of people and entered a fifteen-acre field, untethered the horses, and trod down the aftermath, on November 20, doing damage to the amount claimed. No permission was asked or obtained. Defendant admitted that he had done so in entering the field, but thought the case would be met without going to court by his paying, perhaps, £1 to a local hospital. He had only two wagenettes, and thirteen persons all told. They took 100 or 12,000 photographs, but did not roam over the whole fifteen acres.

The Hiring of Cinematograph Films.—J. Gaumont and Co., of the Court, have just instituted a special hiring department for cinematograph films, so that for a very reasonable fee a cinematograph film can be easily sandwiched in an ordinary lantern show or for evening entertainment, and the variety of films thus placed at exhibitor's command will prevent anything like satiety with one particular subject. Messrs. Gaumont have also, in conjunction with Messrs. Peach and Co., Limited, of 48, Holborn Viaduct, E.C., made arrangements whereby one of their first-class chrono projectors may be obtained on the "Times" instalment plan, and an instrument is delivered at once, although the payments for the same may be extended over six or twelve months. Considering the necessarily heavy cost of a perfect projector, this scheme should be of immense advantage to those of limited means, as there is no increase of the price. Films may also be obtained in the same way, but in this case there is a slight increase in the price over that for cash. Messrs.

Gaumont will be pleased to send any one full particulars on receipt of a postcard.

THE Photographic Theatre.—Mrs. Langtry, on the 27th ult., opened the Photographic Theatre at 154, Holland Park Avenue. There was a crowded audience to witness this somewhat novel event, and a large number of ladies and gentlemen connected with the musical and theatrical profession were present. The theatre where the ceremony took place is 80 ft. by 40 ft., and is full of novelties introduced by Mr. Mount Stephen Gillard, one of the inventors of the "Photolinol" patents. The stage is 24 ft. by 17 ft. Theatrical groups can easily be photographed without cramping into small space. As to "Photolinol," it might be mentioned that the patent duplex photographic linen invented by Mr. Otto Fulton, managing director of Photolinol, Limited, and Mr. William Gillard, is quite a new departure in photographic art material. The material is practically indestructible, is waterproof, impervious to the action of the sun, and has a high transparency. It can be rolled, posted, creased, or stretched without the slightest injury to the photograph. The company are the possessors of the only mercury vapour lighting apparatus for photographic purposes in England. They also employ a system of clustered incandescent electric lights, 10,000 candle power, which forms a substitute for the sun's illumination. When the visitors had all assembled Mrs. Langtry appeared upon the stage and declared the theatre open.—"Standard."

The second annual dinner of the Cardiff Windsor Photographic Society turned out a complete success, 105 members sat down to dinner, and this number was swelled to about 160 before the proceedings were over. J. Bell Harrison, Esq., presided, and gave a short history of the Society, and thought that it was one of the most successful societies that he had ever been connected with. An excellent menu having been prepared, the members enjoyed themselves thoroughly, after which an excellent programme of entertainment was provided for by Mr. McBratney, to whom credit is due for the excellent way in which he arranged both dinner and entertainment. Mr. Fred. Fox, the President, was presented with a ten-guinea camera which was subscribed for by the members, the generous use of his encyclopædic knowledge, energy, and geniality having done much to ensure the success of the Society. Previous to the dinner, Mr. J. Bell Harrison organised a competition in which members took a great deal of interest, three of them being successful in obtaining silver and bronze medals, namely, Messrs. Brown, Palmer, and W. Mathew Smith. Mr. J. Bell Harrison was also pleased to subscribe £5 5s. to the funds of the Society. The proceedings terminated at 12 o'clock, all the members having expressed their approval in very decisive terms. The dinner tickets and menu cards were produced on bromide paper from a clay model which the President prepared. The club is to be congratulated on the excellent attendance and the energetic way in which the members continued to support such a deserving society, the subscription being only 7s. 6d. a year. The members have the free use of dark-room, dishes, lockers, enlarging lantern, optical lantern, copying camera, library, and studio, etc., for which a complete set of apparatus has been provided. The Society holds its meetings two nights a week, at which lectures are read from the Royal Photographic Society and also given by the members themselves. An exhibition will be held in February, which is hoped will eclipse everything done hitherto in Wales.

We have received from Mr. Robert C. Carter, of 33, Enbrook Street, Queen's Park, Harrow Road, W., details of the International Photographic Exchange, a copy of the magazine, and the following explanation of the purpose of this association. At present the subscription for England is 1s. 6d., but after January 1, 1905, it will be raised to 2s. 6d. Mr. Carter will be pleased to furnish any one interested with full details. The object of the Exchange is to afford our members an opportunity of exchanging, through correspondence, photographs, stereoscopic views, and lantern slides. To circulate albums of photographs among such of our members as may contribute prints for that purpose. To encourage and assist our members to the better enjoyment of photography by affording that stimulus which association and example always provide. In enabling our members to form collections either of miscellaneous photographs or of some particular kind, such as historical, typical, or artistic, this society stands unrivalled. It is admitted by all that more useful photographic information may be secured by the exchange of prints and the attending correspondence than by any other method. Class I. includes

regular members or those desiring a general exchange. Such members may limit their exchange or specify a certain class or kind of work desired, in their exchange notice. Class I. members are expected to answer promptly all letters in which stamp is enclosed for reply. Class II. includes members who, from lack of time or uncertainty as to address, might find it inconvenient to always reply promptly to inquiries concerning exchange. Class III. members will receive few, if any, unsolicited exchanges, as they are expected to acknowledge only such correspondence as they may themselves invite. Class III. includes members desiring to enjoy only the benefits of the circulating albums, the monthly publication, or both. All members, regardless of the class to which they belong, in order to receive the albums must send prints to the Director of the Circulating Albums for insertion therein. In no case are Class III. members to be asked to exchange. The word Class, as used in this connection, has no reference to the grade of work turned out by a member. Any one interested in photography and willing to conform with the rules of the Exchange is eligible, amateur or professional, tyro or Salon medallist. All can find congenial correspondents and each can derive, as his individual taste may suggest as desirable, benefits from his membership in this Society. On joining, each new member is given an exchange notice in the "Photographic Exchange," setting forth his number and designating the Class in which he wishes to be placed. Mention is also made of the kind of work offered and desired in exchange, if any, together with such other detail as he may furnish. All members, irrespective of the Class in which they are enrolled, are privileged to send prints to the Album Director for the Circulating Albums, entitling them to a place on the route list of all such as contain one of their prints, as well as on that of such other albums as it may be found convenient to so route. The most liberal contributors to the albums are understood to be the most deeply interested, and, of course, are given the preference when routing foreign or other special albums. A numerical correspondence system, translations of which are furnished all foreign members, permits the exchanging of prints between those using different languages, with the greatest facility and satisfaction. All exchanging is done by direct correspondence on any agreed basis.

Commercial & Legal Intelligence

ATTEMPT at Suicide.—Walter Ancell, thirty-nine, photographer, of Canterbury Road, Ball's Pond, was charged last week, on remand, with attempting to poison himself with laudanum. He took this in a public-house, and Dr. Carey Barlow, who was called to him, said the poison was taking deadly effect when the remedies were applied. It transpired that the prisoner was depressed through lack of work and too much drink. He now said he would become teetotaler and take a more cheerful view of life. His father, too, said he would look after him, and Mr. Chapman allowed the prisoner to go away.

PHOTOGRAPHER'S Failure.—At Middlesbrough, Mr. R. C. Clifford, photographer, of Wilson Street, Middlesbrough, appeared before the Registrar (Mr. H. S. Crosby) to undergo a further examination in bankruptcy. The debtor admitted, when questioned by the Official Receiver (Mr. Stubbs), that there were some bank shares included in the marriage settlement. These had originally belonged to his father, who bequeathed them to him. He, however, denied the statement that he had these in his possession. He had never had them in his possession. Further questioned by the Official Receiver, debtor said that £12 10s. which he had paid to his solicitor he had borrowed from Mr. Turner. The cause of his failure was that he had not made sufficient in his business to meet his household and personal expenses. He had previously stated that he had lost £400 on an off-beer licence at Redcar. This must have been a mistake on his part, as he had only lost £200 on the business. The Official Receiver here pointed out that he had included this in his deficiency account, and if he had only lost £200 on the Redcar business the deficiency was not all accounted for. Further questioned, debtor said he had lost £102 during the last year. He had made no speculations, nor had he gambled to any extent. The Registrar, in further adjourning the examination until next Friday, said that the statements were not satisfactory, and suggested that debtor could find a better account than that which had been submitted.

Correspondence.

- * * *Correspondents should never write on both sides of the paper. notice is taken of communications unless the names and addresses of the writers are given*

THE PROPOSED BENEVOLENT ASSOCIATION.

To the Editors.

Gentlemen,—I am pleased to see that an effort is being made to revive the benevolent fund, and I hope it will be successful, as something of the kind is sadly needed. Why should photographic assistants not have a strong union amongst themselves to obtain a living wage, help each other in times of sickness and out of employment, and in time some sort of a pension scheme could be evolved? There should be enough assistants in the business now, and photography as a whole are not less humane than their fellows to make something possible; but there seems to be such an apathy, indifference, assumed superiority amongst the average operators, etc., to anything in the shape of trade unionism, which is hard to understand, is both foolish and hurtful to their own interests. I should strongly advise all assistants to at once rally round the Benevolent, and perhaps in time some strong organiser will arise amongst them to lead them to action in the matter of combination. I write this that assistants would in future avoid being placed in such a position as I myself, after working for thirty years, and getting very near half century old. I find it almost impossible to get a situation; six months vainly trying I find myself face to face with I scarcely know.

DARKNESS

"THE IDEAL PORTRAIT LAMP."

To the Editors.

Gentlemen,—In referring to our Ideal Portrait Lamp in your current issue you mention the fact that the lamps can be seen and demonstrated at Messrs. Gardiners, Glasgow, but you do not quite make it clear that they are only agents for the lamp.

We are always pleased to exhibit the lamp to anyone interested in our show rooms here, and shall be glad if you will make a note of this effect in your next issue. —Yours truly,

HOUGHTONS LTD

88 and 89, High Holborn, London, W.C.

November 23rd, 1904.

SOME NOTES ON ACETYLENE.

To the Editors.

Gentlemen,—When rising in a 'bus a few weeks since I noticed the light was very brilliant and that the flame was small. Concluding that it was some form of acetylene I examined it and found that the whole apparatus was very compact, and if nothing more was included than was visible it could be used in an optical lantern.

I am not now quite sure of the name it bore, but believe it to be "dissolved acetylene"; the address was 3, Victoria Street. It appeared to me to be an ideal light for an enlarging lantern.—Yours etc.,

ANON.

PROBLEM NO. 2.

To the Editors.

Gentlemen, Referring to the letter in your issue of the 18th inst. under the above heading, may I say that it seems to me to be a plausible waste of space in your valuable columns to accord a place to a communication which is neither instructive nor, I take it, of general interest, and can only reflect the utmost contempt and credit upon the writer.

The original letter at which this tirade of sarcasm is directed though perhaps an unusual one, is by no means ridiculous, as, the writer having been out of touch with photography for some years, and wishing to take it up again as a means of livelihood, what is more feasible than for him to write to the B. J.—which is generally regarded as being an authority on matters photographic—for any advice you could give him, which, by the way, was practically nil?

There is small likelihood of the P. P. A. becoming a paragon society, and I fail to see why a man should be boycotted or ridiculed on account of his having been a parson.

our ranks are crowded sufficiently now, but, still, "Live and live," and above all be fair.

There is one point I do really admire about your correspondent, his extreme modesty, as evidenced by his apparent desire to avoid undue notoriety and overwhelming commendation by his adoption of a nom-de-plume.

In conclusion, it is a matter of regret that you would-be humourist should not preface his brilliant and highly intellectual letter with an appropriate quotation, as, for instance, Shakespeare's "Write me you an ass."—Yours faithfully,
T. HOPKINS.

Kensington, W.
November 25, 1904.

ANOTHER PROBLEM FOR THE EDITORS To the Editors.

Gentlemen,—Seeing the terrible pass that photography has got to, a business in a country town is at best little better than starvation. I am at present located the local photographer had, in the old plate days, all the photographing that there was about the place. But now every association, every club—no matter which—every church picnic, every Sunday school picnic has its own smart amateur who does things at prices that no professional can touch. I could not get paid for the same class of work, but then I could not get the chance to do it. The professional used to get all the orders; now he gets none of them. The postcard having killed the view trade, there is little now left to us but an occasional thing, and for every half-dozen orders we get we have to take two plates, and give a retouched finish at 6s. per half dozen. So I have been thinking of making a change, but before doing so I should like to consult you, Mr. Editor, as I have hitherto done in all matters connected with my business before making the change. I may state that I would like to get an appointment as manager of a large steam shipping company; I should not care to take the management of a company of tramp steamers, I should prefer one of the first-class passenger lines. To begin with, I would accept of the management of any of the more important of their provincial branches. I may say that I know a good bit about shipping. When a boy (I am now an old chap) I was a great hand at model yachts, in fact, I was the real inventor of the centre-board. I had a flat yacht, built with an adjustable keel, that raced every boy's yacht in our village. I may further state that I was a very clever boy, and I now spend a lot of my spare time wondering why clever boys grow up into very stupid men. I have another reason for my anxiety to abandon the camera: my eyesight is failing, so I must either get the management of some high-salary paying concern or go in for a pair of spectacles.

J. M. P.
P.S.—If you happen to be a shareholder of the P. and O. or of the Inland Company, you might mention to the directors that I am open to accept such an appointment. If you do, I am positive that the Company will be ever indebted to you.

J. M. P.

THE BOVRIL COMPETITION. To the Editors.

Gentlemen,—Could you kindly inform me if the recent Bovril Photographic Competition results have been published, as I, and a number of my friends, are anxious to know?—Your sincerely,

November 17, 1904.

FAKER.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free (UNITED KINGDOM AND THE CHANNEL ISLES).

	s. d.	France, Belgium, United States, Canada, Australia, Africa, New Zealand, Newfoundland, Germany, Russia, Portugal, Spain, Italy, Egypt, India, China, Japan, &c.
One Year	10 10	13s.
Half Year	5 5	
Quarter Year	2 9	

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

Answers to Correspondents.

***All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**

***Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**

***Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**

***For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

W. E. Sorrell, 55, Topsfield Parade, Crouch End, London, N. Photograph containing Mayor, Aldermen, Councillors and Principal Officers of the Hornsey Borough.

J. L. Hart, 2, Mill Street, Crewe. Photograph of the Crewe Alexandra Football Team 1904-1905.

J. H. Moody, High Street, Aberavon. Port Talbot, Glam. Photograph of Alderman T. Owen and Mr. Bell, M.P.

Mrs M. Le Tourneau, 219, Regent Road, Salford, Lancashire. Photograph of the Everton Football Team 1903-1904.

O. Baumgart, 118, Commercial Road, London, E. Photograph of J. Brodetsky. Photograph of S. Brodetsky.

J. Shivas, 46, Queen Street, Peterhead. Photograph entitled "The Tail of the Storm."

J. F. Forster, Tangier Buildings, Whitehaven. Photograph of the Cumberland Rugby Football Union Fifteen, 1904-1905.

A. G.—Threaten an action for illegal detention unless returned within 48 hours, and then proceed.

J. T. S.—Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C., can supply you with the works in question.

D. D.—The camera named is sold by Houghtons, Ltd., 89, High Holborn, W.C., who would send you all information.

"Mac" (Newark).—We do not know the material under that name.

It is evidently an article fairly well known in America, though not here, or, at least, under the name given.

T. Hunt.—The manufacturers' address is Birmingham, and they only, we believe, supply dealers. As you have had no dealings with them, you can only treat with the local chemist who supplied you with the goods.

"A. W." asks:—"Having been engaged to photograph group, when members of the Royal Family were present, would I have the privilege of printing on my mounts, 'Patronised by Royalty'?" In reply: Certainly not.

FACTORY ACTS.—H. WHITE says:—"Will you be good enough to say how the new Closing Act affects professional photographers in their business on week-days and Sundays?" In reply: We scarcely understand your query as to the "New Closing Act," but see answer to "Don't You Know."

"BAS."—The chief fault is that you have not obtained satisfactory sharpness all over the plate. Probably a smaller stop would have helped you in this, and, in any case, you should have focused on a point with full aperture halfway between nearest sitter and the furthest, and then stopped down till you got all sharp. Your light was also too much in one place; for a hall that size, two, or even three, lights should have been used at almost equal distances from the camera.

DEVELOPER.—WM. GREEN asks:—"Will you please state a developer that gives straw-coloured negatives like pyro-ammonia, and also gives soft results for portraits?" In reply: Most of the newer developers will yield more or less stained negatives if some of the sulphite of soda be omitted. Formulae for all of them will be found in the "Almanac." Why not employ pyro if you wish for the yellow tint? It cannot well be improved upon in this respect.

"ANILINE DYES" asks:—" (1) Where can I get dyes for colouring lantern slides, or, how can I make the aniline dyes permanent? I have bought the dyes from chemists, but find the colours fade. (2) Are self-toning papers as permanent as those toned with gold?" In reply: (1) So far as we are aware no aniline dye is absolutely permanent, but some are more so than others. Messrs. Mawson and Swan, and Penrose and Co. stock a great number of these dyes. (2) Yes; certainly.

OPINION WANTED.—"E. D." says: "I should be extremely obliged if you would kindly pass your opinion on the enclosed retouching and tell me where I can get a book on retouching and operating." In reply: The work is moderately good, but the negative did not require much retouching. One cannot form an opinion of your ability from such a negative. "The Art of Retouching," by Robert Johnson, is a good work on the subject. "The Studio and What To Do In It," by H. P. Robinson, is also a good book.

REGISTRATION OF COPYRIGHT.—"J. H. G." asks:—"Can you inform me where to get a photograph copyrighted, and the cost of same? Size $8\frac{1}{2}$ by $6\frac{1}{2}$." In reply: If you send us two copies of the photograph, and one shilling and sevenpence in stamps, our publishers will effect the registration for you. The size of the photograph, whether large or small, makes no difference in the cost. If you read the notice heading this column every week, you will see that we do not answer correspondents by post.

NEGLECTED ORDER.—SALTER AND SONS write:—"You would greatly oblige by advising us on the following:—On October 10, 1904, we sent two prints to Messrs. —, who advertise making cabinet negatives from prints, with P.O. for cabinet negatives. They did not acknowledge receipt of order, and will not answer any communication. Will it be possible to regain possession of prints, as they are valuable and belong to our customers?" In reply: You can certainly recover the money sent, and the value of the prints, by suing the firm in the County Court.

OPINION WANTED.—"REFLEX" asks: "Will you kindly let me know which, in your opinion, is the most serviceable reflex camera on the market?" In reply: It is quite against our rule to express any opinion on the merits of any particular maker's goods. All the cameras supplied by established makers can be relied upon. Our correspondent's best plan will be to consult the advertisement columns of the JOURNAL and the "Almanac," and then call and see at the dealers' the different forms of apparatus, and select that which, in his idea, will best suit him and his pocket.

DEVELOPER.—R. H. DAVIDSON says:—"I should be greatly obliged if you would tell me:—(1) Of a formula for hydrochinone developer introducing ferrocyanide of potash. (2) The use of latter in the developer. (3) Is there any danger of fog in using it on rapid Iso plates?" In reply: (1) The following is taken from "Wall's Dictionary of Photography":—Solution A: Water, 550 parts; hydrochinone, 10 parts; sodium sulphite, 10.5 parts; ferrocyanide of potassium, 2 parts. Solution B: Sodium hydrate, 60 parts; water, 550 parts. For use, equal parts of A and B. (2) The ferrocyanide acts as an accelerator. (3) No.

A BUSINESS MATTER.—"E. H." asks: "Will you kindly answer me what could be done in the case of a customer bringing a photograph to us to be copied, at the same time requesting us not to supply anyone else with copies, and when another party came to our manager and asked him to sell them some copies, which he did, at the same time keeping the money for his own use? What is our liability and what is our manager's liability?" In reply: Of course, you are responsible for the action of your manager. The only honourable thing you can do is to decline to execute the second order and at the same time refund the money paid to your employé. If the facts be as stated, you can prosecute the man for embezzlement.

VARIOUS QUERIES.—"OLD SUBSCRIBER" asks:—" (1) How are black vignettes obtained? Are they made inside or front of lens? (2) Have Bovril allotted prizes? (3) Are unpaid finished proofs—sent for inspection—secure from copyright? If copied and enlarged before we receive order and payment, and we register, can we recover damages on all printed?" In reply: (1) They are usually made by placing the mask inside the camera. (2) We do not know anything about it. (3) No, the copyright is vested in the sitter, although the photographer has not been paid for taking the portraits. The only remedy he has is to recover the amount of his account, for the work he has done, in the County Court.

TERMS OF AGREEMENT.—"C. B." says:—"I herewith send you a

copy of an agreement which my employer is desirous of having me sign. I feel rather dilatory about it, because I think it very arbitrary, with most abominable exactions. I shall be obliged to you if you will give me your brief opinion of it. Is it customary agreement couched in those terms?" In reply: We have read through the proposed agreement, and we may say it is about the most unreasonable and one-sided one we have seen. If you sign it you will be subject to month's notice, and will then be prohibited for an unlimited period from following your profession within a very wide area. We should certainly not advise you to sign any such agreement without due consideration. The copy has been returned to you.

BLACK SPOTS.—"T. S. H." writes:—"Can you explain why I occasionally get a fine crop of black spots on my P.O. prints? I wash before toning, and immediately on putting the prints into the toning bath, I see the spots. They are not regular in occurrence, but only occasionally happen, and have had them twice this last week. Ordinary town water is used and it is rather hard." In reply: The cause lies in small particles of iron rust, or some other metal being present in the water, and these adhere to the film and at once make themselves seen on being put into the gold bath—though they can frequently be seen before. The remedy is a very simple one, namely, to immerse the prints into a ten per cent. solution of common salt; this converts the whole of the free iron salts into chloride and the metal has no action on this.

REFLECTOR PAINT.—"FOREGATE" asks:—"I have just had a reflector made for my incandescent gas apparatus in my studio, but the white material, that has been put on the inside, is not white enough, also, is beginning to peel off. Can you tell what is usually used in such cases, and how applied?" In reply: Our correspondent fails to inform us as to the material of his reflector. It is extremely difficult to get an absolute white paint that will adhere, because the heat of the light tends to lift it. The most satisfactory white paint is precipitated calcium sulphate, and if the surface of the reflector, if of metal, be roughened by etching, and the sulphate be ground up with a little white dextrine and water, it will adhere fairly well and should it peel it can be at once renewed. It can, of course, be applied with a brush and stippled over so as to present a perfectly even appearance.

FACTORY ACT.—FORMULA.—"DON'T YOU KNOW" writes:—" (1) I should esteem it a favour if you will kindly advise me on the following:—In my business I am obliged to keep open up to 10.30 or 11 o'clock every night (week-days only) but do not start business until 2 o'clock in the afternoon, that is, work about half hour to three-quarters, about eight hours' work a day averages about forty-eight hours per week. I have a lad working with me who now leaves off at 8 o'clock, but he very much wishes to work with me until I close, viz., 10.30 or 11 o'clock. His work is in the dark room; his age is fifteen years. His working hours are not many, and it is entirely his own wish to stay. Am I allowed to keep him with me up to that hour without getting any permission from the Court, or, if I have to get permission, kindly let me know where I shall have to apply? (2) Kindly give me a formula for a very cheap and very rapid developer for snap-shot plates which are under-exposed, since solution only preferred, or No. 1 and No. 2 if same will keep a day without going black when mixed together. Rapidity is essential, and price a consideration. Will you make up about four gallons at a time and to last about one week (keep)." In reply: (1) We should advise you to consult the inspector under the Factory Acts for your district. He will supply you with all the desired information also with an abstract of the Act itself. (2) We should recommend a two-solution developer. The following will probably answer your purpose well:—Solution A: Metol, 40 grains; hydrochinone, 48 grains; sulphite of soda, 120 grains; water, 8 ounces. Solution B: Carbonate of potash, one ounce; water, one quart. For use, mix one part of A with three of B for ordinary exposures.

EX CATHEDRA.

Double Tone Carbon Tissue. A new carbon tissue has just been placed on the German market, which has two films superimposed, the upper one light colour, and the lower one a much darker tone of the same colour. It is obvious that by this means much darker shadows can be obtained, and it is claimed for the new paper that much better modelling and greater plasticity is obtainable than is possible with the old paper. There is no difference in the method of working it. The idea of a double-tone film was mooted by Henry Cooper in 1864, and was patented by J. R. Johnson in 1877, as recorded in our issues for the latter end of that year and the beginning of 1878, when there was a good deal of discussion on the point.

Portrait Painters and Photographic Portraitists. At Christie's auction sale of pictures on Saturday last, an unframed "Portrait of a Young Girl in White Dress," carrying a doll, by Geo. Romney, was sold for the substantial sum of £6,825 to the Messrs. Agnew. Now, there are probably no painter's works that portrait photographers could the better study than those by Romney, Vandyck, and Rembrandt. There are many who affect "Rembrandt" portraits that have not seen half a dozen examples of that great artist's work in their lives; some not even a single one. They simply light the portrait so that the major portion of the face is in shadow, and call it a "Rembrandt," while the result is no more like that old master's work than "chalk is like cheese." It is surprising how little interest photographers take in the portraits of the greatest painters, although

examples may be seen in all our public galleries. If they were more closely studied by them, we should see fewer of the—well, eccentricities, that we frequently meet with in photographic portraits.

* * *

Ultra-Violet Light and Eyesight.

One of our French contemporaries devoted to photo-mechanical progress, points out that there is a possible danger to the eyesight of operators in those studios which have recently been fitted up with the new arc lamps, in which carbon impregnated with metallic salts are used, so as to obtain a greater proportion of ultra-violet, or the photographically active rays, to the detriment of the visual. It is stated that in some studios the new lamps have been discarded and the old types replaced; in others, however, the new lamps have been found advantageous, but in both cases there is still the danger of injury to the eyesight of the operators, and that this takes a form analogous to the snow blindness met with on the Alps or other mountainous regions. Precisely the same precautions, it is claimed, should be taken, namely, the wearing of deep yellow or smoke-coloured goggles of a somewhat similar type to those employed by motorists.

* * *

Metric Photography.

M. Bertillon, the well-known director of the Anthropometric service of Paris, has just introduced a special system, full details of which are not yet to hand, under the above title, and which should be of considerable value in criminal photography for obtaining reliable data as to the size and disposition of objects at the scene of a crime, and would obviously also be useful for many other purposes, particularly in legal disputes, when a photograph is brought into evidence. We gather that the plate is impressed at the time of exposure with two scales, one showing the actual distance of an object, and the other the amount of reduction it has undergone, so that without any trigonometric or mathematical calculations the actual relative distances and heights of objects can be at once determined. He has devised a camera producing negatives in which the perspective is invariably identical. Each picture can, therefore, be compared at once with a given scale of distances and dimensions, provided the line of sight in the photograph be duly placed alongside a corresponding indication on the scale. On the other side of the photograph is another scale, that of dimensions. Obviously, the value of M. Bertillon's process entirely depends on the absolute accuracy of his instruments, and this requisite condition, he says, is mathematically fulfilled.

* * *

A Timely Warning.

A well-known correspondent has brought to our notice a particular effect, which may serve as a warning to others at this season, when low

temperatures are, or should be, prevalent. We may state that we were somewhat incredulous, but, having actually seen the test carried out, there is no question as to the facts. Some large negatives had to be reproduced, and for this purpose transparencies were made by contact, developed with a non-staining developer, and fixed, with the result that those portions which should have been bare glass, to use the familiar term, were stained a deep yellow. A fresh developer was tried, with like results; a fresh fixing-bath had been taken into use that morning, and it was quite clean, and therefore this could not have been the cause of the trouble. In taking out one of the transparencies, however, it was noted that the temperature of the fixing-bath was extremely low, and when tested proved to be only 40 deg. Fahrenheit. A portion of this bath was then heated to 65 deg. F., and a plate exposed and fixed in this, with the result of total disappearance of the stain. We tried this by exposing two quarter-plates in a stereoscopic camera, developing together, and fixing one in a hypo solution cooled to 38 deg. F. and the other in a bath at 60 deg. F., with precisely similar results. The cold fixing-bath gave a deep yellow stain, and the warm one perfect freedom from the same. The moral of this is obvious.

* * *

Blondlot's Rays. If die they must, the N-rays, so-called, will die hard, evidently. A short time ago we gave an abstract of Prof. R. W. Wood's investigations, appearing in "Nature," as to the reality of the alleged results in N-ray experiments, of apparently so convincing a nature, that it was difficult to imagine a rejoinder of any weight. Prof. Wood's letter was reprinted in the "Revue Scientifique" (No. 17), and in No. 18, the editor discussed the evidence. In No. 19 the opinions of Profs. Berthelot, Bonty, Pellat, Langevin, and Abraham are published. Prof. Langevin's opinions are the most emphatic. After making many experiments, he comes to the conclusion that whenever the experimenter does not know what phenomena to expect, the phenomena do not appear in the slightest degree. The consensus of opinion of the scientists named is to the effect that the results supposed to be seen or felt are wholly subjective, and due to suggestion, and in consequence interesting to the psychologist rather than the physicist. Yet, notwithstanding this formidable array of negationists, we have M. Blondlot a week or two later contributing to the Academy of Sciences, Paris, a paper on the photographic results of N-rays. The personal equation here being entirely absent, a photograph taken under proper conditions should be irrefragable evidence. The experiments described are a refinement on similar ones previously made, and M. Blondlot considers that they prove beyond cavil the action of the N-rays on the electric spark.

* * *

Some Notable Colour Prints. Probably we have by no means heard the last word with regard to colour-printing, and it is possible that in the next decade we may see some important advances in trichromatic printing, and even the adaptation of this to photogravure, but successful as have been the best of the three-colour prints at the present time, they have been very disappointing, and the very process does not lend itself to perfect reproduction because of the irritating cross-line screen. For some time Mr. Franz Hanfstaengel has issued individual prints, in photogravure in colours, and excellent as these have been they are entirely surpassed by the series, eleven prints, which are reproductions of the most beautiful canvases by Sir Joshua Reynolds in the possession of the Right Honourable the Earl of Spencer at Althorp House. The Althorp Reynolds's are, of course, famous, and in bygone

days we knew them well, and having had an opportunity of examining these reproductions we can only say that they are some of the best examples of colour-printing that have yet been turned out. It is possible, of course, to say that they do not in all cases, reproduce the effect of oil. This is true if closely examined, but when glazed and hung, we hardly think that in the majority of cases the charge can be maintained; the actual cracks and brush marks are faithfully reproduced, and the colours have softness and mellowness that we have not hitherto seen. Personally we cannot help expressing regret that they are only to be obtained in a complete set in portfolio, but obviously from the print collectors' point of view, and the fact that the present edition is to be limited to one hundred numbered impressions of each plate will make them all the more valuable.

* * *

Measuring Lens Curves. In the case of single simple lenses knowledge of the curvature is quite sufficient, given the refractive index, to enable the focus to be ascertained. Indeed, there is largely used by opticians an ingenious, simple instrument, which, applied to the surface of an eyeglass or spectacle lens, gives the focus of each surface to a fraction of a diopter, and without calculation, on a small dial, these glasses having an approximately uniform index. The manufacturers of large lenses, such as are used in photography, employ a still more delicate spherometer, by means of which he can take to a minute fraction of a thousandth of an inch the degree of curvature, and we apprehend that these instruments are employed in fabricating the cheap foreign imitations of English pattern high-class objectives. But when the question of the small lenses used in microscopes has to be considered, other methods have to be employed. At the last meeting of the Physical Society, Dr. C. V. Drysdale exhibited and described an apparatus for the direct determination of the curvatures of these small lenses. Parallel light from a distant source falls upon a plain unsilvered mirror—e.g., a plain sheet of glass, inclined at an angle of 45 deg. Some of the light is reflected, and brought to a focus, by an ordinary convex lens. The surface to be tested is placed at this point, and reflected rays proceed as if they had come from a point on the surface. They pass through the plate glass into a telescope focussed on parallel rays, and an observer sees an image of the distant source. If the surface is convex, and is brought near to the lens, thus, when it reaches such a position that the centre of curvature is at the focus of the rays emerging from the lens, the light will again retrace its former path, and a distinct image of the source will be seen in the telescope. In order to obtain the two images, the surface has, therefore, been moved through a distance equal to its radius of curvature. If the surface is concave it must be moved away from the lens.

* * *

The Power of Incandescent Electric Lamps. At a recent meeting of the Physical Society, Mr. G. B. Dyke contributed and read a paper on "The Practical Determination of the Mean Spherical Power of Incandescent and Arc Lamps."

As there must be thousands of incandescent lamps in use for every single arc lamp, it is obvious that the bulb type is the one to which most photographic interest will attach. The method adopted by Mr. Dyke was to set the lamp spinning at the rate of three hundred times a minute, so as to give a sort of average illumination, and then to measure the emitted light in various azimuths, step by step, and then obtain the mean spherical power. For a manufacturer's estimate, to show the total light produced by a given expenditure of current, this method is satisfactory enough.

for photographic purposes it is not very suitable. To obtain working data for photographic use, a knowledge of the power in various angles would be most useful. If we are required to know the power of the light from a dark room lantern, all would depend on the position of the light as to how much was received upon the plate, and its angle or azimuth. If the lamp were to be for supplying the well-known umbrella pattern of a series for studio use, a difference of efficiency amounting to ten or twenty, or more, per cent. might be brought about by varying the position of the lamp (which is very far from being analogous to a point of light set in the centre of a uniform globe). A knowledge of the range of emissive power would enable a suitable position to be chosen, and this would vary according to the type of globe employed. Again, the use of the incandescent globe in enlarging and copying is not by any means sufficiently known or adopted. If what might be termed a map of the power in various zones were supplied with the various lamps made, it would be most useful. For example, any one who has had experience with illuminating paper prints that are being copied knows that, quite apart from the question of annoying streaks of bright light, a slight turn of the lamp is capable of altering the illumination to such a great extent as to make an exposure vary in a ratio of ten to fifteen, and so on. We will hope some practical benefit may result from a consideration of Mr. Dyke's paper.

* * *

Resolution in Photo-micrography.

It is a well-established fact that the greatest resolution of the structure of minute objects with the aid of the microscope is only obtainable by the use of light of extremely short wave length, but this brings us into the violet ultra-violet region of the spectrum, to which the eye is not very sensitive, in micro-photography the second objection does not count, but the feeble intensity remains a drawback. Dr. A. Kohler, of Jena, has therefore tried ultra-violet light, notably the rays given out by electric sparks passing between cadmium electrodes. These rays, of wave-length 275μ , have a high intensity. Dr. Kohler described his new camera-microscope, which has been constructed by the Zeiss Glass Works, of Jena, before the Breslau meeting of the Naturforscher-Versammlung. The lenses of this microscope are made of crystal and of fused quartz; they need only be corrected for spherical aberration, because no chromatic aberration has to be guarded against when monochromatic light is used. As the ultra-violet light is invisible, however, an artificial eye has to be combined with the microscope for focussing and adjusting. This artificial eye consists of optical parts made of crystal, and of a retina made of fluorescent glass, which responds to ultra-violet rays. The observer examines through a lens the image thrown on this artificial retina. The instrument can, indeed, also be used for subjective vision by ultra-violet rays, and for this purpose magnesium light, of wave-length 280μ is still more suitable than the cadmium light. But the fluorescent light is injurious to the eye, and the finest detail can only be studied by photography. Yet the fluorescence helps in bringing out further detail. Dr. Kohler also examines his specimens—so far, mostly organic tissues—in a mixture of glycerin and water, or in salt solution, of which physiologists make large use. The ultra-violet rays once show differences in the structure, which, hitherto, had alone revealed. Thus the horny portions of the epidermis, the membranes of plant cells, and other parts, are more or less impermeable to ultra-violet rays, so that other advantages are realised in addition to the increased resolution. It would not be surprising if ultra-violet illumination should also render good service in metallography.

TRADES UNIONISM AMONGST PHOTOGRAPHERS.

THE reprint from the "Australian Photographic Journal" which we gave last week shows that the employees in New South Wales have combined, and have framed an Association amongst themselves which has been duly registered in the Industrial Arbitration Office at Sydney. On reading this agreement it will be seen that the Association is formed on strict trades-union lines, such as obtain in most of the trades unions in other trades in this country. Nearly every trade here has its union, even to the labourers and the navvies. A correspondent, in another column, suggests that a union of photographic employees should be formed in this country similar to that in New South Wales, and puts the question, that if this can be done there, why cannot it be done in the old country? This is by no means a new suggestion. It has been made several times, but that is all, and, as we all know, nothing has come of it. No one has come forward who has done more than suggest that the thing should be done, that it ought to be done, etc. But what is the good of suggestions if there are none who will assist in carrying them to a practical issue? Active work, and not mere talk that such-and-such things ought to be done, is what is required to form such a union as that in N.S.W. It seems to us that photographic assistants here have very little unity amongst themselves in working for their mutual benefit. Take, for example, the old Benevolent Society. It was notorious that very few of those for whose benefit it was formed subscribed to it, although the subscription was but half a crown a year, and took no interest whatever in the thing until they found themselves "stranded"; then they applied for relief from its funds. We notice in the N.S.W. Association that a minimum scale of wages is enforced for employees in every department, from apprentices upward, and that a certain time of apprenticeship is also stipulated—namely, for mounting, finishing, and spotting, including the care of the negative, it shall be two years. For retouching negatives it is three years. The term of apprenticeship for operating, developing, retouching, printing, and enlarging shall be for five years. There is a further stipulation as to the number of apprentices that may be taken in an establishment. It is limited to one apprentice and one junior to each senior assistant employed. In this country a very large proportion of photographic assistants have not served any apprenticeship at all; neither have many of their employers for that matter. For all that, many, although they do not really thoroughly understand the business themselves, do not scruple to take apprentices, of course, with a premium, and sometimes make as much out of them as out of their business, besides getting the services for nothing, or for quite nominal wage. In most of the trades unions here in other trades the serving of an apprenticeship is a *sine qua non* of membership. Is that likely to be the case if an assistants' trade union were formed in this country? This is a matter that will have to be taken into consideration by those who may attempt to form such a union—if any do. There is no question that an Association of Photographic Employees, particularly if it combines with it a benefit fund, is very desirable, and, if formed, it will have our best wishes for its success.

IN reference to our notice of Cubrome in our last issue, the special copper solution placed on the market by H. Edmund and Co., we would point out that in the case of plates they may be darkened by the application of a 10 per cent. solution of nitrate of silver, and that the same solution diluted may be applied to a bromide print, and that the nitric acid should be used after bleaching and before intensification.

PRESS PHOTOGRAPHY EXTRAORDINARY.

By AN OCCASIONAL CORRESPONDENT.

"THE Chinaman, as a mere man, is a shifty individual; but as a merchant a fair trader. The Japanese man is square, but in business dealings—watch him."

Such is the gist of oft-quoted advice in regard to dealing with Orientals, and during the current war more than one unfortunate photographer-correspondent has found that at least a part of the advice is well founded. The trouble dates from the beginning of the war. The opening incident was the sea fight at Chemulpo, where an American officer made a snapshot at the Russian gunboat "Korietz" as she blew up—or, rather, at the cloud of water and smoke which the explosion raised. A newspaper man heard of the exposure, and offered a fancy price for the film—before it had been developed. But the naval man thought he had something valuable, and declined to sell. Instead, he took it ashore to the local photographer for development. Unlucky speculation! The film was a complete failure. But next day the photographer was selling photographs of the explosion—fivepence each. "They were from another film; the one he had developed was a failure. He was supremely sorry." The naval man went ahead in the courts and proved his case. But what were nominal damages, compared with the fancy price which had been offered him? And the affair became a standing joke against him.

A great many films have been developed in Tokio, and the local photographers have shown a nice perception of what are good news pictures. Press agencies have sprung up there, and European and American papers have the cream of correspondents' work offered to them—before the correspondents themselves can submit it. Tokio knows all about mail boats and the quickest routes, and apparently Japan is not interested in copyright.

One correspondent never for a moment suspected why his pictures were twelve hours late. He was annoyed that he had missed the mail, but it was not until his home agent advised him that his pictures were a fortnight too late—having already reached the publishing offices through "another source"—that he discovered the perfidy of his bland little photographer.

In the latest of these little "beats" a correspondent has, on a conservative estimate, lost a cool hundred pounds, which amount has gone to a Japanese agency. They so manipulated matters that they "scooped" two continents. In one country they were ahead twelve hours only—but that was quite sufficient.

The only photographers who have received any adequate recompense for their pictures are those who took their own development outfit with them. It was no easy task to follow an army all day, and develop—under extraordinary difficulties—all night. But that is practically what some of them did in the early stages of the war, when interest was at white heat, and editors were clamorous for pictures. Those were the days of winter, and crude Korean houses had small facilities for warmth. More than one film was spoiled by the film suddenly becoming jammed as it was being turned slowly through the developing machine, and examination would reveal the developer as a mass of ice. But lots of good negatives were saved, and the photographer reaped his due reward.

The Japanese does not confine his genius to the appropriation of pictures. When Admiral Togo suddenly loomed into prominence his portrait was demanded. But the gallant admiral had never made the grand tour of the studios, and his presentment was not to be found. But what did that matter? The papers are constantly printing advertisements which warn us against other goods, which are represented as "just as good," and are pushed for the sake of the extra profit. But they were taken in over Togo, and a good many guineas were paid for portraits of some other estimable gentleman, of whom the world at large had never heard, and in whom it took not the slightest interest—that is, until it was labelled as "the gallant Admiral Togo."

THE IMPROVEMENT OF NEGATIVES

THE title of these notes is somewhat misleading because reproduced negative can hardly be said to be improved; yet as we propose to deal first with a particular method of improving negatives, the title is as it is.

It too often happens, particularly with work done in unaccustomed surroundings, or through errors in exposure, that a negative is obtained which may at first sight be said to be absolutely useless. For instance, when one has a subject such as an interior in which the contrasts of light and shade are abnormal or so great in the negative that to print out the high lights means blocking up the shadows, and obtaining details in the shadows means no detail in the denser portions, it is obvious that something must be done. The old devices of matt varnish, tissue paper, and crayon and a stump mean some manipulative skill which all do not possess.

In such a case we may use with good effect ammonium persulphate as the reducer, and it is well known that this reduces the high lights and not the shadows, and by this means we may obtain a far more even and harmonious result. Excellent as this method is, there are occasions when the reducer seems to make up its mind to play pranks, and spots and stains of various shapes and shades are obtained. An alternative method is an advantage.

The alternative which we would again call attention to is by no means new, but in the later and more advanced ideas now prevalent it seems to have somewhat dropped into disuse although extremely valuable. It was first suggested by Edgely in 1881, and the principle is merely the conversion of the metallic silver image into chloride of silver, and then redeveloping. Lately this has been revived as a method of intensification; but whilst it can be thus used, we would point out that it can be not only a method of intensification, but also a method of reduction at the same time, the shadows and most delicate half-tones being intensified, and the higher lights reduced in proportion.

The process is simple, and can be repeated *ad lib.* till a perfectly flat result may be obtained from even the most harsh negative. It will not, of course, make detail where there is none, but where there is the faintest trace of shadow detail it will intensify it.

The negative should be immersed in the following solution till bleached right through to the back:

Pure hydrochloric acid.....	10 parts.
Potassium bichromate	3 parts.
Alum	15 parts.
Water	450 parts.

It must now be thoroughly washed; too long washing seems almost impossible, for the bichromate is difficult to remove, and should any traces be left in the film, stains will subsequently appear.

When washed enough, a rather slow-acting developer—such as hydroquinone, without bromide or ferrous oxalate—may be used, and development continued till the critical point is reached; and this point can only be determined by continuous and careful scrutiny of the back, not the front, of the plate. Our practice is to immerse the negative in a hydroquinone developer till the surface reduction is distinctly apparent, and then lift the negative out of the tray, and, holding it face downwards, watch the developing action on the back, occasionally holding the plate just below the surface of the developer but face downwards. A point will now be reached when the shadow detail and the major portion of the half-tones will be blackened, but the higher lights and densest high lights will still show white. This is the critical point; one has now to have had some little experience to determine the particular moment to stop development, and this can at once be done by a rapid wash under the tap and refixing.

The result of this treatment will be apparent at once. The

whole of the image has been converted into silver chloride, and on development it would, if carried through, give a denser negative; but as development has only been allowed to continue till the shadows and half-tones are reduced and the high lights only partially so, then it is obvious that we have a flattening of the contrasts by the increase of the shadow detail and the production of the *in statu quo* of the high lights.

Obviously, then, if this is repeated a very great flattening of the whole scale is possible, and this method, if carefully carried out, enables one to considerably improve the printing qualities of the negative.

There is also another type of negative with which most of us are familiar—namely, one in which there is absolutely no contrast at all. It is as flat as it can be, and experience very soon shows us that intensification by any ordinary method is useless, for the differences of contrast between high light and shadow are so small that intensification of one means intensification of the other.

There are, of course certain printing-out and developing papers, by means of which this lack of contrast can be improved, but one does not always want to use a p.o.p. nor a particular development paper, and at any rate a negative that is of good printing contrasts generally is an advantage.

Professor Mach, of Prague, suggested some ten years ago that such a negative should be placed in optical contact with a mirror or sheet of opal glass, and copied through the back; but to avoid the reflection from the glass, which it is obviously impossible to do away with, he cemented a prism of low angle to the back of the negative. For such work as his namely, the photographing of flying bullets—such a course as this was permissible; but for the average worker, the process is entirely out of court, not only on account of trouble, but also cost. This, then, we may at once dismiss.

There is, however, the method of making a transparency, then a negative and repeating the cycle till a perfect, or, at least, a good printing negative is obtained, the idea being with each exposure to obtain increased contrast by slight under-exposure and the use of a hard-working emulsion. Now the hardest working plates are either pure chloride or chlorobromide emulsions, and by choosing one of these and slightly under-exposing and using a developer rich in bromide and a fairly prolonged development, after a short exposure, so as to obtain as great a contrast as possible, it is very easy to obtain a good printing negative from an absolutely useless one.

We know that there is some trouble and time involved in this process, but the end justifies the means, and, after all, the negative is but a means towards the end, which is the perfect print.

The mixing of flash-light powder caused an explosion in the establishment of a photographer at Toronto last month, and the whole place was completely wrecked, and the photographer himself seriously injured and burnt.

The toning of bromide prints by the hypo-alum process has often met with disappointment, and yet if properly handled is capable of yielding pleasing, in fact, beautiful browns and sepias. The Hull Society consider themselves fortunate in persuading one of its members, Mr. G. F. Bristow, jun., who has spent some years in producing his numerous and fine enlargements by this method. Three zinc dishes were kept going toning members' own work enlarged the previous Monday evening by the Society's lantern. Each one was stopped at the moment the owner desired the resulting picture to be in tone, and the demonstration proved most instructive and successful. The enlargements should be developed with the Imperial Hydroquinone formula, and a muddy black aimed for, when the best results are secured if taken considerably further than for simple black and white work. Take of hypo 8oz., water, 20oz.-12oz., alum, 2oz., water 20oz.-5oz., and water, 18oz., and place prints in cold and gradually heat until the finger can just bear it. Commence to tone in quarter of an hour.

STYLES: AN ANSWER TO VARIOUS QUERIES.

IN No. 2324 for November 18 a correspondent propounded some queries which, though answered briefly in the ordinary way, we thought of sufficient interest to go into more fully, as the queries dealt with the questions of styles. This is of ever-present interest to the profession, especially in the provinces, for frequently the man who can get hold of a new way of finishing photographs, or even one who makes a timely resurrection of an old fashion, stands a considerable chance of getting fresh business, and having a run on that particular line. Moreover, whilst the metropolitan professional can see and study any fresh idea that may be brought out, his less (?) fortunate brethren sometimes only see the particular fashion on a rare trip to town, or have it forcefully brought to their notice when it is used by a competitor perhaps three or four years after its inception in the capital. A case in point is the Cosway portrait mentioned by our correspondent. Whereas this style has been used in London for a good many years, in some of the northern towns it has only just made its appearance, and this owing to the placing on the market of the masks required by the Autotype Company.

Perhaps it will be as well if we first give a resumé of our correspondent's queries:—

"(1) I have a batch of prints to mount on art paper, C.C. plat., etc., and have met with the usual difficulty of cockling, even when dried under moderate pressure; I have tried thin gelatine and seccotine. Could you let me have a few practical hints? I have, of course, mounted them dry. (2) What are the most suitable subjects for the 'Romney' style of portraiture? Also could you give a brief outline of the style itself? (3) Re 'Cosway,' I have usually seen these with the head and shoulders draped. Is the draping necessary, providing the subject is suitable? (4) Where could I see specimens, or obtain a print of the above, and any other styles in vogue among the leading firms?"

The first question, though not actually one of styles, is closely related, since the most pressing fashion of the moment is mounting on paper mounts, not necessary multiple, but plate-marked thick rough brown, green, and other coloured mounts suitable chiefly for carbon prints or other positive-coloured images with a fairly rough surface, and also the very popular Japanese vellum. The latter is very thin, and with even the seccotine and gelatine mentioned, very prone to cockle.

These two mountants, or, rather, the mountant and the substitute, are both satisfactory in some cases. The gelatine, if made as given in the Almanac, will not cockle even medium thick mounts if applied in a thin streak round the edges only, and then the print placed under pressure. Seccotine sticks well, and in our hands does not cockle the thinnest mount if applied to the edges only as before. It, however, suffers from several defects, as all makeshifts not used for the particular purpose for which they were intended must do. The chemical constituents, whilst not harming carbon prints, cause a sort of fading with silver which may have been mounted with it. This stain, or whatever one likes to call it, only shows on the surface over those places to which the seccotine was applied at the back, so if one mounts these silver prints round the edge, one obtains, after a lapse of time, an unsightly border.

With carbons this is not apparent after some years, and for these the handy tubes are useful if one has nothing else on hand. For multiple mounting, i.e., several layers of paper, usually the number of layers in inverse ratio to your knowledge of the subject, this prepared adhesive is extremely useful. It sticks tenaciously after even a few seconds, whilst a couple of minutes is sufficient to hold it firm enough for more additions from the grocer's store. Only a dab at the corner is needed, we think, for the lower layers of paper. Having discussed the mountants mentioned, we beg leave to remark that there are several mountants specially made and which can be

obtained commercially, and which will not cockle a mount of ordinary thickness, and are perfectly harmless to even a silver print. Alcoholic solutions of certain resins may be used. These mountants only require placing in warm water for a few minutes before use, and if applied in the proper way they do not cockle even the thinnest of paper. The following instructions, of course, apply to any form of non-cockling solution:—

As dents, etc., in the prints do not disappear in the mounting as with starch, every care must be taken during the drying of the prints not to bend or otherwise mark them. When dry they will probably curl somewhat badly, and must be straightened. To do this take a sheet of perfectly clean paper and a straight-edge—a penny ruler will do if the edge is quite smooth. Now lay print face down on paper, and place edge of rule on back, pressing down with some force; now take edge of print in finger and thumb and pull from under rule. Repeat this in every direction until four corners turn outwards from face. If prints are now placed under a weight for an hour or so they will be found quite flat and ready to mount. To mount, cut a number of pieces of paper slightly larger than the prints to be operated upon, and of a number the same as the total number of prints. The mountant, having been placed in warm bath, and being in a fluid state, is ready for use. The mounting-brush should be a very small, stiff hog's-hair one. An ordinary very small house-painter brush is the kind we mean, and the hair should not have a greater diameter than a quarter of an inch. To stiffen up the brush, bind (or get a painter to do so) the hairs to within half an inch of the ends.

Having the mounts, mountant, and prints ready, the first print is placed face down on one of the cut papers, and a streak of mountant as narrow as possible is run round the outside edges within about a twelfth of an inch of the side. Of course this last measurement is not essential, and it does not signify a great deal if one does overstep the mark, but that is the point to aim at. If the print is held down in the middle with the fingers the nails sometimes make disfiguring dents. It is better to place a small glass cutting-shape (one with knob) in the middle and hold down with that. When this print is done take a fresh piece of the cut papers for every one, and no mountant will get on the face.

The prints are, of course, centred in the usual way. After mounting, place under a weight with blotting-paper over the surface of print for a few minutes. If anything goes wrong, a short soak in water will separate the print and mount. We have treated this subject at some length, not having much space for the subsequent questions, but our excuse must be the great number of queries we get on the subject of mounting on to paper.

We must confess we do not quite understand our correspondent's second question with regard to "Romney" portraits. If there are photographic portraits designated by this title we think it must have been applied somewhat arbitrarily, and is perhaps of only local significance. We hardly like that expression, "the most suitable subjects." It sounds too much like blind imitation of a picture rather than a proposal to study their composition, balance, and arrangement with a view to original work. Moreover, one must remember that the style and fashion of one century are not usually applicable to those of another. Our thoughts or ideas, as well as our costumes, have changed, and whilst the old-masters' method of handling and general treatment of line and mass will always be applicable to photography, though, of course, only in a moderate degree, knowledge of these things should be acquired so that we can the better express modern men and manners rather than for the sake of copying models and positions.

With reference to Romney's style, he is chiefly noted for his vigorous handling and the charm with which he infused his sitters, frequently charming in themselves in striking contra-

distinction to the modern cult of ugliness, which prizes the greatest, the most plain, models. Lady Hamilton was one of Romney's frequent sitters, and our querists cannot do better than study some of the photographic reproductions of her portraits.

The Cosway portrait, or, rather the photographic version, is, of course, an oval photograph in a sort of washed-in border in two or three shades of monochrome. The masks necessary for printing in this border round the masked one, oval, are now supplied commercially, and are negatives made from old engravings. We cannot find a great deal to cavil at in the name of this style, since portraits well done in this fashion in sepia, carbon, or platinotype bear a striking resemblance to old engravings. If the centre portion is made into a scene in tint, the *tout ensemble* is that of a mezzotint engraving, though imitation of another process may not benefit photography, and this sort of imitation is certainly not artistic yet in the eyes of the public it passes as such, and therefore should be practised. The draping is not absolutely necessary, of course, but it will be easily seen that the modern dress hardly agrees with the style of the print, and that if the engraving illusion is to be thoroughly kept up, the drapery dependent on no whim of fashion is the better to use. This drapery, or "drape," as it is called in American studios, comes in very useful for other portraits, when the sitter has no evening bodice handy or other suitable dress, for instance. It may be what the ladies call a large fichu, or merely a few yards of butter muslin. In any case, for ease in photography, it should be dyed cream.

The last query depends a great deal on the locality of the questioner and the firm he has in his immediate vicinity. For reproductions of the best firms, or, rather, the firms who are marvels at technical skill and wonderfully prolific in arrangement and artistic lines and poses, though lacking the true artistic feeling, see such papers as the "Sketch" and "The Bystander," where there are nearly always whole-page reproductions of the leading men. There are sometimes in the Society columns true pictures of leading Society beauties by such men as Hinstead and Bullingham, to mention only two out of the ever-increasing number of picture-making professionals. The wonderful work of Crooke and Moffat does not often appear in these papers, but will be found in such papers as "Photograms of the Year," as well as others of the greatest educational value by Furley Lewis, Frederick Hollyer, and others.

With regard to photographs by the firms, too. The Rotograph twopenny post-cards are, of course, bromides from the original negatives by Ellis and Walery, Biograph Studio, and others. Whilst some are not to be imitated, others are very fine technically, and the poses in nearly all are good.

There are other post-cards, too, in collotype which reproduce very finely many of the great pictures of the old masters, and form a very cheap and handy method of obtaining specimens of some of the best pictures for photographic study. The series we have especially in mind is the Woodbury series of post-cards. They, of course, do not come up to the fine photographures supplied by the art shops, which, if one intends to frame, are excellent. Best of all, however, in our mind, are the carbon reproductions now sold in such numbers, and so great is the variety that practically any picture can be obtained.

With these many and cheap reproductions about, we think no student should be at a loss for subjects to study, and if these lines have reminded some reader that he wants to study pictures, and has the means ready to hand, that will be something.

THE Christmas number of "The Weekly Press," from Christchurch, New Zealand, is again to hand this week, and it is, if anything, almost superior in appearance to previous issues. As an example of high-class half-tone blockmaking and printing it is very commendable, and there is many an English magazine that could take a lesson from these fifty pages so crammed with good illustrations.

SOME NEW RESULTS WITH RESPECT TO THE PRINCIPLE OF THE CONSERVATION OF ENERGY.

II.

We have now to state the limitations of the principle (6), or

$$T - U = \text{const.}$$

Any problem of mechanics (i.e., any questions relating to the motion of masses under any of these circumstances of motion which we call "forces") can be put into equations, and is thus at least theoretically soluble (i.e., we know there is a solution, and only one, if the problem is completely stated, but we may not always be able to exactly express this solution in terms of known functions). The simplest way of writing these equations is a method due to d'Alembert and Lagrange, but it is to be remembered that this "d'Alembert's principle" is only a convenient way of stating what was already known in Newton's laws. These laws, in fact, supply a sufficient foundation for the whole of mechanics.*

From the equation embodying d'Alembert's principle, Lagrange derived a highly important and convenient set of equations which completely determine the motion of the whole mechanical system in terms only of T and U , when these are expressed in terms of those quantities ("generalised co-ordinates") which suffice to completely fix the position of the system in space. If this system is a rigid body of any shape and size, it is not difficult to see that six such quantities only are required (these may be the distances of its centre of gravity to three mutually perpendicular planes fixed in space—the "co-ordinate planes"—and three angles between certain planes fixed in the body and certain others fixed in space, whose fixity prevents rotation about any axis passing through the above point).

Now 6 is deducible from these equations under certain restrictions,† but not inversely. Hence the insufficiency of (6) alone to determine the motion of the system, an insufficiency which also follows at once from the consideration at the end of the note below. This remark is important in view of the fact that it is disregarded by Mr. Herbert Spencer, and hence many of the doctrines of his "Synthetic Philosophy" have been exposed by Professor Ward.‡

Although thus (6) is a principle of such small power—even if it is applicable—in most questions of mechanics, it possesses the important property of holding in some cases where even Lagrange's equations fail. That Lagrange's equations do not apply in certain cases of rolling motion (when bodies roll, without slipping) had been known since 1873; in 1899 M. Appell, of the French Academy, gave some new equations, which can take the place of Lagrange's without being subject to the failures of the latter; in 1902 I found, independently, and in quite another way, the same equations, and in 1904 I developed the theory of the equations, which are extensions of (or not failing) Lagrange's equations, in which paper is the detailed proof that (6) can hold even when Lagrange's equations

fail. This result is of some importance when we consider the possibility of a "science of energetics"; but first we must show how (6) has grown so as to express a quantitative connection between all branches of physics; in other words, has grown into the principle of the conservation of energy.

Let us consider, again, the equation (5). The "work" of raising a mass m to a height h against the (practically constant and $= mg$) force of gravity is mgh ; when it falls through the height h from rest the final velocity (v) is given by

$$\frac{1}{2}mv^2 = mgh,$$

and inversely if m starts with this v it will attain a height h .* The equation (7) states the equivalence of work and kinetic energy. In general, when the forces and conditions are subject to the restriction referred to before, we

$$T - U = \text{constant},$$

or, since the work (U) only depends on the positions of the masses forming the system, the kinetic energy (T) of the whole system (the sum of the kinetic energies of all the masses) is the same for two similar positions, whatever the paths and velocities of the masses may have been in the interval of time between these two positions. Let us, finally, think of our mass in (7), when at rest (its velocity $= 0$) at the height h (as it is for an instant) as possessing, in virtue of its position, the capability, or "potential energy," to produce the kinetic energy $\frac{1}{2}mv^2$ by falling. Then the potential energy (v) $= (-U)$, or, in general,

$$T + V$$

is a constant quantity for every position of m ; the lower m is (in one instance) the greater is T and the less is V , and vice-versa.

If the body m does not fall freely, but in gradually sinking heats another body or renders it electric in some sense, the heat or electricity produced must stand for exactly as much as the lost T , for the reason that if the heat produced "stands for" a greater (or less) quantity of work than mgh , it is (at least, theoretically) possible to arrange a mechanism to produce work—mechanical or otherwise—out of nothing; we shall have solved the so-called "perpetual motion." This argument was first used by S. Carnot,† who also said, in further explanation: "One will, perhaps, object that the perpetual motion, proved to be impossible by mere mechanical actions, is not, perhaps, so when one uses the influence of heat or electricity; but can one conceive the phenomena of heat and of electricity as due to anything else than to certain movements of bodies, and as such ought they not to be subject to the general laws of mechanics?" Also Helmholtz, in his celebrated memoir of 1847, following Carnot's example, also started from "the supposition that it is impossible to continually create moving force from nothing by any combination of natural bodies"; but went further, and carried this principle through all branches of physics. Helmholtz's memoir‡ thus contains a statement of the conservation of energy, though only as a (probable) hypothesis, and subsequent to the work of Mayer and Joule. The work of the latter is included under the more suitable title of "The Conceptions of Physics." PHILIP E. B. JOURDAIN.

* See Mach, *op. cit.*, pp. 293-305, 362-374, 495-509. Cf. also the section on the theorem of vis viva, pp. 374-381.

† For mathematical readers I put these in a note. They are (1) that the connection of the systems do not vary with the time (e.g., two masses in motion connected by a rod varying in length through heat); (2) that the integral expressing the "work" be an integral of a total differential of V , and V does not vary with the time; cf. Mach, *op. cit.*, pp. 507-508. Then (3) is a first integral of Lagrange's equations, i.e., if there are n Lagrange's equations, we require $2n$ integrals (in general) to solve the problem, (4) gives one.

THE INTERNATIONAL PHOTOGRAPHIC SURVEY OF THE HEAVENS.

[A lecture delivered before the Literary and Scientific and Natural History Societies, Reading.]

It was more than fifty years ago that photography came to the aid of astronomy, first in relation to the moon and then, in 1860, to the sun. The work went on slowly for some twenty years. Between 1876 and 1879, about 900 plates of the moon were taken at the University Observatory, and this was almost the last astronomical use made of the wet collodion plate. In 1882 there was a very bright comet, that will not be seen again for 600 years, very low down in the southern sky. Its appearance attracted the attention of a photographer at the Cape, and he tried to photograph it with a dry gelatine plate, with an ordinary apparatus resting upon the earth. The result was not very satisfactory, but the photographer took the photograph to Sir David Gill, at the Cape Observatory. After inspecting it, he invited the photographer to take his camera to the Observatory and strap it on to the tube of a telescope provided with a driving clock for the purpose of counteracting the earth's motion, which secured that the plate pointed to the same place during the exposure. Not only was the comet successfully photographed, but Sir David saw that a large number of stars had also been included. Copies of the photograph were distributed among astronomers in all parts of the world, and the dry plates came rapidly into use. This was the initial idea that eventually resulted in the International Survey. Dr. Common in this country quickly appreciated the advantage that might be derived by substituting the photographic plate for tedious and laborious eye work, and by 1883 had secured some fine photographs of the great nebulae in Orion and the Pleiades cluster. The immense amount of detail obtained with comparative ease with one hour's exposure far surpassed what had less accurately taken months and years to secure by eye observation. As an outcome of this work, an international conference was held at Paris in 1887 to consider the advisability of obtaining by photography a complete chart of the sky. It was soon apparent that such a piece of work, on account of its magnitude and the impossibility of the northern sky being seen at southern observatories, would have to be divided among several. The question was discussed generally and details reserved for a second conference, which was held at Paris in 1889, and largely attended by delegates from the most important countries in the world. Eighteen observatories had then agreed to share the work, six of which were in the British Empire, while the United States, with its 165 observatories and large means, did nothing for the scheme. All details were arranged at the conference. It was decided that a refractor telescope should be used, consisting of one flint and one crown lens, and so arranged that the plate should be placed at the blue violet portion of the spectrum instead of the yellow, as is usual. This was necessary because, while the rapid gelatine plate is not sensitive to the yellow rays, it is very sensitive to the blue. The lenses had to be specially constructed for photographic work, and the plates made of plate glass, which involved great expense, ordinary glass being too uneven and rough. It was decided to include stars to the eleventh magnitude, and to secure these it was found necessary by experiment to expose the plate for three minutes. Considering the small point of light that such stars presented, it was remarkable that so faint an object should leave its image in so short a time. Such, however, it did on a normally fine night, but it was agreed that each plate should be exposed for six minutes, three minutes, and twenty seconds. By this method dust marks or flaws were eliminated. Measures were also taken to prevent the distortion of the film. Besides those short exposures or catalogue plates, as they are conveniently called, it was decided that the whole area should be again photographed with an exposure of 40 minutes, these plates to be ultimately reproduced as charts or maps. To carry out these various decisions it was estimated a period of 25 years would be necessary, and that about 1,200 plates would require to be taken by each observatory participating. The number actually allotted varied from 1,060 to 1,512 plates, those in the southern hemisphere having a larger number. At Oxford they had 1,180 to cover their zone, extending eight degrees north of the Pleiades. The lecturer entered at some detail into the cost of the undertaking. At Oxford the necessary equipment was the munificent gift of Dr. Warren de la Rue, and the University had made an annual grant for the work. In France the Government had agreed

to bear the cost of the reproduction of the chart plates by photogravure. If it were carried out on the same scale throughout the world, the cost would be enormous. But observatories which were not subsidised by their Governments would not do the chart portion of the survey on this expensive scale, not only on account of lack of money, but also because of the small utility of the work, the sky having been many times covered, and being still covered, just as adequately for the detection of changes at Harvard University and by various people using lenses that cover the sky much more rapidly. For this reason they were not taking the chart plates at Oxford. The lecturer described in detail the methods of measurements adopted, and, to give some idea of the magnitude of the undertaking, he stated that he had found that the average number of star images measured on each plate amounts to 339, varying from less than 100 to just under 5,000, in a three minutes' exposure. Each plate is measured twice, giving with revision about 825 images, making at Oxford a total of star images measured of well over a million. The number of separate stars in this portion of the sky is about a quarter of a million in a band eight degrees wide. This, if regarded as typical, would mean some four million stars to the eleventh magnitude for the whole of the heavens, but probably this average would not be reached. One point of interest the survey had been able to determine was the varying density of the stars in the heavens. This varied upon the Oxford plates from about 120 to 776, or fully 6½ times the densest. At Greenwich the number varied from 200 to 600, or only three times, and the number of stars per square degree passed from 35 up to well over 100 at Oxford. One important use to which the catalogue plates might be turned was the discovery of new or variable stars. One interesting discovery of this nature had been made by Professor Turner in a plate exposed by the lecturer. This plate had been rejected as an error made in pointing the telescope to the sky, an error actually due to the star itself, which was mistaken for another near thereto. He had had the star under observation for ten minutes, eight days before the Professor had detected its true character. When the result was announced the Harvard University turned up a photo, taken two days previously, and upon it discovered the same star. It was quite probable that they had many undetected new and variable stars, and even minor planets upon their plates, but other more pressing matters had prevented them as yet being looked for.

The lecture was illustrated by a series of some 60 lantern slides, mostly of the lecturer's own preparation.

F. A. BELLAMY, M.A., F.R.A.S.

ROYAL INSTITUTION.—The following are the lecture arrangements at the Royal Institution before Easter:—A Christmas course of lectures (experimentally illustrated and adapted to a juvenile auditory), on "Ancient and Modern Methods of Measuring Time," by Mr. Henry Cunyngame; Professor L. C. Miall, Fullerian Professor of Physiology, R.I., six lectures on "Adaptation and History in the Structure and Life of Animals"; Professor Karl Pearson, three lectures on "Some Recent Biometric Studies"; Professor W. E. Dalby, two lectures on "Engineering"; Mr. A. H. Savage Landor, two lectures on "Exploration in the Philippines"; Mr. Churton Collins, two lectures on (I.) "The Religion of Shakespeare," (II.) "The Philosophy and Significance of 'The Tempest'"; Professor W. Schlich, two lectures on "Forestry in the British Empire"; Mr. J. J. H. Teall, two lectures on "Recent Work of the Geological Survey"; Professor H. H. Turner, three lectures on "Recent Astronomical Progress"; Professor R. Meldola, two lectures on "Synthetic Chemistry" (experimental); Sir Alexander Mackenzie, three lectures on the "Bohemian School of Music" (with musical illustrations); Mr. D. G. Hogarth, two lectures on "Archeology"; Professor J. J. Thomson, three lectures on "Electrical Properties of Radioactive Substances"; and the Right Hon. Lord Rayleigh, three lectures on "Some Controverted Questions of Optics." The Friday evening meetings will begin on January 20, when a discourse will be delivered by Professor Sir James Dewar on "New Low Temperature Phenomena"; succeeding discourses will probably be given by Dr. E. A. Wilson, Mr. Cecil Smith, Mr. J. W. Gordon, Professor H. Marshall Ward, Chevalier G. Marconi, Professor J. J. Thomson, Sir Squire Bancroft, Professor G. H. Bryan, Professor J. Wright, Professor J. C. Allbutt, the Right Hon. Lord Rayleigh, and other gentlemen.

SUN'S: THEIR VARIOUS STAGES OF DEVELOPMENT AS REVEALED BY THE SPECTROSCOPE.

[From the "Journal of the Camera Club,"]

THE lecturer apologised for the abstruseness of his subject. It was to him, he said, a most engrossing one, and one which had occupied him for very many years. Some time before he lectured to the members on the subject of Nebulæ, and he intended to take up the thread of his argument from where he let it fall and speak of the next stage to Nebulæ in star condensation and development.

The first slide showed a plain spectrum representing the dispersion of one small line of light. All the various rays of which the light was composed were bent out of their path on passing through the spectroscope, and their dispersion took the form of the coloured band shown. The light of any incandescent solid substance, similarly treated, gave a like band of colour. The hotter the source of light the more extended would be the spectrum at its violet end.

When the spectroscope was pointed to the sun a very extraordinary view was presented. Curious black lines appeared in the spectrum, in some cases crowded together, in others wider apart; in others again very fine or double. For a long time the meaning of these dark lines running transversely across the solar spectrum remained a mystery. Fraunhofer, with a tiny object prism, first discovered their existence in 1823. This pioneer work with this prism only saw a few of the lines at first, the remainder being unnoticed owing to the inadequacy of his apparatus; subsequently, with the aid of a four-inch telescope and a prism set suitably before it, a larger number of lines were discovered by him.

A mass of incandescent hydrogen glowing in its own light gives through the spectroscope only four lines—red, bluish-green, blue, and violet—instead of a continuous band of colour. These lines always had the same fixed position in the spectrum, and the same width and intensity. Sodium was represented only by the well-known double D line in the yellow, while the complicated spectrum of iron, on the other hand, had some 460 lines, ranging from red to blue. So it was with every element. Each had certain definite lines applicable to its own spectrum. The spectroscope thus furnished a means of identifying the elements beyond doubt. In 1859 Kirchhoff found that many of the bright lines of incandescent metals had their exact counterpart, both in regard to position and width, in the dark lines of the solar spectrum. These dark lines showed where absorption took place through vapours of metals and gases.

Kirchhoff made his first experiments with the two yellow lines of sodium because these were so easy to produce. As a matter of fact, it was so difficult to get rid of the sodium spectrum in the ordinary laboratory that it was something of a nuisance. In order to reproduce the two black lines found in the sun's spectrum, Kirchhoff took an iron tube five feet long, closed it at each end with a piece of plate glass; along the interior of this tube he placed small and absolutely clean fragments of sodium metal, and exposed the whole to the heat of a furnace. Thus he obtained sodium gas. He then placed at one end an electric light and a spectroscope at the other, and threw the electric light through the tube. As a result, instead of the two yellow lines of sodium, he got two black lines, superposed on the coloured spectrum of the electric light, and when he came to compare these with the two black lines in the same position in the sun's spectrum he found them to be absolutely identical. Thus he was convinced that sodium was in the sun's chromosphere.

Then followed the identification of various other elements in our luminary by the same process. It was now known that the black lines in the sun's spectrum were due to magnesium, iron, calcium, nickel, aluminium, sodium, helium, hydrogen, and various other metals and gases common to our own planet. To a great extent the constitution of our sun was known to us. It was composed of a central glowing mass, which represented the electric light of Kirchhoff's experiment; this was surrounded by an atmosphere consisting of incandescent gases of the various metals, etc., beyond that an atmosphere of hydrogen, higher still one of helium, and at the furthest the corona, which was probably the true solar atmosphere, and lay outside the region of the coloured prominences.

In reply to a question from one of the members, the lecturer further explained that the sodium in the sun's outer envelope was in a state of incandescence, without which the lines could not be obtained.

Were the sodium solid it would merely give in the spectrum a colour band. In this connection a very pretty experiment might be tried. A tiny piece of sodium should be placed in a test tube and heated with an ordinary Bunsen burner; the sodium gas which would be given off if placed in front of a spectroscope would give the two yellow lines. Examined, while still hot, with a good petroleum lamp behind it, a curious reversal would be noted: the sodium would have cut out its own light, and produced two black bands superposed on the coloured spectrum of the petroleum lamp.

Huggins, Rutherford, and Secchi followed in the steps of Kirchhoff. Secchi applied the spectroscope to the whole of the heavens, and discovered that while the planets gave the same spectrum as the sun (necessarily so, because they shone by its light), the fixed stars revealed a different order of things. The spectra of the stars differed from one another very considerably. Some were crowded with lines, others had very few lines indeed. It was found possible, however, to divide the stars into four types. The first type, the Sirian stars, consisted of those having one or two broad lines. The second, the Solar stars, resembled our own sun, and had a number of well-defined lines. The third consisted of those stars which had a number of lines crowded together and with peculiar "flutings" sharply cut off at the blue and shaded at the red end. The fourth gave a very faint spectrum consisting of a number of dark lines with flutings sharply cut off at the red end and shaded at the blue. All being suns in different stages of development.

In order to assist in tracing the earliest defined stage in the development of stars from Nebulæ, the lecturer showed a photograph of the Pleiades, in which group there were but seven stars visible to the naked eye. The photograph, taken with a very long exposure on different nights, revealed 1,421 countable stars; another, with a longer exposure still, showed that nebulæ surrounded the principal of these orbs. It was only photography that revealed these nebulous structures; when observed under ordinary conditions no nebulæ were visible. The long exposure impressed them on the plate, and these stars had been as it were "caught in the act" of condensing.

The lecturer also showed a field of star spectra. Each star was seen simply as a spectrum, owing to the fact that there was a large prism before the objective which dispersed the light into spectra. These spectra greatly differed from one another, again illustrating the various stages in development in the fixed stars. Some were young, others a little older, others again old.

The first type of star to be noted was that in which the metal lines were so faint as to be all but invisible. In this type hydrogen was so prominent and intense as to overpower almost every metal that was present. At the same time it was not present in equal force in all the "white stars." In the case of Sirius one had practically only the G line and the H line. There were, indeed, other lines of a very faint character, but hydrogen was overwhelmingly prominent. Another peculiarity in stars of this type was that the violet portion of their spectrum was very intense and prolonged, showing that the heat was very intense. The spectrum entirely differed from that of our sun. These were, in fact, the white stars of the heavens representing the first definite form after condensation from nebulæ, an atmosphere of hydrogen and helium surrounding them to an enormous extent.

The second or solar order of stars consisted of those in which the metal lines were similar to those of our own sun, the typical star being Capella. In these also the hydrogen lines were prominent, but condensation and cooling had gone on to such a degree as to make the dark lines of numerous metals and gases distinctly visible. In α Procyon, for example, the majority of the lines traceable were due to iron, calcium, magnesium, sodium, nickel, cobalt, barium, etc., lines are also present, those of hydrogen being prominent.

In the third class of stars, the hydrogen lines, instead of being black as hitherto, were bright; that is, coloured, as would be the case when examining incandescent hydrogen in the laboratory. This type of star, as a rule, was variable. At one time it would be brightly, and then would dwindle down until it nearly passed sight, when it would again revive and become bright. The thesis explaining the condition of these stars is somewhat at New York. The star itself had a small nucleus, but its atmosphere, it was shown that the light from the incandescent hydrogen, overpowered the dark lines emitted by the nuclei.

of this central nucleus would, therefore, be superposed upon the spectrum emitted by the whole of the atmosphere, and, as a result, the atmosphere being incandescent and more powerful than the nucleus, its bright lines were seen instead of dark lines, those of the nucleus being dark. There are, however, other explanations of the phenomenon.

The spectrum given by this third order of stars was similar to that of a sun spot. The lecturer exhibited a slide showing an outburst of hydrogen from the sun's disc as seen at the time of an eclipse. This upshot of hydrogen, when contrasted with the size of our own planet, was seen to be truly enormous. A photograph taken at Greenwich of the great sun spot of September, 1903, was also shown. This spot extended over very nearly five-millionths of the sun's disc. It was supposed that these spots were uprushes from the atmosphere of the sun forming glowing clouds of vapour in the outermost solar envelope. Examined through the spectroscope, it was found that some of these were clouds of magnesium, others of sodium, etc., and that they generally had small bridges of incandescent hydrogen connecting their darkest portions. The two narrow sodium lines in this spectrum were found to be greatly thickened, showing that the pressure was very great.

The lecturer entered somewhat minutely upon the star Beta Lyrae, to the south of Vega. This was a variable star, taking 12 days, 21 hours, 47 minutes, and 13 seconds in which to accomplish its cycle. Its two maxima and two minima changes went on with unalterable regularity. By means of a slide, prepared at Stoneyhurst Observatory, illustrating the changes in this star's spectrum for each day of the above specified period, it was seen that some of the lines performed extraordinary caprices. When the various spectra were compared with the time of the variability of the star it was found that they tallied to a considerable extent. There were a number of explanations to account for these changes. It was known that there were at least three sources of light—an incandescent gas giving off light of its own, and two further sources of light giving off two series of dark lines; but at another stage in this star's changes it was evident from its spectrum that there must be either four sources of light or that the same two series of dark lines must be superposed on a considerably widened bright line. The general opinion favoured the latter explanation.

The reason for the widening of the line might be illustrated by the case of a train travelling in the direction of the observer; if the light of its lantern were examined through the spectroscope it would be found that the advance of the engine caused the wavelength to shorten and all the rays to shift to the violet. If, on the other hand, the train were going from the observer, all the rays would be shifted to the red, and the light waves would be lengthened. Light waves were closely allied to sound waves, in which the same principle was at work. As a train approached the observer the sound of its whistle would rise in pitch; as it went from him the sound would lower in pitch. The sound waves shortened as the train approached and lengthened as the train receded. By the shifting of the lines it was possible to estimate the velocity of a star in the line of sight; when the lines shifted to the violet end it was known that they were being shortened, and by calculating this shortening of the wave length they could tell the pace at which the star was moving.

This category of events made visible by the agency of the spectroscope showed that the various components of this star were in a state of very rapid motion. Calculating by means of the two edges of the F line, a certain great scientist had estimated that the pace at which it was moving towards us was 68 kilometres per second of time. He further calculated that the circumference of the orbit was 74 million kilometres, and the distance of the centre of gravity 24 million kilometres. By comparing the spectra of this star in its various stages it was possible to learn the metals of which it was composed. The general idea now was that there were four suns revolving round each other, their eclipse and re-eclipse giving the appearance of these lines. A great deal more scientific work would have to be done, however, before the vagaries of this spectrum could be explained.

Order of stars to which the lecturer called attention included the Pleiades. These were temporary or occasional. They were few and far between, but stars sometimes blazed up in the heavens and were not usually seen there. Their sudden transformation

into the first magnitude would occasionally take place in twenty-four hours. *Nova Persei* was an example of this class. Ten days before this star appeared, in December, 1891, a photograph was taken of Perseus which gave no sign of anything remarkable; in less than twenty-four hours it came up from nothing to the first magnitude, out-rivalling Capella in brilliancy. Its spectra varied greatly, and even while one spectrum was being photographed the motion in the line of sight shifted the lines. An enormous region of nebulous gas many millions of miles in extent evidently surrounded the star. During its continuance as a first magnitude star, hydrogen and helium shone out in its spectrum with enormous intensity. After a time it dwindled down to the third or fourth magnitude. In the course of three days it shifted from the third to the fifth and back again to the third. The change in the H line was so enormous as to show a motion in the line of sight of from 500 to 700 miles per second. The vortices, the storms, the hurricanes that occurred as shown by the different intensities in the hydrogen lines must have been beyond the power of any adjective to describe. Various explanations were put forward to account for the phenomenon. A solar system like our own might have been precipitated into a nebula. This was more likely than the alternative explanation, namely, that a very large body had crashed into a faint star; in any case, for such an enormous mass of gas to develop in twenty-four hours the upheaval must have been truly awful, and the terrific motions and forces which were raging must have been appalling.

In order to show how the mass of gas could extend far beyond the nucleus of a star, the lecturer placed on the screen a photograph of this Nova surrounded by a nebula. He also showed the spectrum of the great nebula of Orion and the trapezium stars, and pointed out how the beginning of the development of a star out of the nebula itself was to be traced.

To sum up the whole, all the stars were suns, and were different in constitution only because of their different stages of development from nebulae. They might be classified according to the gradual cooling which had taken place, as white, yellow, red, and orange, and they ranged from the brightest, identified by the hydrogen lines, and few or no lines to those of the lowest group giving a very faint spectrum with crowded lines. In all of them were the same elements as in our own sun, and all of them had their part in the one grand development of the enormous universe.

In 4,334 stars of a magnitude only down to the fifth, 73 per cent were white stars (2 per cent. of these having broad lines in the spectrum); 25 per cent. were suns like our own; and 1 per cent. were cold or cooling stars which would go out of light altogether so far as the spectroscope was concerned.

This science was still in its infancy, and this was an age of new developments. He felt confident that in a hundred years' time the astronomer would be in a much better position to talk to the members of the Camera Club about the wonders of the universe.

J. A. FORMOY, F.R.A.S.

At a well-attended meeting of the Bolton Amateur Photographic Society, on the 30th ult., at which the chair was taken by Mr. G. Hodges, the society's president, a most interesting and helpful lecture on "Architectural Photography" was delivered by Mr. W. A. McLean, the president of the Blackburn Photographic Society. In the course of his introductory remarks, after dealing with the questions of apparatus and materials, the lecturer touched upon some of the difficulties which beset the beginner in this particular branch of the art, and pointed out a variety of ways in which they may be met. A fine selection of slides, chiefly from Mr. McLean's own negatives, were next exhibited, the lecturer, who possesses a fund of racy humour, recounting the circumstances under which some of the exposures were made and pointing out their peculiarities, technical and otherwise. The usual vote of thanks terminated a meeting, which may be said to augur well for the success of the ensuing session. The society, which is in a flourishing condition, offers many advantages to amateur photographers, particulars of which may be obtained on application from the secretary, Mr. A. Robinson, of 2, Fold Street, Bolton.

OLD CUSTOMS IN ENGLAND.

[Abstract of a lecture delivered before the Walsall Literary Institute by Sir Benjamin Stone, M.P.]

Photography had only been the auxiliary helper towards the end he had in view, and that was recording the current history of their national life, and, though his collection was large and varied, as it should be to reflect the national life of the country, yet there were special collections of pictures which were more or less interesting in groups, and on this occasion he would like to use the group he had got together of the National Customs of England which survived in various parts of the country. They must understand that throughout the country there were a very large number of old customs that were still kept up, sometimes in cities, sometimes in country villages, and which were extremely interesting in themselves, but were really little understood by people, even by those taking part in them. They were looked upon as annual and interesting festivals, but the meaning of which the people who took part in them had not the remotest idea, and yet that meaning was very significant and most interesting, and would afford a subject for his address that night, an address which he hoped they would, when he had finished, understand and appreciate. Many of these customs threw a light on the former history and habits of the people. These customs, which were very popular in ancient times, had survived until the present day in many cases. Some of them were religious customs, but many also, especially those which were kept up in country villages, were of pagan origin. Other customs had arisen out of the grant of Royal Charters, by which certain privileges had been granted in different parts, all of which had given rise to certain festivals and customs that were very interesting, if one visited them, and knew the reason why they existed. For instance, there were certain holidays and festivals, such as May Day, the Easter Festival, and Christmas, which had a distinct meaning. Some of the ancient religious festivals had rather got into disuse, but they still remained in different parts of the country. If they were well up in history, they might remember having read of one festival which at one time was very popular and universal in the country, and that was the Hock Tide Festival, which, as a matter of fact, commemorated the massacre of the Danes by King Ethelred and his Queen Emma. At the time that took place the Danish invaders had settled down amongst the people of the country, and had almost become part of the nation, but King Ethelred and his wife decided to massacre them, and this was done on the occasion of their marriage festivities, the slaughter commencing at Winchester, where they were married. Women also took a large share in the massacre. The rejoicings of Hock Tide were really to celebrate that massacre, although that was not known by many people in these days. The festival was still carried out at Hungerford, in Hertfordshire, on the Easter Tuesday, when the ceremonies were very quaint and interesting. After describing the various formalities observed, Sir Benjamin went on to speak more particularly of the custom of appointing two men at the festival to kiss all the girls. When he was last in Hungerford he said there was a difficulty, as the young men appointed had objected to carrying out their duties, but the ladies had risen in indignation. There was up till recently in Staffordshire still a trace of the old Hock Tide Festival in the custom of Heaving Monday or Heaving Tuesday, which he believed still obtained in some parts of the country. There were, however, few people, he thought, who connected that rather vulgar practice with the massacre of the Danes in the time of King Ethelred. In olden times it was the duty of towns and cities and even private people, according to the amount of income, to provide a certain amount of defensive armour and protection in case of war, and in the time of Edward IV. there was an Act passed requiring every town to provide so many coats of mail and so many halberds, and he believed that in Walsall they still had some of those venerable halberds, which, under that Act, they had been compelled to provide. More than that, in the neighbouring town of Lichfield, the Court of Aray, which was really the court held for the inspection of the weapons provided, was still carried out, and they still had there some of the original coats of mail. The fact that these had now to be worn by boys and youths and were too small for men might, he thought, be attributed to the fact that they were supplied soon after the Wars of the Roses, when most of the men had been killed off. The Bower at Lichfield was indeed one of the most

interesting relics in the country. The remainder of the address was illustrated with photographic slides, of which a large number of interesting ones were shown. Sir Benjamin explained the different customs, and showed that many of them had their origin in remote antiquity, such as the kern baby, whose origin was the Grecian festival in honour of the Goddess Ceres, and to Greece the custom was probably brought from Egypt. Amongst others which were shown on the screen were the festivals at Hungerford and Lichfield; the horn dance at Abbots Bromley, held originally to commemorate the relaxing of the arbitrary forest laws in the time of Henry II.; the morris dancers at Knutsford, Cheshire, from which dances had come the present-day country dances; the May Day Show, which really was a pagan celebration on the return of Spring; Garland Day, at Abbotsbury, in Dorset, where on the annual festival the fishing boats were decorated with garlands, which were afterwards thrown into the sea—a frankly pagan ceremony coming from the Mediterranean and really meaning the propitiation of Neptune, God of the sea; the Midsummer Fire in the hills of Northumberland, which had in the beginning been nothing but sun worship pure and simple; a custom in a Cornish village probably introduced from Greece, which consisted in the inhabitants dancing through all the houses in the village; and, finally, the Welsh Eisteddfod, which was nothing more nor less than a continuation of the ancient Druidical ceremonies.

Exhibition.

ISLE OF THANET PHOTOGRAPHIC SOCIETY.

THE following is the list of awards made by the judges, the Rev. F. C. Lambert, M.A., and Mr. W. H. Rogers, in this exhibition, held last week:—

For the Best Pictorial Print.—Silver Plaque: No. 172, P. F. Weeks (member).

OPEN CLASSES.

Class A.—Landscape and Seascape: Silver plaque, No. 15, E. J. Jarvis; bronze plaque, No. 31, P. F. Weeks (member); honourable mention, No. 9, F. C. Snell.

Class B.—Portraiture, Figure and Animal Studies: Silver Plaque, No. 58, Mrs. H. Morgan (member); bronze plaque, No. 57, J. W. Johnson; honourable mention, No. 50, G. M. Meyer.

Class C.—Architecture: Silver plaque, withheld; bronze plaque, No. 102, L. G. Hodgson (member); honourable mention, No. 105, W. Lombardi.

Class D.—Miscellaneous, Still Life, etc.: Silver plaque, No. 119, E. Seymour; bronze plaque, No. 114, F. C. Cobb; bronze plaque, No. 137, G. W. Simmers (member).

Class E.—Lantern Slides: Silver plaque, No. 60, "The Brew House, Lympne Castle," A. Vigar (member); bronze plaque, No. 34, "Cheedale," P. Solly (member); honourable mention, No. 5, "The Lavatorium," Rev. E. T. Clark.

MEMBERS' CLASSES.

Class F.—Pictorial Prints: Silver plaque, No. 172, P. F. Weeks; bronze plaque, No. 153, Mrs. H. Morgan; bronze plaque, No. 182, L. G. Hodgson; honourable mention, No. 194, J. Savage.

Class G.—Lantern Slides: Silver plaque, No. 96, "A Strong Breeze," P. F. Weeks; bronze plaque, No. 87, "Upper Surface, Sand Str," A. Vigar; bronze plaque, withheld.

CLASSES FOR MEMBERS WHO HAVE NOT PREVIOUSLY TAKEN AN AWARD.

Class H.—Pictorial Prints: Bronze plaque, No. 206, P. Solly; honourable mention, No. 214, W. B. Jones.

Class J.—Lantern Slides: Bronze plaque, No. 126, W. B. Jones.

FORTHCOMING EXHIBITIONS.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9; 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayre View, Muirkirk.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 12-14, 1905.—Boston Camera Club. Hon. Secretary, H. M. Hames, 65, West Street, Boston.

January 14-23, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Mitchell, 180, Browning Road, Manor Road, E.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 16-18, 1905.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 25-March 4, 1905.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11, 1905.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14, 1905.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

MESSRS. JEPSON AND CO., of Hanover Street, Leeds, send us a dainty little trade price-list for enlarging and printing in all processes, which they will be pleased to send to anyone on receipt of trade card. Their work has been favourably known to us for some time.

ROYALTY AND PHOTOGRAPHY.—It is tolerably well known the great interest that is taken in photography by our Royal Family. It seems also that the King and Queen of Portugal are great patrons of it, for we read in the "Standard" that after the midday luncheon of the shooting party, at the Duc d'Orleans' Evesham seat, photography occupied the party for some time afterwards, and that the King gave great gratification to the beaters by commanding that a picture should be taken of them in a group.

TECHNICAL EDUCATION.—According to a return which was issued one day last week, there was expended on technical education in England and Wales during the year 1902-3, the sum of £1,191,998 3s. This amount is exclusive of the sums allocated to intermediate and technical education under the Welsh Intermediate Education Act, 1889. The amount raised by loan on the security of the local rate under the Technical Instruction Acts was £149,665 1s. 6d. The amount of loans—so raised—outstanding was £1,159,941 11s. 7d., and the balance in hand of moneys received and allocated to technical instruction was £598,989 7s. 3d.

New Books.

"Who's Who." "Who's Who Year Book." Published by Adam and Charles Black, Soho Square, W.

These familiar scarlet-coated annuals have again made their appearance, and, judging from the thickness of "Who's Who," there is an increasing number of people considered to be worthy of the honour of inclusion in this archive of haut ton. The Year Book we have found very useful many a time for reference, and there is much to be found in it that one would not find in others of somewhat similar construction.

"The Adventures of Cock Robin and His Mate." By R. Kearton, F.Z.S. 120 illustrations. 240 pp. Price 6s. London: Cassell and Co., Ltd.

The latest Kearton volume should be popular with the little folk, for it deals with "Dicky-bird Land" in a manner at once engaging, simple, and lucid. An old cock robin is the narrator, and he has many interesting experiences to tell his chicks. These include his "adventures in and around a garden during the winter; his courtship and nest building in queer quarters, his observations upon other birds, and their interesting homes and habits; the wonderful ways of all kinds of chicks; a trip to the seaside, with stories of seabird life and character; the amusing mistakes he has seen chicks, fox cubs, and kittens make; what young Robins see and inquire about when they leave the nest; strange adventures with stoats, squirrels, jays, cats, and dogs." The illustrations show the Keartons' wonted skill in this branch of photographic work, although they perhaps are not so sensational as those that appear in some previous books of the series. Presumably a great many of the negatives were taken by telephotographic agency. All, at any rate, show most painstaking effort, and the book being, besides, one filled from cover to cover with natural history lore very clearly set forth, is one to be heartily commended to the purchaser of seasonable presents.

MESSRS. CADETT AND NEALL, LTD., of Ashted, the well known plate manufacturers, have sent us a sample of their plate boxes, which will for the future bear a label at one end so that they may be used for storing negatives, and the register of the numbers written on these labels, so that mere reference to an index will at once enable the desired negative to be found. The idea is ingenious and practical.

FROM Andree, of the Hopetoun Studio, Colombo, Ceylon, we have received a large parcel of pictorial postcards, which are not only interesting as giving a good insight into the people's customs and places of Ceylon, but also for their artistic composition and excellence as collotype prints. They are fully equal to any that we have seen done in England.

O. SICHEL AND CO., of 52, Bunhill Row, E.C., have just issued a new list of chemicals and other sundries, which merit the attention of our readers. The majority of them are put up in powder form, and will therefore be found extremely handy for touring. Two special lines we notice are the "Vivid" flashlight cartridges, which are put up in 20, 40, and 60 grains, all ready with a fuse and also founts of thin metallic letters, which are attached to a negative by an adhesive, and give very sharp and white titles. These we shall hope to notice later on after practical trial.

It is with regret that we have to record the death on Sunday morning last of Mr. John Blundell, Senior, in his seventy-eighth year. Mr. Blundell's connection with photography has been a long and honourable one, and many of our readers must have known him well. He had been ailing for about two years, and practically retired from business three years ago. He was a prominent freemason, and one of the old school, making this a great hobby, and, speaking from personal recollections of him in this connection, he was characterised by a geniality and kindness of heart to his younger brethren that much endeared him to them. We extend our sympathy and that of our readers to his family.

New Materials.

"Zambex" Cameras. Sold by R. and J. Beck, Ltd., 68, Cornhill, London, E.C.

Under this name the makers have introduced a new series of cameras, fitted with an extremely ingenious system of changing flat films and plates. The cameras are of the folding, box, and twin lens patterns, and may be obtained either fitted with a single lens, a symmetrical, planat, or Unofocal, and also with Bausch and Lomb or Cornex lenses. The folding cameras are fitted with the well-known and useful Cornex finder, and the box form, which has a fixed focus of ft., can be used with magnifiers. The camera sent to us for examination is the No. 3, fitted with a Unofocal of 4.75 focus, a Bausch and Lomb shutter, a Cornex index, and view finder, which can be used both for vertical and horizontal views. The front of the camera pulls out and automatically locks on the tailboard at infinity, and can be also lifted and set to any distance by the scale. It is further fitted with a rising front, two small but sensitive levels for vertical and horizontal use, and tailboard is mahogany and metal bound, and is provided with bushes for tripod screws. The whole of the metal parts are nickel-plated, and the instrument is well made, and works easily and smoothly, and measures $5\frac{1}{2}$ by $4\frac{1}{4}$ by $2\frac{1}{2}$ ins. The great novelty is the "Zambex" film and plate changer, which is the same in all the cameras, and we cannot do better than give the maker's description of it, which is as follows:—

The "Zambex" skeleton is a folded strip of paper with a film attached at each fold; in each of the 12 folds a film B is held in a flap at the top and two corner slots at the bottom, and an opaque card A is attached to the front. The "Zambex" skeleton loaded with films is contained in a double length opaque envelope (Fig. 1).

Fig. 1.—Zambex Skeleton in its Envelope.

The films are in the lower half of this envelope when unexposed, and are pulled into the upper half as they are used. The lower half of the envelope has an opening the size of the film through which the exposure is made, and around this opening is a stiff projecting edge of card (A) by which the "Zambex" Skeleton in its envelope is slid into a frame of the "Zambex" camera.

To expose the first film, the front tag is pulled up the slot in the envelope to the position (K) in Fig. 2. This removes the dummy A

Fig. 2.—Zambex Camera, Showing First Tag Pulled Up.

from the lower to the upper half of the envelope, leaving the first film uncovered ready for exposure. In turn, as each film is exposed, it is transferred from the lower half to the upper half of the envelope,

and when they have all been exposed they are pushed back to their original position, and the envelope can be removed from the camera and another set inserted.

"Zambex" skeletons may be removed from the camera for focussing, after each exposure, if required. Those films which have been exposed are simply pushed back to their original position, and the skeleton in its envelope removed from the camera.

The slot in the back of the "Zambex" envelope, along which the tags are pulled for transferring a film from the lower to the upper half, is so situated that although daylight can get to the back of the skeleton, the films or plates themselves are absolutely protected from light, and the changing can be done in the strongest sunlight without any fear of fogging.

These "Zambex" skeletons carry 12 cut films of any make. We have used this camera and changing system during the past week, and have found that all went as merry as a marriage bell, there was no hitch, and on development of the films we could find no scratches, nor fog, and it strikes us as being an efficient and satisfactory device for daylight loading of stiff flat films.

Griffin's Gas Bracket Printer. Sold by John J. Griffin and Sons, Ltd., Sardinia Street, London, W.C.

This ingenious little device is particularly intended for printing bromide or other developing papers by gaslight, and consists of a metal easel with spring clip, which will take any ordinary $\frac{1}{4}$, 5 by 4, or $\frac{1}{2}$ -plate printing frame, and which can be screwed to any existing gas bracket, and then raised or lowered till it is central with the light. It will be found extremely convenient, and will certainly ensure one constant factor—namely, a fixed distance, which is so

important when many prints have to be made from one negative. It will be found advantageous, too, when it is required to give the top or bottom of the negative more exposure, as the support may be raised or lowered during exposure, and, as sometimes happens, one side of a negative is denser than the other, it can be swung round during the whole or part of the exposure, so as to effect this purpose. It is an ingenious and useful adjunct to the dark room.

Auto-Pastel. Sold by the Autotype Company, 74, New Oxford Street, London, W.C.

Under this name the Autotype Company have introduced a process of pigment printing without transfer, somewhat analogous to gum bichromate, but differing from it, in that the pigmented coating becomes absolutely insoluble in hot or cold water, and development has to be effected by abrasion, which is most easily obtained by using a broad camel-hair brush. It is obvious from this that this gives enormous latitude for local and general treatment. The actual working of the process is extremely simple. To sensitise the paper it should be immersed for one minute in a 5 per cent. solution of bichromate of potash and dried in a dark warm room. The drying should take about half an hour. Printing from a fairly strong, well-exposed negative, the time required is about the same as for ordinary carbon printing. Full exposures may be given, as there is great latitude in development. After exposure remove the paper from the printing frame, and allow to soak for a few minutes in cold water. Several sheets may be placed in the cold water at the same time. Next take a tin dish containing water of a temperature from 120 to 150 degrees Fahrenheit (40 to 50 degrees Reaumur). Float the exposed paper face downwards for two or three minutes, keeping the dish moving at the time. Now take the sheet and turn it face upwards, and commence the development by gently brushing in all directions with a three or four inch

camel hair brush, commencing at one edge and working towards the centre. As the image begins to appear the development may be either local or general, according to the wishes of the operator. On completion of the development the prints are washed in cold water, and are then finished. If desired, they may be fixed by about ten minutes immersion in a 2½ per cent. solution of alum, but this is not really necessary. We have not yet had an opportunity of trying the process, but the specimen prints submitted to us are exceptionally pleasing, they have an absolutely dead matt. surface, and the grain of the pigments used is so fine that there is no distinction of detail and an absence of "blobbiness" which is too often the characteristic of home-made gum prints. The "Auto-Pastel" papers can, of course, be obtained in various colours.

The New "Agfa" Flashlight. Sold by Charles Zimmermann and Co., St. Mary-at-Hill, London, E.C.

One of the troubles of keeping a flashlight mixture is the possibility of the salts that are mixed with the magnesium becoming damp, and, further, the danger of mixing these. This new flashlight gets over the difficulties by keeping the magnesium separate from the salts till they are wanted, and then the salts, which are stored in a corked measure that practically forms a stopper to the bottle, are shaken up with the magnesium and the empty measure used to portion out the requisite quantity of flashlight mixture. Accompanying the bottle is a supply of touch paper, on one end of which the powder is heaped, and as this paper burns but slowly there is no difficulty in removing the hand from the proximity of danger, even although a match be used. From a practical trial of this we have found that the duration of the flash is very short, there is very little smoke, and a very brilliant light is given.

Patent News.

The following applications for patents were made between November 14 and 26, 1904:—

Apparatus and Film.—No. 24,677. "Improvements in Photographic Apparatus and Film." Paul Theodore Hahn.

Films.—No. 24,774. "Improvements in films for photography." Maurice Bry.

Developing Apparatus.—No. 24,910. "Improvements in apparatus for introducing developing, washing, fixing photographic plates, films, or sensitised surfaces without the use of a dark-room." Hays Tirmann and Hugo Tirmann.

Dark Slides.—No. 25,136. "Improvements in and relating to dark slides for photographic use." Howard Hearne Crosbie.

Printer and Vignetter.—No. 25,177. "Improved general printer and vignetter for photographic papers, films, and the like." George Wilson Morgan.

Shutter Camera.—No. 25,379. "Improvement in folding pocket and focal plane shutter camera." John Stratton Wright.

Shutters.—No. 25,383. "Improvements in photographic shutters." John Stratton Wright.

Camera.—No. 25,496. "Improvements in hand photographic cameras." Houghtons, Limited, and W. Dockree.

Sensitised Plates.—No. 25,718. "Improvements relating to sensitised plates for a process of colour photography." A. Lumière.

Colour Photography.—No. 25,752. "Improvements in colour photography." Arthur Henry Gittings.

Printing Frames.—No. 25,772. "Improvements in photographic printing frames." Alfred Schoeller.

The second number of "Herman's Occasional" is just to hand, and will be found interesting to professional photographers.

In consequence of the rapid extension of their Paisley branch Rae Bros. have been compelled to remove to larger and more central premises at 100, High Street, Paisley.

CROYDON CAMERA CLUB.

THE platinum toning of bromide prints was dealt with by Mr. H. Allen last week, who advocated a method of toning with an acidified solution of platinum salt and mercury, recently brought forward by Mr. C. W. Somerville. After fixation and thorough washing, prints are immersed in the following:—

A.	
Mercuric chloride	1 grain.
Citric acid	9 grains.
Water	1 oz.
B.	
Chloroplatinite of Potassium	2 grains.
Water	1 oz.

Equal quantities of A and B being taken, a few drops of a ten per cent. solution of bromide of potash rendered the whites clear, slightly altered the resulting tone, and hastened the action. Mr. Allen then proceeded to tone several prints, and a very pleasant sepia colour, inclining to warm brown, was obtained, together, nearly all cases, with a slight intensification of the image.

Should a still further intensification be required, then the print should be briefly washed, re-developed to the black stage with a negative staining developer, and again toned. The method was also applicable to lantern slides and transparencies. It had been claimed that owing to the addition of metallic platinum the image would be rendered more stable.

A somewhat lively discussion followed. Mr. W. H. Smith said that as bromide prints were claimed to be permanent, why add "more permanency"? He was, in addition, somewhat at a loss to see a novelty in the process, considering a very similar solution had been on the market for twenty years. He also pointed out that if

wished to keep the platinum salt in solution for a considerable period without deterioration, then a strength of 40 to 60 grains per ounce should be adopted, and the bottle kept away from strong light.

Mr. W. H. Rogers regarded the tones obtained as in no wise superior to those resulting from the hot hypo-alum bath; there was, in addition, more staining of the whites. Mr. Sellors thought the action of mercury hardly tended in the direction of permanency. The mere fact that prints had kept a certain number of years without deterioration was in itself no criterion. He had at home a print made with uranium over twelve years ago which still maintained its pristine beauty, no change being observable. This hardly coincided with general opinions regarding uranium.

The President, Mr. S. H. Wratten, thanked Mr. Allen for affording the most instructive and interesting evening, without expressing any opinion as to the permanency of bromide prints in general, but he might safely say that if the foundation of the image was of a fugitive nature, it did not matter very much what was put on top of it. He could not help regarding such a procedure as in the nature of veneering.

Dews and Notes.

POUGHAMPTON'S Monthly for November is to hand, and contains some valuable notes on novelties, etc.

Mr. WM. TYLAR, of Aston, Birmingham, has placed some new specially pliable cloth lantern slide binding strips on the market, which seem very satisfactory.

Mr. ARCHIBALD GOLDIE, F.R.P.S., a well-known Swansea photographer, who had won distinction for artistic work, on Thursday succumbed to an attack of phthisis.

The late Mr. Alex. Tate, C.E., was one of the original members and founders of the Ulster Amateur Photographic Society of Belfast, of which we omitted to note in the ALMANAC.

The Interstate Photographic Art Exhibition will be held under the auspices of the Amateur Photographic Association of Victoria in January, 1905, and numerous medals and other awards are offered.

The annual prize distribution and students' conversazione of the Hampton Institute is to be held to-night, the 9th inst., and the Hon. Lord Reay will distribute the prizes. The conversazione with members and students will be continued on the 10th.

Messrs. A. E. STALEY AND CO., of Thavies' Inn, Holborn Circus, request us to notify that they will be pleased to appoint agents for "Geka" specialities in the various British colonies, of which they are in the control from the above address.

Mr. OWEN BROOKS, photographer, Dewsbury Road, Leeds, has met with a nasty accident whilst motor cycling. He was riding down Clifton Hill when he collided with a milk cart, and was badly thrown. A broken collar bone is, happily, the most serious of his injuries.

The Fifth Annual Exhibition of the Weybridge Arts and Crafts Society was held last week, and Mr. Henry Stevens lent some of his well-known flower studies and other pictures, and Messrs. Bates, of Weybridge, were represented by a fine exhibit of portraits and miniatures on ivory.

OPTICAL Convention, 1905.—The Optical Convention will be held in London at a date towards the end of May, 1905. The president is Mr. R. T. Glazebrook, Director of the National Physical Laboratory. The list of vice-presidents includes Sir William Abney, Lord Blythburgh, Sir W. H. M. Christie, Astronomer Royal, Earl of Crawford, Lord Kelvin, Lord Rayleigh, and the Earl of Rosse. The treasurer is Mr. E. B. Knobel, and the honorary secretary Mr. F. J. Selby. The main object of the Convention is to bring into close sympathy the co-operation men interested in optical matters, from all sides of the question, theoretical, practical, and commercial. This it is proposed to do by holding a series of meetings for papers and discussions on optical questions; and a "Papers" Sub-committee has been appointed with Professor S. P. Thompson as chairman, and Mr. S. D. Palmer as secretary. It has also been decided to organise an exhibi-

tion, of a scientific character, of instruments manufactured in this country, with a view to showing the great progress recently made and of stimulating further efforts. Instrument makers and manufacturers are invited to assist the committee by sending for the purpose of the exhibition typical instruments and apparatus of their manufacture. It is not proposed to ask exhibitors to pay for space, but a nominal sum, to defray out of pocket expenses, would be charged to each firm whose goods are shown. This charge would not exceed one guinea for each class in which goods are exhibited. An illustrated catalogue will be prepared, which will describe the special character and advantage of any particular instrument. It is hoped that the catalogue may be especially serviceable to manufacturers in making their instruments known in colonial markets. An Exhibition and Catalogue Sub-committee, with Dr. Mullineux Walmsley as chairman, and Mr. F. J. Selby, as secretary, is already at work. A provisional list of classes which they have drawn up for the exhibition and catalogue is appended. Firms desirous to have their manufactures included in the catalogue, or to send apparatus for exhibition, are requested to communicate without delay to the secretary, and to forward as early as possible descriptions and particulars of their instruments. The following is the suggested classification of instruments:—(1) Materials and tools; (2) simple optical elements and testing apparatus; (3) astronomical instruments; (4) nautical instruments; (5) surveying instruments; (6) meteorological instruments; (7) spectacles and eyeglasses; (8) telescopes and binoculars; (9) microscopes and accessories, and apparatus for photo-micrography; (10) photographic apparatus; (11) projection apparatus; (12) apparatus for optical measurement—spectroscopes—refractometers—polarisation and interference apparatus—apparatus for measurement with optical aids; (13) photometric apparatus; (14) heliographs—range finders; (15) stereoscopes; (16) ophthalmic instruments and appliances; (17) apparatus for educational purposes; (18) mathematical and drawing instruments—calculating apparatus; (19) shop fittings and miscellaneous; (20) historical collection; (21) literature.

MESSRS. SPEAIGHT'S New Premises.—Last week we accepted the invitation of the managing directors of Speaight, Limited, the well-known photographers, to view their new and palatial premises erected by them at 157, New Bond Street, London, W., their old premises in Regent Street having proved too small for their ever increasing business. Access is gained to the galleries from New Bond Street through the magnificent entrance gates and porch, which is paved in Sicilian and Bleu Belge marbles, and panelled in oak with cross vaulted ceiling. Here are show cases containing examples of the company's work. The double doors of the lobby open on to the entrance corridor, the length of which is pleasantly broken by an alcove, the walls throughout having a dado of oak. The entrance hall, with its beautifully designed oak work, and its several balconies over, resembles in some ways the interior of an ancient country mansion. The staircase, which is one of the finest in London, is constructed in solid oak throughout, the details of the balustrading having been taken from some of Wren's famous work at Hampton Court. The floor of the entrance hall, like those of the galleries, are in polished teak. The galleries have balconies round them, supported by grouped Ionic columns in oak, having beautifully carved capitals. The Minstrel Gallery, from which clients waiting for their sittings have the opportunity of listening to excellent music, is situated over the managing director's offices, which are panelled in oak. The Lounge, where tea is served during the afternoon to clients, is on the half landing, and is a beautifully designed room, with a vaulted ceiling, supported by Doric columns. The mantelpiece is especially worthy of note, with its moulded Sienna marble slips of great beauty, the interior of the fireplace being built with very valuable Persian tiles of quaint designs. Outside the Lounge the oak balustrade of gallery is carried up as a screen, and contains some excellent carving. The various dressing rooms are approached from the Lounge, the one reserved for Royal and other distinguished clients being particularly handsome, its fireplace contains an interesting selection of Dutch tiles illustrating children at their various games. Great care has been paid to the heating of all these rooms. In the construction of the studio, which is twice the size of the former one at Regent Street, great care has been taken in order to obtain the maximum amount of light, which is so essential for the successful photographing of children. The ventilation and warming of the studio have also received special attention. Throughout the year the temperature is the same; in the winter the fresh air

passes over heated pipes, and in the summer through specially ventilated air chambers, over blocks of ice. The electric fans in the roof change the air of the studio every few seconds. In addition, during the summer, jets of water constantly play on the studio roof to assist in keeping it cool. The installation of the electric light in the studio is ingeniously arranged, enabling portraits to be taken with the same success during the dark days of the winter as in summer. Close to the photographic studio is the miniature studio, where, under the most favourable conditions of light, this important branch of the work is conducted. On the same floor are situated the cloak rooms, retouching studio (where we saw six lady retouchers hard at work), mounting, framing, and dispatch departments. On the third floor are printing department, kitchen, dressing room, and black and white studio; and above these the negative department, developing and toning room, dark room, and stores. Messrs. Speaight, who now possess one of the finest photographic studios in the whole world, are to be heartily congratulated on their enterprise and upon the excellent work that hangs upon their walls. We wish them the continued success which they undoubtedly deserve.

Commercial & Legal Intelligence

At the Middlesbrough Bankruptcy Court, on Friday last, before Mr. H. S. Crosby, Registrar, R. C. Clifford, photographer, came up for further examination. In reply to Mr. W. G. Simpson, Deputy-Official Receiver, bankrupt said he did not give up to the Official Receiver a life insurance policy because he thought he was out of benefit. Mr. Simpson: You had no right to keep a single paper. The Registrar informed the bankrupt that he must hand it over. The Bankrupt: All right. Mr. Simpson said the bankrupt's examination from beginning to end had been unsatisfactory in many ways. The examination was ultimately adjourned by the Registrar, sine die.

E. YOULDON, LTD.—Capital, £6,000 in £1 shares. Object, to acquire the business carried on at the East London Glass Bottle Works, Carter Street, Mile End, E., by F. Youldon, as E. Youldon, to adopt an agreement with the said vendor, and to carry on the business of glass bottle and glass manufacturers and merchants, druggists' sundriesmen, manufacturers of, and dealers in, optical, photographic, mathematical, and scientific apparatus, etc. No initial public issue. F. Youldon is the permanent managing director. Qualification, £50. Remuneration of managing director, £200 per annum and 20 per cent. of the surplus profits after dividend has been paid. Registered office: East London Glass Works, Carter Street, Mile End, E.

PHOTOGRAPHY AND ADVERTISING.—One of the most remarkable cases governing the relations between photography and advertisement ever tried before a court of law has just conferred additional fame upon a well-known Parisian actress, Mdlle. Carlier, who was sued by a leading furrier for £511. The lady did not dispute receipt of the furs, but pleaded that they were gifts to her in consideration of the furrier being permitted to publish photographs of her wearing his goods. One of these portraits was produced, and it contained a dedication by the furrier averring Mdlle. Carlier to be the "daintiest dame in Christendom." Perpending these things, the judge has non-suited the furrier, on the ground that £511 is not an unreasonable price to pay for having one's wares displayed to advantage by the "daintiest dame in Christendom."

RR A. H. Emons, 36, Basinghall Street, E.C.—The first meeting of the creditors interested under this failure took place at the London Bankruptcy Court, before Mr. Bowyer, Official Receiver. The statement of affairs filed by the debtor disclosed liabilities to unsecured creditors amounting to £271 13s., and assets, nil. It appeared that the receiving order was made on the petition of Mr. Emil Lowitz, of 73, Basinghall Street, E.C., a creditor. Debtor stated that he had never been in business on his own account, and was at present employed as a traveller for a photographic company at a salary of 30s. per week, out of which he paid his travelling expenses. He alleged his failure to have been brought about through an adverse judgment having been obtained in an action brought against him by the petitioning creditor. He was now trying to get that judgment set aside. As the debtor was unable to make any proposal of composition to his creditors, the estate was left in the hands of the Official Receiver for summary administration in the usual manner.

AN INDUSTRIAL AGREEMENT.

To the Editors.

Gentlemen,—Your quiet comment at the head of the extremely valuable extract from the journal down under which appears page 1,027 of your last issue has given me considerable cause to think.

I have been for twelve months an indentured apprentice to a respectable photographer, with whom personally I have not the slightest quarrel, but in face of this document I begin to ask myself whether the game is worth the candle. Here am I an apprentice on a minimum of £75, all paid, and for twelve months I have done nothing but develop plates; I have not yet officially made a print; I have not had a single lesson in retouching, in posing or lighting or enlarging. Am I to be five years before I learn all these?

Is this or a similar industrial agreement likely to be adopted in England? At present I feel dissatisfied, and the perusal of the paper in your last issue does not make me less so.—Yours faithfully,

INDENTURED APPRENTICE

To the Editors.

Gentlemen,—Like probably hundreds of others, I read with interest the report taken from the "Australian Photographic Journal" of "Studio Employers and the Photographic Employees' Association N.S.W.," which appeared in your last issue. It will very naturally occur to most of us assistants on reading the account that if employees of New South Wales can form a strong Association for their own protection and for the regulation of wages and hours of labour, why cannot a similar thing be done in the old country? The employers already have their Association, the "P.P.A.," and it is proposed to form a Benevolent Association. Now it seems to me that if an Association of employees were formed on the lines of the N.S.W. one a Benevolent Fund might be combined with it in the case of other trade societies, and if it could be made to oblige us for higher pay for our services we could the better afford to contribute to its funds; also that there would really be less need for such an institution than there is at present. The scale of pay, hours of labour, half holidays, etc., arranged by the N.S.W. Association will make the mouths of most of us assistants here water. Look through these regulations, I find that with my ten years' experience in every branch of photography my minimum wage would be £3 a week, with short hours, etc., while I have to work long ones just about half that sum; and if I were to throw up the berth I am sure scores who would take it up for even less than that. See the example set by our Australian confrères why should we follow it? Thanking you in anticipation for the insertion of my letter, I am, yours, etc.

A YORKSHIRE OPERATOR WITH TEN YEARS' EXPERIENCE

WHAT SHALL WE DO WITH OUR GIRLS?

To the Editors.

Gentlemen,—I am an amateur with a large family, and one that is growing in years if, thank heaven! not in numbers; the major being girls, might I ask some of your professional readers to kindly give us the true facts of the case as regards the employment of women, ladies if you like, in photography?

Is it really possible to learn photography from a few books, a portable studio, and twelve months' work and two or three months' studio?

Will a first-rate provincial photographer actually take a girl and teach her the business, and is it possible for a well-educated, sensible girl with this experience to make both ends meet on a capital outlay of £400?

I have two girls, now both at that age when they feel they want to be up and doing. Both have passed their matriculation, and is a B.A. of Newnham and a clever chemist; the other is an artist.

her finger tips, and having, alas! for my pocket, taken up amateur photography, they are wild to start as professionals, and have flung my face the extract from "The Englishwoman's Year-Book" which you reprint on page 1,032 of your last issue.

Personally, I gather that you printed this rather in sorrow than anger, and that the whole thing is piffle, but I should like to know. When a man has only one business and five growing girls, all eager to be emancipated from home and become independent, the prospects held out in the above extract are alluring to them, but not to him who has to find the money, and who signs himself—Yours faithfully, Folkestone, December 5.

AN ANXIOUS FATHER.

THE PROPOSED BENEVOLENT ASSOCIATION.

To the Editors.

Dear Sirs,—I noticed in your issue of 18th ult. the remarks relative to the difficulty of resuscitating the old Benevolent Fund or starting a new one, and the implication that photographers as a body will not help themselves. I am not sure that the inference is correct. I am not sufficiently acquainted with the *modus operandi* of the old Society to judge the cause of its apparent failure, but I am inclined to think that any Society worked purely on benevolent lines, and by that I mean depending wholly on voluntary subscriptions, and whose funds are administered by a central committee resident, say, in London, for the benefit of the infirm or unfortunate all over the country, is bound sooner or later to come to grief partly because those who start it give place to others on the committee, from one cause or another, and the fresh ones have not the same interest and do not put the same vigour into its working, and partly because, failing to touch but a fraction of those in need, others withdraw their support and become their own almoner, or give it to some local body who they feel more likely to be in touch with those of their own district than those at a great distance.

As one who had the privilege of starting a benefit society for a special class of men nearly forty years ago, and which has worked ever since, perhaps I may be allowed to say that to successfully and impartially work such is not the easiest thing in the world, and it is made more difficult by the fact that in every society of this kind, despite all precautions, some get into it who draw more than their fair share, and were it not that many others draw much less, and some nothing, the society would fail.

I do not think the inference correct, because photographers, as well as others, have the opportunity, if they will avail themselves of it, of paying a small sum weekly into some benefit society for which they receive a proportionate payment in time of sickness. I do not say that this will last at the rate it begins for any length of time, but it will be material help at such a time.

Unless in youth and health people are willing to contribute to some fund they can hardly expect to be kept by strangers when they grow old and infirm. Of course there are exceptions where a man gives his time and talent for the public weal, and whose health perhaps suddenly gives way or some misfortune overtakes him; such men have a claim on public support; they, even, do not always regret it, and if others did not interest themselves on their behalf but leave them to their own would, as they are usually the last to seek help for themselves.

I think rather, Sirs, the inference is that a great proportion of the body are helping themselves in some such way as I have indicated, they can as far as *ill-health is concerned*, but I do not see how any society can help for any length of time at all materially those who have either lost their business or are no longer able to attend to it. In the first instance I fear the work of investigating claims would tax too heavily any unpaid committee, and in the second you would naturally expect that a business man would get others into the working as he finds himself getting less able to do it. It is not a healthy thing for any body of men to expect charity, which, if I rightly understand, a benevolent society is intended to distribute.—Yours.

PROFESSIONAL.

A WARNING.

To the Editors.

Gentlemen,—We have received a letter from the publishers of the "Gardener's Magazine," a copy of which we enclose, and think

it only right to call attention to this and express our surprise at the impertinent tone of it, and hope that should any of your readers have received similar communication they will either treat it with the contempt that it deserves, or, better still, inform the writers that there is such a thing as a fee for reproduction. We enclose our card and remain,—Yours faithfully,

PROFESSIONAL.

[We have received several communications on the same subject. The following is the letter referred to:—

CCPY.

5.12.04.

Dear Sirs,—We are anxious to obtain immediately for use in the New Year number of this magazine one or two good picturesque photographs of garden or rural scenes containing figures. We want whole plate subjects or large. We want *pictures*, not merely ordinary views.

If you have any subjects which you think will suit our purpose we shall be much obliged if you can send them along to us *to-morrow morning*. We shall, of course, be pleased to mention the name of your firm in connection with any picture we use.—Yours faithfully,

(Signed) W. H. and L. COLLINGRIDGE.]

"THE INTERNATIONAL PHOTO EXCHANGE."

To the Editors.

Dear Sirs,—Thank you very much for inserting the notice in your paper of to-day's issue re "International Photographic Exchange." I regret to say that you omitted to mention that I would send particulars upon receipt of stamped, addressed envelope.—Yours truly,

ROBERT C. CARTER.

33, Enbrook Street, Queen's Park, Harrow Road, London, W.

December 2, 1904.

TRAILL TAYLOR MEMORIAL LECTURE.

To the Editors.

Dear Sirs,—I shall be much obliged if you will permit me to inform your readers that I have sent to the Honorary Secretaries of the London and suburban photographic societies a number of admission tickets to the Seventh Memorial Lecture, which will be given by Dr. Glazebrook, Director of the National Physical Laboratory, at the Rooms of the Royal Photographic Society, 66, Russell Square, on Thursday, December 15, at 8 p.m. Mr. Conrad Beck will take the chair.

The subject of the lecture will be, "Modern Physics in Relation to Photographic Lenses." It is Dr. Glazebrook's intention to deal with the testing of these instruments.

As it is possible there may be many who cannot avail themselves of the mode of distribution which has been adopted for the admission tickets, if they will send me a stamped, directed envelope I shall be happy to send them a supply through the post.—Faithfully yours,

P. EVERITT,

Hon. Secretary.

88, Evering Road, N.

December 3, 1904.

DETECTIVE CAMERAS.

To the Editors.

Gentlemen,—Can you, or any reader of the B.J., kindly inform me who was the first to apply the roller dark slide to the above?

Some years ago—in the eighties, if my memory serves me aright—I designed a hand camera fitted with a roller slide, a sketch of which was sent to the Kodak, or, as it was then designated, the Eastman Co. Some time afterwards the well-known Kodak was introduced.

I may add that my camera was the outcome of an article in one of the photographic annuals by Mr. Melton Prior, the war correspondent, wherein he emphasised the need in his avocation of an instrument that would enable him to make a number of consecutive exposures at a moment's notice, without the loss of time involved in inserting dark slides.

I do not in the least wish to detract from the credit due to the Kodak Company, who were the first to supply a perfect and reliable roller slide at a moderate price, and, in addition, a film, without which

such a contrivance was practically useless. But I would like to clear up a matter of photographic history on a point that is, to me, of particular interest.—Yours, etc.,
H. C. PARLOW.

16, Benin Street, Hither Green, S.E.

[We are, of course, quite unable to state who was the first to fit a roll holder to a hand camera. Roller slides date back to Relaudin, 1855; Melhuish, 1856; Burnett, 1857; Disderi and Audineau, 1862; and Warnerke, 1875. The article by Mr. Melton Prior appears in the B. J. ALMANAC for 1887, two years after the Eastman-Walker roll-holder had been medalled at the P.S.G.B., Inventions, and Royal Cornwall Polytechnic Society.—EDITORS.]

TO PREVENT YELLOW SPOTS IN C.C. PAPER.

To the Editors.

Gentlemen,—The following tip may be useful to some of my fellow readers of the B. J.:—It is absolutely necessary to have all dishes perfectly clean, and to have separate dishes for each kind of toning bath. Prints must be hand washed throughout. Blot off in clean paper and separate prints for drying on dry paper. Dry sufficiently for trimming, but not so that prints curl up. After trimming, immediately immerse in clean water till thoroughly pliable, and mount with good, fresh starch. Under no circumstances must print be superimposed for drying flat, and when mounted and bone dry should be put into wallets. The great secret is to keep the prints—after washing—separate from each other and well exposed to the air till bone dry.
C. E. M.

Grand Canary.

PUBLIC OBSERVATORIES.

To the Editors.

Gentlemen,—Referring to the remarks in the JOURNAL of November 19 about public observatories, you may be interested to know that we have had them in Glasgow for many years. They are placed in a number of the public parks round the outskirts of the city, and there is one right in the business centre, in George Square. They contain self-registering barometer and thermometer, wet and dry bulb thermometer, and some, but not all, have rain-gauge and anemometer; probably all the sites are not suitable for these last two instruments.

Every year the Superintendent of Parks issues a review of the weather, and a report on its influence on the vegetation in the parks. Also, when anything abnormal happens, such as great heat, or cold, or rainfall, the observations at each station are published in the local papers.—Yours truly,
November 28, 1904.

WM. GOODWIN.

HALATION.

To the Editors.

Dear Sirs,—On recommendation of a friend I tried Bluebell Metal Polish as a reducer of halation on negatives, and am pleased with the result, as it reduces it evenly and does not leave any impression that it has been rubbed down, as one often finds with spirits.

I applied it with cotton wool, rubbing over the halated parts firmly, and on a negative exposed inside a cabin where the port holes had a very strong halation round them.—Yours faithfully,

L. MADDOCK.

Mottingham, Kent.

A UNION WANTED.

To the Editors.

Gentlemen,—Referring to the letter which appeared in your valuable columns last week signed "Darkness," I quite agree with him. I think the time has come when something should be done to protect the trade. I am sure employers as well as employees would benefit by a union. I know several employers who have advertised for assistants, and when they have engaged one have found him to be an amateur, or in other ways unequal to his work, and knowing very little of the professional side of the business. This, of course, causes great inconvenience to the employers. It is all very well for amateurs to practise as a hobby, or even as a "side line," but it is ridiculous for them to take up photography as a profession before they know what it is.

If a union were formed, I might suggest that examinations could be held and certificates given to the successful candidates. This would be a security for employers, and would also give assistants a good idea of the amount of knowledge they had.

And also, as "Darkness" suggests, a union would be a great benefit in times of sickness or unemployment.

I think a little enthusiasm is all that is necessary.—Yours, etc.

WOULD-BE UNIONIST.

STUDIO LIGHTING.

To the Editors.

Gentlemen.—I have read with interest the articles that have appeared at different times in the columns of your valuable JOURNAL on studio lighting, and will esteem it a favour if you would allow me just a wee space in your paper, and will promise to be as concise as I possibly can, while omitting the customary "few don'ts."

The billiard ball and gas jet theory is all very well in its way but the effect on a smooth, round object is very different to that on the human face, which is composed of projections, depressions, and innumerable slight curves and elevations. But, I will hold that the light should come from only one source; and all doubts on the subject have been set at rest by the works of the world's greatest painters. It is the area of that source of light and the dividing off into blind that the photographer has to deal with.

In regarding the painter's studio there are two points I wish to touch upon.

First, that the rays of the sun never enter through the illuminating area, on account of their being located in countries north of 23½ deg. N. Lat., and the north side being glazed vertically.

It is just as important that the photographic studio should be free from the rays of the sun; and in order to do so the glazed portion must be inclined, or vertical, or both, according to the latitude of the country—to be precise, I would say, part of the country—in which the studio is erected.

If at 23½ deg., it must be vertical, and as it is no uncommon thing for buildings in countries of this latitude to have high-pitched roofs, the glazed portion, commencing 3 ft. from the floor, may safely be carried to 16 or 18, even 22 ft. in height, with glazed portion facing north in N. latitude and south in S. latitude.

In countries at 53 deg. N. latitude it may be vertical at 9 or 10 ft. from the floor, and then inclined 6 to 10 ft. at an angle of 60 deg. 30 m. on the north side.

On the Equator it must be inclined at an angle of 113 deg. 30 m. either north or south side.

All angles for intermediate latitudes north or south of the Equator may be found by the formula, $\alpha = 90 - (x - 23\frac{1}{2})$, in which the value of α varies for all values of x , or for all degrees north or south of the Equator.

Secondly, that the illuminating area of the painter's studio is about 60 sq. ft., which is not sufficient by a long way for a photographic studio, for the simple reason that it produces shadows with very sharp edges, which is rather an advantage to the painter because he can see at a glance where the light ends and the shadow begins, and can soften or strengthen where, and to what extent, he pleases.

If the light is increased to 144 sq. ft., the shadows are greatly softened, but the high lights are weakened at the same time, resulting in a flat image. If now the whole of the light is screened off with some grey material which transmits about one-third the quantity of light as ground glass, we have a shade thrown over the face of the sitter, but which still appears flat.

Now, if just a portion of about 4 ft. sq. be torn open the high lights and deep shadows immediately appear, and the sitter may be placed in any part of the studio and there will be roundness at all hours of the day, the position of the open space, whether high, low on the side, in advance of, or behind the sitter, being determined by the catch light in the eye.

For children and on dull days the clear open space will require to be enlarged.

The grey material may be divided into three or four pairs of blinds according to the length of studio, each 4 ft. in width, working on spring rollers, from top and bottom and meeting at the eaves.

I enclose a specimen which shows the amount of roundness it is possible to secure.

For fancy portraits there will be need of another set of blinds of some stouter fabric, but not opaque, which must run under them, and may be used either separately or in conjunction with the above. The interior of the studio to be painted or papered a medium grey.

Existing studios north of the Equator facing due north may with facility have their glazed portions altered to the proper angle. For glass houses facing all other points of the compass I can hold out no hope, except that they may more conveniently be rented as warehouses.

And in conclusion I may add that all black blinds, reflecting screens, ground glass, and scraps of tissue and brown paper be unceremoniously removed, tied together, labelled, and precipitately despatched to—ah, there's the difficulty—why, of course, Blackburn. What an appropriate name, too!

I am looking forward with fear and trembling to a R.S.V.P. of a correspondent, who will severely take me to task for metaphorically playing ping-pong with the photographic hemispheres. I must confess to a keen sense of guilt, and, considering my tender years, pray that after the sentence is passed it will be commuted to servitude for life in some photographic studio where people "is took" at 2s. 6d. for three cabinets.—Yours truly,
ANGLO-INDIAN.
Lahore, India, November 16, 1904.

PANIC at an Entertainment.—A serious panic occurred on Monday at the Salvation Army Barracks at Dudley. During a cinematograph entertainment, illustrative of the Life of Christ, the lantern exploded, and a mass of flame enveloped the place under the gallery. The panic which followed was indescribable. The audience was mainly composed of children, and a wild rush ensued. Happily the Army officials kept cool, and the place was cleared without anybody being seriously injured. The lantern was destroyed, and other damage done.

A THREE days' exhibition of members' work in connection with the North Middlesex Photographic Society was opened last week, at the Hanley Hall, Crouch Hill. There were considerably over 400 exhibits on view, and the exhibition is undoubtedly the best that has taken place since the society's formation, seventeen years ago. An interesting feature is the record section, which comprises a collection of photographs illustrative of parts of the borough and district before they became a suburb of London. Prizes have been awarded to the following for the best exhibits:—Messrs. Louis Dick, S. E. Wall, A. H. Lisett, and S. H. Bentley. Those successful with lantern transparencies are Messrs. E. Burton, Louis Dick, and T. A. Macdermott.

THE eleventh of the annual chemists' exhibitions, organised by the "British and Colonial Druggist," will be held at Covent Garden Opera House from March 13 to 17, 1905, and amongst the exhibits will be included optics and photography. Full information may be obtained from the "British and Colonial Druggist," 44, Bishopsgate Street Without, E.C. Amongst the rules and regulations we find the following:—Photography: Where the management of the exhibition considers that in order to get any class of work properly done it is necessary to give a monopoly to a firm or firms, the exhibitors will not be at liberty to employ or introduce any other houses into the exhibition to do that class of work. This applies to photography, and any work other than stand fitting of which the management may give notice.

BEFORE the Southampton Camera Club, on the 5th inst., Mr. H. C. Shelley, War Correspondent for the "Westminster Gazette" and "The King," gave an illustrated lecture on "The Kodak in Peace and War." The lecturer recounted his experience with the kodak in the South African War, declaring that the camera was almost indispensable, and was seldom left behind, whatever else had to be abandoned. The desirability of possessing a camera as a useful accessory in almost every sphere of life was admirably demonstrated, and its illimitable value for recording important events and retaining pleasing incidents of every day life, which would otherwise probably be forgotten, was thoroughly maintained to the entire satisfaction and appreciation of the audience, and was greatly enhanced by the aid of a large number of well selected lantern slides.

Answers to Correspondents.

*** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

*** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

*** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

*** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. W. Cook, Oaklea, Knott End, near Fleetwood. Photograph Showing Promenade and Rough Sea, Knott End.
E. Seath, 98, Church Street, Luton, Beds. Photograph of the Old Wheelplough Inn.
W. Williams, 24, High Street, Carnarvon. Photograph of Sunset on the Menai Straits from near Carnarvon.
J. Dawson, 13, Whitefriars Road, Hastings, Sussex. Photograph of Old Saint Leonards Boundary Archway.
E. O. Parkin, 58, Wilkinson Street, Sheffield. Two Photographs of A. Drake, J. A. Groves, W. Bennett, J. Donnelly; also Photographs of A. Brown, E. Needham, and W. Foulke, all of the Sheffield United Football Club.
E. O. Parkin, 58, Wilkinson Street, Sheffield. Two Photographs of W. H. Johnson, A. E. Priest, J. Lang; also Photograph of A. Annan, F. H. Milnes, and Group of the Sheffield United Football Club.
W. H. Hoare, 66, Oxford Street, Swansea. Photograph of Lych Gate, Sketty Church, near Swansea. Photograph of Scene in Brynmill Park, Swansea. Two Photographs of Sketty Church. Photograph of Scene in Victoria Park, Swansea, all Snow Scenes.

DRAWING REGISTERED:—

- H. E. Squibbs, 33, Fore Street, Bridgwater, Somerset. Drawing of Bridgwater Fifth of November Carnival, 1904.
E. B. P.—Use a convex lens of 16.3 in. or practically 16 in. for the 4in. focus and 10.3 for the 3½in. focus.

W. ARMSTRONG.—We are sorry to hear your experience, but it is obviously impossible for us to publish a list as you suggest. There is an old proverb, cheap and nasty.

BACKGROUND.—It is impossible, of course, for us to remember the exact article, but you can obtain somewhat similar articles from any of the wholesale houses that advertise in our pages.

IVY.—You must be a little more explicit. Was the agreement written or verbal? Certainly, in the face of the facts you state, you have a perfect right to claim full wages, but as to your other query, we cannot answer without knowing more facts.

OPINION WANTED.—"S. S." says:—"Kindly pass your candid opinion on enclosed retouching, and do you think I could improve myself by taking lessons?" In reply: The work is fairly good, but it is capable of improvement. We should advise you to take a few lessons—personally, instead of by correspondence.

ARTIFICIAL LIGHT.—G. MOORE asks: "Could you give me an idea how to show on a photograph that it received one second exposure? I can think of nothing that is positive enough, and it would be an immense help if we could take the interior of our room at night showing room, lamp, and sitter, and the exposure by some means or other." In reply: We should say that it would be a somewhat convincing proof of the shortness of the exposure if you were to take a series of pictures of young children, animals, etc. The sharpness of the pictures of such subjects would show that the exposure was rapid.

OBSTRUCTED LIGHT.—H. R. MEHEW asks: "Will you kindly advise me on the following:—On the opposite side of my studio is a large red brick and stone building, and when the sun is out it

reflects rather a yellow light; if I put a reflector, as per sketch, do you think it will improve matters, or what do you suggest?" In reply: If the reflector be placed as shown in the sketch it would certainly throw more light into the studio, but not in the direction it is most wanted. I would send it towards the roof instead of towards the sitter. If it be adopted, it should be placed lower down than is shown in the sketch. The best plan would be to whitewash the building if that be possible.

BLACK LINE PROCESS.—P. MAGEE says: "Thanks for your reply, but if you refer to my query again, I said it was not the Ferro Gallic process, it is a newer one. I enclose you a piece of one. As I stated previously, a negative on paper is made first, and the negative is all black like the border on the enclosed piece, and the lines are pure white. Printing ink enters into the process in some way. The method of printing is in a cylindrical lamp (electric). Can you say where these are to be obtained?" In reply: The cylindrical printing frames and lamps are supplied by the patentees, Messrs. B. J. Hall and Co., 39, Victoria Street, Westminster. They may also be able to supply you with the paper. Messrs. Marion and Co., we believe, supply a new paper for the purpose.

COPYRIGHT QUESTION.—"Gaslight" writes:—"About six weeks ago I sent my assistant to photograph a group of potato pickers. After seeing the proof, they ordered ten half-plate copies. When the copies were delivered the men had no money, and only one was sold for 1s. I have now found out that their employer has issued a book in which appears a reproduction of my photograph. The negative is now copyright, but was not at the time the block was made. The question is: Had the author of the book any right to use the print without my permission?" In reply: The author of the book had no right to reproduce the print, and as it is now copyright you can prevent any further sale of the book. This is a case which should certainly be placed in the hands of the Copyright Union.

SEPIA PAPER.—THISTLE writes as follows: "On page 803 of the 'Almanack' for 1902 appears an article 'Sepia Paper.' Now, it was just what I wanted, and described as simply made. Well, I tried it but failed. I am an old wet plate worker, so I am not careless. I tried it again, but again failed, so I gave it up. Recently I came across the article again, and thought I would give it a trial again, but with the same result as before. The chemicals were the best. I get the green colours all right, but it is opaque, and a dense white precipitate settles to the bottom of the bottle, and it won't print but a faint, dirty image. I seem to go wrong on adding the silver citrate solution. It is then the dense white precipitation takes place. In reply: We cannot say where you have gone wrong, which you should not have done if you had closely followed the instructions. Possibly you did not add sufficient ammonia. When you try again use more, and see the effect.

COPYRIGHT QUERIES.—"R. E. S." writes: "A man here, calling himself a photographer, purchases my 12 x 10 and other views, and without permission has them reproduced as postcards, for sale in the shops and bazaars. I shall be much obliged if you will reply to the following questions:—(1) Can I stop the sale without copyrighting the photographs? (2) If I copyright now can I stop sale of those he has already reproduced? (3) Can I obtain any redress or punish the man in any way?" In reply: (1) No; certainly not. (2) If you register the copyright now you can obtain an injunction to restrain further sales of the pictures. (3) No. You can obtain no redress whatever for anything that was done prior to registration. Our correspondent finds himself in the position of hundreds of others who neglect to register their copyrights in the first instance. Had he registered them he could have obtained a penalty for every print made, damages, forfeiture of all negatives, blocks, and prints in existence. Also an injunction restraining, etc. He has only himself to blame for his neglect.

OCCUPATION WANTED.—INQUIRER says: "I should be extremely obliged if you would give me your advice upon the following questions:—I am in the want of an occupation, and a friend,

interested in photography, suggests retouching as a means of earning a livelihood, but looking through the pages of the Journal I see, from the retouching advertisements that the rate of pay seems to be very low considering the amount of time. Three hours I am told—that must be spent on each negative. I may mention that I have attended an Art class for several years, and have taken first-class certificates for nearly all subjects taught there, including one for advanced light and shade drawing. Considering the training I have received should like to ask your opinion upon these two questions: (1) Do you think there is a reasonable chance of earning a living at retouching. And, if so, (2) Do you think it possible to gain a knowledge of the method of retouching through post-lessons?" In reply: (1) The photographic labour market is at the present time so much overstocked, especially with retouchers, that we should advise you to look in some other direction in which to employ your talents. It is not necessary, however, that three hours be spent over each negative. (2) Yes, but not so well as by personal instruction.

TERMS OF AGREEMENT.—"C. B." says:—"This week I shall be obliged to you if you will enlighten me on the following 'point': In an agreement it is stated that 'I am not to set up business without the written consent of the Principal, or his successors.' It is the last three words that I would like your advice upon—whether it is right to be there, or not. The agreement is between the writer and the Principal (I will call him Mr. Brown) and him only. The point I want to know is this: would it or no make the present agreement invalid if at any time hereafter the business should be disposed of, or assume a new name, the addition of another partner's name, or 'and Co.,' or say, his wife, or sister, or any of those carry it on, am I right in presuming that it would be absolutely necessary that his successors, whoever they may be, should have a fresh agreement in their name or name for their further protection? The other agreement could I possibly stand in the one man name." In reply: We adhere to our opinion that the agreement is far too drastic, and you should not sign. The particular three words to which you now direct our attention are bad in law, because they would be held in equity to be an undue restraint of trade. Certainly it would not be necessary for any successor or successors to have a fresh agreement, as they could hold you to this if you signed it, but if you set up contrary to the provisions of the agreement then Mr. Brown or his successors could bring an action against you, and you would have to defend and would probably cost you a heavy amount; but to prevent you from setting up, within a given distance in perpetuity, is bad in law.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Unbreakable Ware. It is reported that a firm of Liège in Belgium has produced a special kind of ware which closely resembles fine translucent china, and which it is almost impossible to break. The United States Consul for Belgium has stated that he saw pieces of the ware used to drive nails into wood, and others thrown about on a stone floor without their being damaged. The special property is said to be due to a hardening process and to the nature of the materials used. The manufacture of photographic dishes and measures in this material would be a great boon both to amateurs and professionals.

* * *

Infringed Copyrights. Photographic publishers have not of late years suffered by the piracy of their works to the same extent as they did at one time. The case seems to be quite different with publishers of music. Each month we read that, during the previous one, so many tens of thousands of pirated copies have been seized by the Musical Copyright Association. Last week a pirate was proceeded against in the King's Bench Division, and he was mulcted in damages and costs, and a perpetual injunction was granted restraining him from further piracy of the plaintiff's music. In pronouncing judgment, Mr. Justice Kennedy told the defendant that if he broke the injunction he would be liable to be sent to prison for contempt of court. Contempt of court is a very serious matter, as the one in contempt may be kept in prison for an indefinite time, at the will of the court.

A Business Hint. The picture postcard, although it took a long time to get acclimatised in this country, after it had been well established on the Con-

tinient, is now well with us, and has come to stay—or at least until something supersedes it. Almost every scene, and every point of view of it, has been utilised by local photographers for publication as postcards, and there seems to be little left to be done so far as points of view are concerned. The only thing that now appears possible is to retake many of the views under different aspects, say, for example, when they are snow or frost clad. In the metropolitan district, up to the present, there has been little opportunity for obtaining snow-clad scenes, for what snow we had quickly disappeared. It was not so, however, in some of the provinces. But did local photographers take full advantage of it while it lasted? The "high street" and other points of interest in country towns have been photographed from almost every direction, but few, we think, when they coated with freshly-fallen snow, which gives them quite a different aspect. These snow-clad scenes would, no doubt, command but little sale during the summer months, but the thing would be different during the winter ones, particularly about Christmas and New Year time. It is a little late, perhaps, in the season now to put such pictures on the market if the negatives are not already secured. Ours is a fickle climate, and we may get but little more snow this winter; but there is ample time for plenty of it yet, and perhaps be followed by hoar frosts towards spring time. What we suggest to photographers is that they lose no opportunity, when it occurs, of securing snow-clad scenes in their districts, or of their principal streets, and before the snow is disturbed by traffic, etc., if possible, and to keep the negatives till next year if too late for profitable publication this. Photographs can be taken at a minute's notice, but not so snow pictures in this country. The opportunity of obtaining them is not often, and it should not be lost when it occurs. The above hint may be useful to those professionals to whom it may not have occurred.

The International Copyright Convention—Another Accession.

One day last week a Parliamentary Paper (Treaty Series No. 11) was issued announcing Sweden's accession to the International Copyright Convention. In this Sweden has followed the example set by Norway some little time back. The Swedish accession takes effect from August 1 of this year. Now all pictures, including photographs, made copyright in Sweden become copyright in this country, and at the same time all photographs copyrighted here become copyright in Sweden. It is not known to all those who register the copyright in their photographs at Stationers' Hall that they become automatically copyright in every other country that is a party to the Berne Convention of 1886, and that it endures in them for the same length of time as it does here. All that is necessary under this convention is that the copyright law of any of the countries,

of course, parties to the convention, be complied with, and the works are then copyright in them all. In this country registration is necessary; in some it is not—in Germany, for example. There, merely publishing the work is sufficient to secure the copyright, and the work becomes copyright here without registration at Stationers' Hall. We have frequently been asked, through the correspondence column, if the reproductions of the paintings in the Continental galleries, and in our own, that are produced by German firms are copyright if they are not registered at Stationers' Hall. As it may be fairly assumed that all these pictures are first published in Germany, where registration is unnecessary, it may be taken for granted that they are all copyright in this country. Heavy damages have from time to time been recovered in this country for infringements of it, as some know to their cost. The United States are not a party to the International Convention, and, as a result, English and Continental works are largely pirated there, and there is no remedy.

* * *

The Metric System.

The Canadian Government, according to the *Standard's* correspondent, is about to introduce legislation to make the metric system of weights and measures the only legal standard. Some years' notice will be given before the change takes effect. At present both the English and metric systems are permissible (as in England), while the French standards obtain in Quebec. Sooner or later, there is very little doubt, the metric system will be the only legal standard in this country, but, according to present ideas, it will not be quite in the near future. It seems a pity that this system should not be universally adopted by photographers, seeing the great convenience it would be to them in many ways, more especially when dealing with foreign formulæ. These are usually written under the metric system, and often the components of them are given in percentage solutions. Now, the making of an ounce or two of a certain percentage solution with English weights and measures often proves puzzling to some, whereas if the metric system were in vogue the thing would be "plain sailing," even to the most ignorant with figures. Again, in converting grammes and cubic centimetres into English grains and ounces, when only small quantities are concerned, the formulæ often suffers. We have heard very many photographers speak favourably of the metric system, and say they wished it were adopted, yet they do not use it in their own practice. Why? Just recently we were asked where metric weights and measures were to be obtained, and we replied, at once, "Of any of the dealers," but we were told that we were under a misapprehension on this point, for they could not, as they did not stock them. On reference to the catalogue (of several hundred pages) of one of our largest London houses, although some half-dozen pages are devoted to weights, measures, and scales, metric weights and measures are not listed, nor is any reference whatever made to them. If metric weights and measures are not easily procurable, and at a moderate price, it is not promising that the system will be universally adopted in the near future by the general body of photographers.

* * *

Intensification It frequently happens that a print is **unlimited**, required from a negative in which the details are so faint that it seems almost a hopeless task to start on it. The following method which has been suggested by M. Popowsky before the Russian Photographic Society, whilst a lot of trouble, is probably the most satisfactory. On the negative is fastened at one corner a little right angle of cardboard, so as to ensure the accurate

register of the glass that is used to obtain the print. M. Popowsky used a collodio-chloride emulsion made according to the formula of Kleffel, thus:—

1. Water	6 parts.
Silver Nitrate	5 parts.
Alcohol 90 deg.....	100 parts.
2. Calcium Chloride	2 parts.
Alcohol 90 deg.....	100 parts.
3. Citric Acid	2 parts.
Alcohol 90 deg.....	100 parts.

No. 1 is added in small quantities and with constant shaking to 240 parts of a $1\frac{1}{2}$ per cent. collodion, and then Nos. 2 and 3 are added drop by drop with constant shaking, and the emulsion allowed to stand for an hour or two to ripen. A sheet of glass is coated with this emulsion, and when dry is placed in contact with the negative, and a faint image printed out and developed to full intensity with

Gallic Acid	5 parts.
Lead Acetate	3 parts.
Acetic Acid	7 parts.
Water	1,500 parts.

The print is then fixed, washed, and dried and coated with

Rubber Solution	30 parts.
Toluol	70 parts.

The rubber solution should be of 5 per cent. strength in benzole. When this is dry, another collodion coating is given and again it is printed out and again developed, fixed, and dried, and these operations repeated till an image of sufficient intensity is obtained, from which a duplicate negative can be made.

The Steadman System of Exposure.

The Photographers' Association of America, or, as it is familiarly known, the P.A. of A., appointed a committee to confer with Mr. Steadman upon his system of measuring light and speeding plates, and their report runs as follows:—"We believe that to express the intensity of light in simple numbers, and to think of it in units, as we now consider temperature and volume, would tend to great simplification in the practice of photography. Mr. Steadman's method of doing this seems thoroughly practical. Actinometers have for many years been in successful use, and the theory involved is known to be practical. The different meters, as now made, differ one from the other in the degree of work that the light is allowed to perform, such work being determined by a tint selected arbitrarily by the manufacturers, and to which the discolouring paper is designed to match in its discoloration in the light. For this reason no uniformity of measurement through the world can possibly exist. The use of special papers, as well as the necessity of buying a meter, also prohibits a world-wide standard. For the reason that Mr. Steadman's method is based on paper always at hand in all parts of the world, and that no expense is involved beyond the strips of paper used and a small pocket note book with a hole in the corner, in which to tint it, your committee take pleasure in recommending the following standards for the measurements of light intensity:—For the standard paper for the measurement of light intensity, we recommend *solio*, and all printing-out paper which, on measurement, shall be found to agree with it in sensitiveness. For the standard amount of work that the light shall do, we recommend that degree of discoloration which becomes first plainly distinguishable from the original colour of the untinted paper. Such tint to be made through a hole in any thin opaque material, as the corner of a note book, the cover being raised to observe the tint. For the scale of values

we recommend the following as practicable:—One-eighth, one-fourth, one-half, one, two, four, eight, sixteen, thirty-two seconds, one, two, four, etc., minutes. For greater accuracy, the interval half-way between any two of the scale may be used, as three, six, or twelve seconds. The shortest interval, one-eighth of a second, is the intensity of the light out of doors on a clear day with the sun from fifty to ninety degrees above the horizon, and no shorter, greater intensity therefore exists under ordinary natural circumstances. Therefore, as to Mr. Steadman's method of speeding plates, we recommend that the Association officially request each and all of the plate and film manufacturers of the United States to investigate the method, with a view to establishing a uniform system, should the method be found satisfactory." It will doubtless be remembered by our readers that there was considerable discussion on this system in our pages during July and August.

* * *

Colour Photo-raphy Again. At the Convention of the Photographers' Association of America, a Mr. C. W. South discoursed on this subject, and introduced his own particular process, which he calls the "Solgram." His description of it leaves much to be desired, but we give it for what it is worth. He says: "A process for producing photographic prints in colours from the excellent negatives now possible must be simple and easy to work, permanent in result, and a printing-out process requiring methods of working not far removed from the monochrome processes now so extensively used. Such a process, I believe, I shall have the pleasure of demonstrating to you now, and which I call the 'Solgram.' The three-colour theory, which is well known to most of you, is the basis of all colour processes, whether direct or indirect. This theory has been resisted and turned in every way to accomplish the desired end—a photographic print or photograph in natural colours. For years I have been convinced that the three colours—yellow, red, and blue—had some particular office in the world of art except tinting objects, and I invented the Solgram to prove my theory—namely, that red was the base and warmth of a picture, blue was the great drawing-master, giving detail, shadow, and form; and yellow gave to our work light and life. I reasoned with myself thus—if red is the base, it should be placed first upon our paper (or suitable substance)—and as its office was simply to give warmth, tone, or colour, it need not be sharp and wiry, therefore the old gum bichromate pigment process would suffice, with the advantages that the pigment could be chosen for permanency, and also that by reason of its colour the print upon which a service would be variable, fading away with actinometers, etc. After printing and washing, we would obtain a beautiful crimson picture. Now for the blue print, which gives detail, drawing, form, and shadow, the gum pigment process, I was convinced, would not suffice for several reasons. (1) Above all, if a blue gum pigment should be painted over our red image, it would obliterate it, making it impossible for anyone, save an expert, to obtain correct registration. (2) As the blue print is to be used for detail, form, etc., the gum pigment print would be very unsatisfactory; thus I was led to adopt a chemical compound which would give the required colour upon being exposed to light. This idea carried out, I at once accomplished the two main points in practical colour-photography. (3) The yellow, which gives light, sparkle, and life to a picture, could be printed last over the compound image, crimson and blue giving a finished print. This last print, which, like the first (crimson print) had nothing to do with the drawing, could be made by the gum pigment process, care being taken that the yellow should not be opaque. Thus I invented the

Solgram process. However, after all this work was completed, I worked to perfect and form a complete colour balance so essential to obtain pictures which would not appear false."

A PRINTING-OUT GUM PAPER.

Dr. Reiss recently suggested at a meeting of the Société Française de Photographie the use of an emulsion of gum arabic and silver nitrate for printing out, and whilst we cannot quite see the advantages that the process has over any other plain paper process, his notes may lead some to experiment in this direction.

Gum arabic has been suggested as an addition to a gelatino-bromide emulsion, and it is stated that it gives greater density and freedom from fog; but this is a debatable point; it at least has found no general application. M. J. Liddee has prepared sensitive cloth or fabric by immersion for fifteen minutes in a solution of

Gum arabic...	32 g.
Sodium chloride	8 g.
Water	1000 cc.

After drying, this was sensitised by immersion in a 10 per cent. solution of nitrate of silver.

Dr. Reiss's process is, however, he suggests, quite new, and he says that although the results obtainable are very fine, the process is capable of improvement, particularly as regards the keeping of the paper before printing.

Any well-sized paper may be used; in fact, it is absolutely essential that it should be well sized, otherwise the image is flat and wanting in vigour. The well-known Canson's drawing paper, or good English writing paper, were found satisfactory.

To make the emulsion, 100 grammes of powdered gum arabic are dissolved in 100 ccm. of water; of this solution 5 grammes should be placed in a small porcelain or glass mortar, and 3 ccm. of glacial acetic acid added. The gum is coagulated at once, but on rubbing up vigorously a perfectly homogeneous mass or emulsion can be obtained. To this, then, is added, by yellow light, a solution of 1 gramme of silver nitrate in 3 ccm. of water, and the mixture again worked up into an homogeneous emulsion.

To sensitise the paper, it should be fastened to a sheet of stout cardboard or a drawing-board, and the emulsion spread over it with a round, stiff, hog's hair brush, and the marks evened out with a flat hog's hair brush. Too soft a brush soaks up too much emulsion. It is important to ensure a regular coating, to coat quickly, and to keep the brushes very clean; after each time of using they must be repeatedly washed in hot water.

The quantity of emulsion required to coat a sheet 18 by 24 cm. is about 3 ccm. The coated paper should be suspended by a corner, and will completely dry in from ten to fifteen minutes in a well ventilated and cold room. It is of course unnecessary to add that the operations must be carried out by artificial light, or in a room illuminated by yellow light.

As soon as dry, the paper should be printed. The prepared side is shiny and possesses a faint yellow tinge; it can be kept from twenty-four to forty-eight hours before printing, but it then becomes rather deeper coloured, but this disappears in fixing. If the paper is kept longer the coloration deepens in ratio to the time it is kept.

Printing is effected in the usual way, and the sensitiveness of the paper varies with the nature of the paper and the time the paper has been kept. Canson's paper prints more rapidly than the English writing paper. The quality of the paper has not only an influence on the sensitiveness of the paper, but it also determines the tone of the print.

Whilst the one prints in a red bistre, the other prints to a brown. The sensitiveness of the argentic gum paper is practically the same as that of Lumière's citrate paper.

It is obvious that the variation in the colour of the print and its sensitiveness is greatly dependent upon the size that is used, and an animal sized paper such as English writing-paper may give a totally different result to a resin-sized paper, such as I fancy Canson's is.

Printing must be carried further than is required in the finished print, as there is a reduction of intensity in toning and fixing. Freshly prepared paper gives the best results with plucky negatives. Soft negatives, however, give equally satisfactory results. After printing the whites of the print should have a faint brownish orange tint.

After printing the print is immersed in ordinary water, and the whites become quite clear, washing should be continued for fifteen minutes in running water, and the print should then be immersed in a 2 per cent. solution of hypo for ten minutes, and it should then be washed for an hour and hung up to dry. When dry the print is a rich brown.

If the ordinary photographic tones are required, then the ordinary methods of toning must be adopted, such as gold or platinum, or gold followed by platinum. To obtain prints rivaling platinotypes in colour, Namias's bath should be used:—

Chloroplatinite of Potash	1 part.
Distilled Water	1,000 parts.
Pure Hydrochloric Acid.....	5 "
Oxalic Acid	10 "

After toning in this, the print must be washed in running water for fifteen minutes, and then fixed as suggested above.

To obtain pure black tones the print should be first treated with:—

Borax	10 parts.
Sodium Acetate	10 "
Chloride of Gold (1 per cent. sol.)	50 "
Water	1,000 "

Then well washed and toned in Namias's platinum bath given above.

Violet tones are obtained by printing very deeply and toning after a good preliminary wash in

Water	1,000 parts.
Hydrochloric Acid (pure).....	20 "
Chloride of Gold (1 per cent. sol.)	50 "

The print is much reduced in this bath.

A very fine blue tone is obtained by treating the fixed and well-washed print with

Water	1,000 parts.
Ammonium Sulphocyanide ...	50 "
Chloride of Gold (1 per cent. sol.)	50 "

Finally Dr. Reiss has tried to increase the sensitiveness of the paper by the addition of a little gallic acid, and added three drops of a 1 per cent. solution of gallic acid to the first-mentioned quantity of emulsion. The result was greater sensitiveness, but obviously concurrently less keeping power.

Whether the above process is likely to be of any value I cannot express an opinion, but there are one or two suggestions that present themselves to me which may be worth consideration from the point of view of the experimentalist. In all probability, indeed, it is half suggested by Dr. Reiss that the whites of his prints are obtained by the gum dissolving away when the print is washed, why, then,

should we not combine the principle of gum bichromate printing with a silver image?

It is an old idea to immerse gelatino-chloride paper in bichromate and then print, but this gives us far too heavy a coating of gelatine. It might be possible to use Dr. Reiss's gum emulsion, and print out and then soak in bichromate solution, and then develop with warm water for Howard Farmer has proved that a metallic silver image in the presence of bichromate will render gelatine insoluble, and what is applicable to gelatine is in all probability applicable to another colloid like gum arabic. By applying this principle we could obtain an image of finely divided silver, suspended in gum or other colloid and could give to the man who wants to control his results by brush-work another process, which would give him an almost invisible grain and yet complete control over the tonality of his prints, I think much would be done to reconcile the gum-splodger and the average worker. For to me, the extremely coarse grain and blobbiness of the majority of bi-gum prints is excessively irritating. It is in fact, impossible to reproduce structure by the aid of the ordinary bi-gum, because of the coarseness of grain.

Dr. Reiss has also used nothing but silver nitrate. There is no reason why a chloride should not be incorporated with his emulsion, and as regards the keeping properties of it, it is generally known that the addition of citric acid or other organic acid will preserve a printing out emulsion for some time. In fact, it is not necessary to have an acid emulsion, or one with an excess of silver nitrate to obtain excellent results. Dr. Reiss's process makes for experiment, and, whilst I have added a suggestion or two, there are plenty which naturally occur, one, at least, rises to the front at the moment of writing—Why not incorporate a bichromate with the sensitiser?

E. J. WALL.

PYROGALLIC ACID AND ITS USE.

THIS name is apparently as fixed in photographic parlance as that of hyposulphite of soda, though each is a misnomer. It is true that "pyro" and "hypo" are the more commonly employed terms; but they are contractions of the originally used descriptive titles. The term "pyrogallie acid" was devised to express the idea of the substance being gallic acid sublimed, as first observed by Scheele, but whose true composition was shown by Pelouze and Berzelius. Any one can make an interesting experiment in its manufacture by placing a little dry extract of galls in a gallipot, fashioning a cap of white paper, tying it to the rim of the pot, and exposing the pot, in a sand-bath or otherwise to a temperature of 80 deg. to 85 deg. The gallic acid in the extract is sublimed, and parts with the elements of carbonic anhydride, condensing on the paper cap in the familiar form of flocculent crystals. Accepting the definition of "acid" to be "a salt of hydrogen," it is obvious that pyrogallie acid is an incorrect designation and that the comparatively recent word pyrogallol should take its place.

In the early days of collodion negative making, pyrogallie acid was the stand-by of all photographers. When dry plates came to the front pyro was still the developer, though for a long time opinions halted between its merits and those of ferrous oxalate. The latter was made by the direct dissolution of ferrous oxalate by the aid of oxalate of potassium. If, at the outset, the simple method of mixing solutions of ferrous sulphate and of oxalate had been devised, possibly the preference might still be undecided, for on the Continent the ferrous oxalate developer was still universally popular, when in Britain there was virtually no competitor against pyro. Whatever the actual

use, pyro became then, and has since continued, in almost universal vogue up to the last few years, until the introduction of the series of modern developers, the theory of whose composition and structure, with corresponding developing properties, owes so much to the investigations of Messrs. Lumière and Seyewitz. We have made inquiries among a large number of professional photographers as to their practice in developing plates, and, while finding a sprinkling of hydroquinone users, the vast majority still adhere to pyro. Some have taken to metol for a time; but many of these have given it up and returned to pyro. The question naturally arises: "Why is this so?" There are many possible replies. Thus, there are now such a multiplicity of new developers that it is difficult to discover, even from the manufacturers' own statements, the exact shades of differences between one and the other, the result being such a feeling of perplexity that the old pyro, whose properties are, or are supposed to be, so well known, is adopted, notwithstanding its drawbacks of finger staining and quick degradation of power after once using, etc. Pyro-soda, and, even, pyro-ammonia, can be used a second, and, even, a third time (in rapid succession), but lose much of their strength, a third development taking, perhaps, thrice the time to bring up the image to full density that the first use calls for. Metol and its congeners may be used many times over, and kept after use from day to day without injury. Yet, even these developers are not identical in properties after using. Each time that a plate is placed in them the action alters, though it be only slightly. As against metol, on the other hand, there is the peculiar sensitiveness to its action upon the skin exhibited by some constitutions. With regard to pyro and its finger-staining proclivities, we should not regret so much if a less slovenly manner of working were universal. It is simply marvellous to see the good pictures produced by some men, if the uncleanly modes of doing their work is noticed. If, before immersing the fingers in the pyro solution, or handling plates covered with it, the fingers be first dipped into water, so as to saturate the skin, as it were, with an innocuous liquid, very little pyro enters the pores, and if when the plates have been handled the fingers be well rinsed again and wiped on a towel (always to be placed ready to hand), there would be very little talk about finger-staining compared with what we now hear.

But the great point in favour of pyro is the gradual manner in which the image appears, and the common impression still prevailing that the ultimate gradations can be altered by the addition of suitable chemicals at an early stage before full printing strength has been arrived at, a property not shown by the more recent developers, under which the whole of the image flashes out at once and the continuation of the development being merely the requirement of density for printing purposes. Further, pyro is so much cheaper, weight for weight, than any of the others, even allowing for their use a second time. Under such commercial stress as now exists, every penny has to be looked at to make a commercial success.

Some photographers complain that pyro solution does not keep well, especially when once the bottle containing it is opened and put into use. But this need not be. The once-despised sulphite of soda is now in almost universal employment, varied by the substitution of metabisulphite. But sulphite alone will not answer for the purpose; it must have an acid added to it. Citric acid is handy and frequently made use of; nitric acid is not advisable, and is, further, liable to the presence of nitrous acid, which will cause the solution to turn brown, the reaction, indeed, forming an excellent test. The formula for a stock pyro

solution that we ourselves work by is: Pyro, one ounce, dissolved in a pint of 20 per cent. sulphite of soda solution, to which is added (before putting in the pyro) half an ounce of 10 per cent. solution of sulphuric acid. This is perfectly colourless when made, and will remain so for a long time.

Finally, we may refer to a form of pyro put upon the market during the last few years—that of small transparent crystals, a pound of which occupies very little more space than an ounce of the old form of sublimed pyro in flocculent crystals. We have given it a thorough trial, and our opinion is that no one using a solution of the sublimed and of the crystalline form could distinguish the action of one from the other. There is no mess, no feathery crystals to blow about in the air and settle upon plates or prints—the crystals are rapidly weighed and they quickly dissolve. A further advantage is that the price of the crystalline is about 10 per cent. below that of the feathery form.

SILVER PRINTING IN WINTER.

THE dull weather, accompanied as it too often is by extreme damp, is a sore trial to the silver printer. Not only will it frequently happen that one P.O.P. print cannot be obtained from a negative in a day, but there is also great chance of silver stains. The varnishing of negatives during the prevalence of such weather as we have been having of late is an absolute essential; one may omit it in summer, but never in winter.

It is fortunate that we can, however, obtain only a faint image on gelatino-chloride paper and then develop it up to full strength, and this method is not only of great value in the saving of time, but the results are not to be distinguished when the operation is properly carried out from a fully printed-out picture.

There are two distinct methods that may be used, the one in which an acid developer is used, into which the print is placed without washing, and in which the process of physical development is taken advantage of, and the other in which an alkaline developer is used, and the soluble silver salts in the print are converted into insoluble bromide of silver by immersion of the print in a strong solution of an alkaline bromide.

When an acid developer is used it frequently happens that the colour of the print is satisfactory, and no toning at all is required, but as a rule it is much more satisfactory to use a gold bath.

One of the most satisfactory acid developers is that suggested by Valenta, which is as follows:—

1. Hydroquinone	1 oz.
Alcohol	10 oz.
2. Sodium sulphite	2 oz.
Citric acid	48 gr.
Water	10 oz.

For use, mix half an ounce of Nos. 1 and 2, and add half a pint of water. The prints should be immersed in this and kept on the move, till the desired depth is reached, which will as a rule take about fifteen minutes, and should then be immersed in a 5 per cent. solution of common salt to stop the developing action, and then thoroughly washed and toned.

Pyrocatechine may be used instead of the hydroquinone in the above formula, and it gives tones than tend more to violet, whilst if a very quick developer is desired, though there is no other advantage, pyrogallol may be used. For some years, on the Continent, there has been a one solution

developer obtainable commercially, the composition of which is practically as follows:—

Hydroquinone	50 gr.
Sodium acetate	50 gr.
Citric acid	50 gr.
Sodium sulphite	50 gr.
Water	20 oz.

and this acts very satisfactorily.

The second method, that by the use of an alkaline developer, is, however, preferable to the acid developer. It is certainly more certain in its action, and if due precautions be taken on one or two points the chances of failure are relatively small.

If a piece of gelatino-chloride paper be immersed in an alkaline developer, it turns instantly either green or black all over, or becomes covered with an iridescent film of reduced silver, and any image there might have been on it is lost in the general reduction of the silver. If, however, the paper, with its faintly impressed image, be immersed for five or ten minutes in a 5 per cent. solution of potassium bromide, the whole of the silver salts, the chloride as well as the free nitrate or organic salts of silver, are converted into bromide of silver, and in all probability the light affected silver salts are converted into lower compounds of silver bromide. On the immersion of such a print into an alkaline developer we have nothing more than ordinary development, though there is a possibility that when a developer containing a large proportion of bromide is used, of some of the silver salts being dissolved and instantly precipitated on the image.

One of the most important points is to avoid as far as possible the access of any strong actinic light to the paper whilst filling the frames or examining the prints. The faint and invisible action which then takes place, whilst quite impossible to detect when the print is fully printed out and treated in the ordinary way, becomes distinctly visible by the development process, and leads to a degradation of the whites which is undesirable.

It is advisable to well wash the prints after immersion in the bromide solution, otherwise irregularities in the developer may occur. Development must not be carried far; in fact, the print when sufficiently developed should be a very pale yellowish orange, and the detail in the highest lights should certainly be wanting. If artificial light be used, it is somewhat difficult to judge the progress or final stage of development, but this can be got over by a somewhat ingenious idea that we lately saw in use, and that was the use of a sheet of glass coated with gelatine and stained with methyl violet in front of the light, which makes the yellow image show up very strongly.

After development the print must be thoroughly washed. This is most important, for the slightest trace of developer in the paper or film at once reduces the gold of the toning bath, and a faint purple tint is seen over the whole of the print, both back and front.

Various formula have been given for the alkaline developer, but one of the simplest is that suggested by the Paget Prize Plate Company:—

1. Hydroquinone	1/2 oz.
Sodium sulphite	2 oz.
Water	110 oz.
2. Potassium bromide	15 oz.
Sodium carbonate	12 oz.
Water	112 oz.

For normal results mix 1/2 oz. No. 1, 1 oz. No. 2, and 1/2 oz. water; for greater contrast reduce No. 1, and for less contrast increase No. 1, and proportionately reduce or

increase the quantity of water, so that the total bulk of the solution is kept constant.

Either the separate or combined baths may be used, though the latter is preferable, and in this the print rapidly assumes a purple tone and full intensity.

Considering that a faintly impressed image can be obtained on P.O.P. by burning a foot or two of magnesium ribbon three or four inches away from the negative, and the image thus obtained can be developed by either the above processes, there should be no difficulty turning out prints in winter as rapidly, almost, as in summer.

THE SENSITISING ACTION OF SOME YELLOW DYES AND MEANS OF DETERMINING IT.

Those who are interested in orthochromatic photography cannot fail to appreciate the subtlety of yellow dyes as regards their influence on silver bromide emulsions. The number of yellow dyes which are now made are exceedingly numerous, and it is possible that there are many among them, as yet untried, which could be used as colour sensitisers. Their action is in many cases so limited, that it is difficult to interpret one result, but one noticeable point in their behaviour is the relation of their sensitising actions to their absorption; is hardly comparable with that of the blue-black and violet dyes.

The testing of a plate sensitised with a dye is a matter which requires especial consideration, and the illuminant must essentially be the same both for testing and using the plates. The difficulty of employing daylight for work destined to be of any scientific value is of course known to be very great, and a glance at Fig. 1 will show how impossible it would be to estimate the action of a dye by its means. Four curves are given, obtained by plotting the densities of different portions of the spectrum photographed upon the same brand and batch of panchromatic plate. No. 1 is the result when incandescent gas was used to make the spectrograph, No. 2 was made by strong sunlight, No. 3 by a brightly clouded sky, No. 4 by a heavy, rainy sky. The results are markedly different, in the second, third, and fourth curves they do not necessarily show that the light varies in its proportions of pure colours under different atmospheric conditions, though it is generally supposed that this is the case, but they show the impossibility of taking for scientific comparisons or estimations such a changeable illuminant as "daylight."

Imitating the excellent suggestion of Dr. Eder to some extent, the following estimates of the effect of four well-known yellow dyes were obtained by making the spectrographs with a standard illuminant, and resolving the ratio of density in the greenish-yellow region to density in the blue region into a fraction, so that any one dye could be compared with another by comparing their sensitiveness to greenish-yellow against their sensitiveness to blue. The following table was thus arrived at:—

Dye.	A.—Density of Blue Region.	B.—Density of Greenish-yellow Region.	Ratio of A/B.
Aurantia	12.3	1.7	7.23/1
Thiazol yellow	14.5	3.7	3.92/1
Uranine	13.8	2	6.9/1
Auracine	13.8	4	3.45/1
None	9.3	1.9	4.9/1

Such a table as this could of course be made up in endless ways, but it will be found of great use if formulated somewhat in the above way. For example, if experimenting with rhodamine, a yellow and green sensitiser, spectrographs are made of the densities of the bands corresponding to the blue, green, and

yellow portions of the spectrum read, and the ratio of blue sensitiveness to green, blue sensitiveness to yellow, etc., obtained. The lower this fraction is, the more active will be the dye with regard to the region of the spectrum in question. Thus out of the four above described, auracine is clearly the best for sensitising for greenish-yellow, according to the experiments under discussion, it giving a sensitiveness to the E region nearly a third that of the plate's sensitiveness to blue. For the bluish-green region uranine runs auracine very closely especially when used as a neutral solution plus silver nitrate. The same four dyes were also tested in another way, a very useful one for determining the practical value of a dye for various kinds of illumination. One in two thousand aqueous solutions were prepared, and rendered alkaline with ammonia. Plates were bathed with the filtered solutions, and exposed under a Chapman-Jones plate-tester, and all subsequently developed for an equal time. The densities of the colour

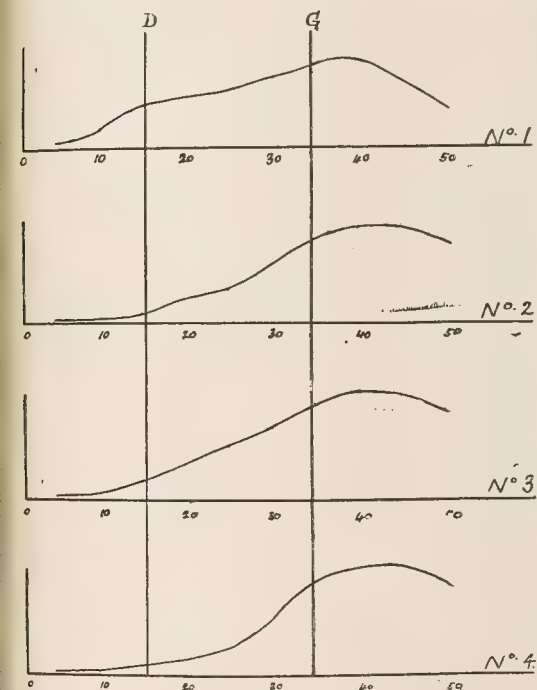

Fig. 1.

patch records, blue-violet, green, yellow, and red, were determined on the photometer, and each tabulated as follows:—

Dye.	Blue-violet Square.	Density of Green Square.	Yellow. Square.	Red Square.
Auracine	27	14.5	1.0	1.75

The results with aurantia and uranine were not to be compared with those produced by thiazol yellow and auracine, but uranine gave slightly increased susceptibility to bluish-green rays—a thing one would anticipate from its fluorescence. But the result with auracine, as tabulated, is very remarkable. It will be seen by examining the absorption curves of the dyes used for these experiments (Fig. 2), that the "colour" of auracine does not differ very markedly from that of aurantia. (At any rate, it is only when one compares the readings of the absorption spectra of extremely dilute solutions that a greater extinction co-efficient is apparent from F to H in the case of aurantia.) And yet these two dyes behave entirely

differently in their sensitising action. With auracine our plate is sensitive to yellow and red, with aurantia no visible sensitiveness is conferred.

Aurantia and uranine were further tested by bathing plates with an ammoniacal solution of each, to which a small quantity of silver nitrate was added. Uranine being a fluorescent dye, and therefore possibly capable of exerting more energy than one non-fluorescent such as aurantia, it might reasonably be expected that the addition of free silver nitrate would effect some increase in its action. That it does so can be shown by means of the spectroscopic camera, the prismatic spectrum being for some reason the best, but with aurantia, silver nitrate works no miracle, and it remains still apparently inert. A reference to page 115 of Hübl's "Dreifarbentphotographie" will show the author's opinion of uranine to be high, and the dye certainly works well with eosin and erythrosine, more particularly when silver nitrate is present also. Its action is, however, uncertain—i.e., it varies with different qualities of plates.

Those to whom a sensitising bath for an "orthochromatic" plate or a plate suitable for the green exposure in three-colour work is of interest will find auracine well worthy of their attention, as in conjunction with erythrosine it is particularly useful for bathing plates. Although mentioned by Dr. Eder some two years ago as a green sensitiser, it does not seem to have been followed up with the interest it undoubtedly de-

Fig. 2.

serves. Like uranine, nevertheless, it is a far more valuable colouring medium when used with erythrosine, enabling a continuous band to be obtained from the blue-violet end of the spectrum up to about D $\frac{1}{2}$ E, on plates bathed with the solutions.

When using silver nitrate with auracine, a thorough rinsing of the bathed plates is necessary before drying them; the quantity of AgNO₃ should approximately equal that of the dye or dyes by weight and lastly, drying should be effected within two hours, and the plates used when fairly fresh.

T. THORNE BAKER, F.C.S.

PROFESSIONAL Photographers' Association.—A meeting of the General Committee was held at 51, Baker Street, on Friday, December 9. The following members were present:—Messrs. Alfred Ellis, A. Mackie, Martin Jacquette, Lang Sims, F. A. Bridge, Wm. Grove, E. Scamell, R. Fellows-Willson, S. H. Fry, and D. Prodger; Mr. Alfred Ellis in the chair. The minutes of the previous committee meeting were read and confirmed. The various suggestions for the improvement of the Assistant's Certificate scheme having been incorporated by the sub-committee, the complete prospectus was considered and passed. The "Handbook" for 1904-5 was also considered, and various alterations agreed to.

THE PRACTICAL PERFORMANCE OF TRI-COLOUR FILTERS.

I.

[Read before the Royal Photographic Society.]

THESE experiments were undertaken with the object of determining the best form of filter for tri-colour reproduction by the half-tone process, for use in the tri-colour instruction classes in the London County Council School of Photo-engraving and Lithography.

The following points in particular were examined as to their effects on the accuracy of the colour rendering:—

Firstly, whether it were possible to work with filters which, in conjunction with their respective plates, should follow certain theoretical curves, such as colour mixture curves or colour sensation curves, to which, according to leading authorities, the opacities of the negative records should correspond, or filters with specially calculated curves for half-tone work as assumed by other authorities. As no one appears to have attempted to make filters which would even approximate to some of these requirements, the only filters of this class which we have been able to use are those made by Mr. Ives for use with the "Kromskop," which we are not sure that he would recommend for half-tone work, although he states the principle involved to be the same.

Secondly, the effects of other maxima, notably those which occur when using erythrosin plates in conjunction with a broad banded filter.

Thirdly, the effect of allowing ultra-violet to be recorded together with the violet.

Fourthly, the effect of the loss of the extreme red light, which is never all photographically recorded in three-colour work.

Fifthly, the effect of certain pure colours not being recorded through any of the filters, instances of which occur in two sets of commercial filters.

Lastly, to determine whether the negative records should be even, and end abruptly, and, if so, the precise extent to which they should overlap each other.

PROCEDURE.

Reproductions were made by the various filters selected of a good hand-painted chart in oil-colours, supplied by Messrs. Winsor and Newton, and possessing great variation of colour and gradation, which we used because it was, we considered, a particularly difficult subject to reproduce. In the indirect method, dry plate negatives were made of this with electric light upon the plates for which the filters were designed; these were developed with glycine by factor development, the exposure and, where necessary, the factor, being altered, so that a black to white scale of graded tints placed on the colour chart was reproduced in exactly the same manner in all the negatives.

In order to accurately determine the precise manner in which the various filters were acting with regard to the colours being recorded, and the variation in the character of the record when working on light and dark colours, a series of sets of exposures were made to a nearly normal spectrum produced by a prism grating. The absolute value of these exposures was made strictly proportional to the camera exposures required for each filter and plate, and the series of exposures were made in the ratios of 1, 3, 9, 27. From these negatives, as well as the chart negatives made by the indirect process, contact transparencies were made upon a plate of medium speed, and from these, screen negatives (175 lines to the inch) were made upon wet

collodion. Some sets of collodion emulsion negatives were also made by the "direct" process, in which the screen negative also gives the colour record. All the screen negatives, either made indirect or direct, have been put on to the metal with the fish glue enamel process and rough etched. In the whole of these operations, and also in the subsequent proving, every effort was made to keep the conditions as uniform as possible. No local intensification or reduction was made on the negatives, no work done on the transparencies, no fine etching on the blocks, or overlaying in the printing. Under these circumstances the final colour prints are not brilliant, but form, according to the faithfulness of the colour reproduction, a good practical guide to the working of the filters. Of course, from very poor filters good results could be obtained if unlimited handwork be allowed, but the value of the filters can only be judged according to the truthfulness of a purely mechanical rendering by their aid.

We are aware that in putting results before you that are absolutely untouched, we may be courting expressions of horror from the appearance of all the proofs, especially from those among the audience who have never yet seen a three-colour proof before fine etching, or even one proved without making ready.

But, we repeat, if handwork be allowed, either in retouching the negatives, retouching the transparencies, in local cutting or otherwise chemically "faking" the screen negatives, fine etching on the blocks, or make ready in the proving, no honest comparison of filters is possible, since with skilful etching and re-etching one is able to make a passable three-colour print from an ordinary monochrome original, in fact many of the three-colour postcards of landscapes now sold are simply made from an ordinary uncoloured photograph. While we admit that we have never yet seen a three-colour that could not be improved by fine etching, still we think that the amount of this now done is much greater than it need be and is mostly occasioned by not sufficiently correct filters and inks, and errors in manipulation.

The proving of these blocks has been done chiefly on a hand press by ourselves, and no doubt better proofs could be obtained by an experienced expert prover, especially on a power machine.

With regard to the printing inks used, we believe that they should be more than merely complementary to the spectrum colours recorded, that is, they ought to reflect all the colours not recorded, for instance, the yellow ink should be a minus blue, viz., a tint composed of the mixed colours of the spectrum, after the blue recorded on the negative through the blue filter has been subtracted, the red should be a tint composed of the rest of the spectrum after the colours recorded on the green filter have been subtracted, and the blue should be a minus red, that is, a tint composed of the colours of the spectrum after subtracting the colours recorded through the red filter. Another necessary condition is that when printed in pairs they must correspond as nearly as possible to the three primary colours—red, green, and blue-violet. But both of these sets of conditions cannot be satisfied at the same time unless the filters are acting in the way which we believe to be correct. With all the commercial filters we have yet seen the first condition must be sacrificed, as it would not be possible to use the true complementary colours to the filter records for printing, because in many cases they would be pale tints.

After examining fourteen makers' sets of inks by printing them in pairs, as well as taking spectra photographs of their absorptions, we found that there was not one set that conformed to the desired conditions, so we have had to select the three best inks, each from a different source.

Taking now a set of spectrum records that we consider are approximately correct, and putting those through the spectrum

and recombining the light left, you have the complementary, and beside it we place the inks we have selected as the best available.

The yellow is Brooke Simpson and Spiller's yellow No. 2,956, and you will see it comes fairly near the truth. The minus green has been made for us specially by Messrs. Fleming of Edinburgh, and they call it "New Process F." They say it is fairly permanent, but it is not an easy ink to work with, being stiff, and soon goes "livery." You will see it is still a long way from correct, but much nearer than most reds. The minus red is Messrs. Shackell Edwards' trichromatic blue, and this also you will see is a long way from theoretical conditions, still, again, it is far ahead of some others. It would appear that the difficulty in the blue ink is that directly an ink is made of the shade desired it becomes very transparent to red, even this ink is far too transparent to red in thin layers, at the same time it is not transparent enough to green.

We have used the same inks throughout, and it will at once be seen that these inks are not truly complementary to all the filters, but in most cases it would be impossible to find a complementary nearer, that would at the same time give anything approaching a black when the three inks were superposed, or the primary colours when superposed in pairs. Lamière's filters certainly require a lighter yellow, but otherwise we do not think that by making the inks more truly complementary there would be any all-round improvement; the reproductions might be better in places, but they would be worse in others.

We have carried out these tests with twelve different sets of filters, viz., those of Mr. Ives, Mr. Sanger Shepherd, Messrs. Lumière, Messrs. Farmer and Symmons, Mr. Klein, and others which were made at Bolt Court. Of course, all reproductions, both of the chart and spectrum, have been made by electric arc light using direct current, and, while up to now we have obtained the best results before fine etching by the indirect process, we cannot but recognise that this way of doing ordinary small-sized commercial work in the studio where the screen cameras and powerful arc lights are available, is doomed. The introduction of the new dyes, orthochrome T and pinachrome, make process plates after bathing at least as good as, probably better than, any commercial orthochromatic plates for colour rendering, and certainly much better for ability to give a dot effect on a dry plate suitable for easy printing on the metal.

A set of filters, similar to the best we shall show, can be constructed for direct dry-plate work, with excellent results, the best procedure in our opinion being to use a Commercial half-tone plate,* with quinine for the blue filter, and the same plate previously bathed in a solution of pinachrome and then well washed and quickly dried, for the green and red exposures.

The exposures on the chart on an Ilford half-tone plate, bathed for the green and red with pinachrome, totalled less than twenty minutes, which, considering the small stops used and that the cross-line screen cuts off about three-quarters of the light, is remarkably quick.

Collodion emulsion, used in conjunction with the screen and colour filter, is already in very common use, but with the sensitisers hitherto available it has always been very uncertain and troublesome with regard to speed, colour sensitiveness, and clean working. Sensitisers containing silver, as for example Albert's A added to the emulsion, invariably cause it to go foggy after a short while, the makers refusing to guarantee it longer than twelve hours, and the least dust or disturbance from almost ideal conditions gives rise to a plentiful crop of spots. Messrs. Meister, Lucius, and Bruning have, however, introduced a dye called "pinaverdol," which contains no silver,

but confers an almost even green sensitiveness, a great increase of speed (which, however, largely disappears with long keeping), and no tendency whatever to go foggy, so far as we have been able to see. The emulsion does not attain to its full quality immediately after it is sensitised, but does so when one day old. The plates must be washed well (say, two minutes) before exposure. This considerably accelerates the speed. The emulsion also lends itself to sensitising very readily to the red farther than any dry plate, either by the addition of Penrose C sensitiser or by taking one part of a solution of ethyl violet (1 to 500 alcohol) to 50 of plain emulsion. This also does not fog the emulsion, but it does not attain to fullest speed at once; on the other hand it does not deteriorate with age. This also must be washed thoroughly before exposure, otherwise it will work very slowly. The washing is really no disadvantage, as it enables the plate to be kept moist for a considerably longer time, and then has not to be done before development.

With regard to filters other than our own, in every case the plate recommended has been used, while for our own indirect work we have chosen plates in accordance with our set of comparative plate tests shown at this Society last October. From those we decided that the best commercial plate to use for the red filter (blue printing plate) was the Lumière C, on account of its going farther into the red than any other plate so far on the market, and needing least exposure under a red filter. The best for the green filter (red printing) was the Cadett spectrum, being the only plate then on the market having an even sensibility to green, though since then the new Mawson B is very nearly as evenly sensitive and equally as good as the spectrum under a green filter, and we have found this plate a little easier to work in regard to freedom from fogging and the attainment of good density. An ordinary plate does for the blue filter; we have used as a rule Mawson and Swan's Castle plate.

Some authorities maintain that panchromatic plates are essential, but we have tried the chart on commercial and bathed panchromatic plates, and do not find any advantage in using a panchromatic dry plate for the yellow printing plate; an ordinary plate does just as well if the same gradation in the black and white strip that is always first attached to the original is attained, and by giving the correct exposure and developing with the correct factor, this is possible of accomplishment. Panchromatic plates would be necessary if the argument be correct that the yellow printing negative should record the extreme red, but it is not. This idea has probably arisen from a consideration of the colour sensation (or mixture) curves, but there is no blue filter that we have ever handled, or even seen described, that in practice would record the extreme red during a normal exposure or before the blue was overexposed, and a little reflection will show that for two reasons the blue filter ought not to record the extreme red. For, in the first place, this would need that the red ink should print alone in the deep red, while the correct complementary red to the green filter is a distinctly violet or pinky red—far from a deep red. With a deep red it would be extremely difficult, if not impossible, to match certain colours (e.g., pinks), and, secondly, since yellows in nature are made up of green and red light, it would be found that yellow would record to as great an extent as the red, and prevent it being the least opaque part of the negative, as it should be with the blue filter.

"Toning Bromide and Other Developed Silver Prints," by R. E. Blake Smith, is the title of the latest of the "Photography Bookshelf" series of handbooks, which has just been issued by Hiffe and Sons, and it deals in a thoroughly practical manner with the various methods that have been suggested for modifying the colour of bromide prints.

* We used the Ilford "Half-tone" Plate.

"ONE MAN METHOD."

[Abstract of an address before the Convention of the Photographers' Association of America.]

I BELIEVE in and use a "One Man Method" in conduct of photographic business, just the same as does the painter, sculptor, physician, dentist, and every other of the men who follow as a business art or science and expect their results to be ideal. During my talk I shall touch upon five vital points. First, the advantage of system; second, the successful use of artificial light developing papers; third, the elimination of necessity for retouching; fourth, the avoidance of re-sittings; and fifth, the lever for better prices and increase of income.

"System will move the world"—an old time saying. It will move a world of photographic business; I am now doing four men's work with ease. When I begin to develop the method I now use and teach, Sundays, holidays, and evenings, as well as my day time, found me at work. Now each day discovers some newly-found opportunity to save time, possibly minutes, may be seconds, the endeavour to save time and get improved quality being the impetus prompting my continual endeavour so to do. Add together these minutes and seconds during nine years of constant endeavour to save time and the result is not so surprising. I am each year doing more and better work in less time and at less cost, while prices advance. There is but one possible deduction as to cause system. Not only in the endeavour to shorten time by the discovery of more rapid means, but in a convenient arrangement and the use of good judgment, is system acquired. There should be a place for everything and everything in its place. I print, develop both negatives and prints, and even mount in my dark room, and can reach everything therein without a step. I also know that failure to dust plates before exposure and before development means more time spent on the prints. If the negative is not right in quality time will be required to correct the fault. I think ahead and save time and trouble.

System in the business end is just as necessary. Few of us realise this. Some methodical routine procedure for the business part should be established to suit your conditions and your public and strictly adhered to. Endeavour to systematise in both the working and the business ends of your profession and it will surprise you in its time-saving and money-making results. I have not time to detail advantages in the use of system. The fact of its desirability is apparent to everyone. My idea of a "One Man System" is sometimes misunderstood, as evidenced by the following: A German woman servant called for the portrait order of her mistress. Several friends were in my operating room at the time. Being busy at my work one of them volunteered to meet the customer. Another offered to take the portraits into her, and I shortly followed into the reception room to collect the balance due. As she started to the elevator, the girl said: "Mr. Vaide, I like your von man metod; I have heard of it; I will come here for my picture soon. Your metod is a good von. You have von man to meet you, von man to give you the pictures, and von man to take the moneys. I like your von man metod."

The time limit for my address allows but few suggestions for successful use of artificial light developing papers. Carbon and platinum effects, with their beautiful tonal values, are uniformly possible with these papers. This fact cannot be questioned. Once obtained they must be in the product. The amateur occasionally gets them, why not the professional, and always? The secret is primarily in the negative. The general density must be thin, but it is the relationship of highest lights to deepest shadows that counts. A brunette with black crushed velvet gown, trimmed in white, wearing white hat with white plume, must, as an example, be so treated that after screening down the high lights to a low enough key, prolonged development and exposure for full detail in the deepest shadows will not block the high lights, they being transparent enough to read a newspaper through them. Subject is placed away out under the light; screen (which is the real skylight and is covered with both white and black curtains each but twelve inches square and running on wires) is placed close to the subject—it being known that the movement of a curtain on the skylight far away alters the entire effect. The screen curtains are manipulated until high lights are down to a very low tone. A grey reflector, if needed for the shadow side, is so placed as to illumine the shadow side, but not to project false light. A plain grey background is placed and is shaded on side next to the skylight by placing an opaque covered frame at right angle with the ground and

moving it until the ground is sufficiently shaded to show the lighted side of the subject in some contrast with the background. Quality of negative depends upon screening, exposure, and developer used. I believe in long exposures. Time will not allow the telling of all of my reasons therefor. By conversation during the exposure, the thoughts in the mind of the subject produce a movement of facial muscles (little lines of drawing), which gives a softening effect, lessening need for retouching, and a composite of expressions, besides a better effect of the eyes, the screening allowing the pupil of a light eye to expand, thereby improving expression. Nervous people and children require, of course, shorter exposure and must be placed farther back under the light and less screened; but result is not so round in perspective or pleasing.

I believe, in use of head-rest where possible. Many disagree with me on this, I know, but I would rather get better results and use it than the reverse. I never have an objection raised by a patron. It is placed with the remark, "This is only temporary and will soon be removed," continual conversation thereafter causes forgetfulness of the head-rest and its use is not noticed by the subject. Try this plan.

I now expose for the deepest shadows, and with a developer, which I use for both plates and prints—half and half of metol and hydrochinon, and very much diluted—develop for the detail in deepest shadows, knowing that continued development will not make a single high light too dense. If negative needs more snap after detail is all out, a "coaxer" (made of full strength developer, old developer, and plenty of bromide) is used, and in a few seconds acts on the highest lights. Negative must be thin when fixed out, and the relation of high lights to shadows, so hurriedly explained to you, must exist.

In making prints from such negatives, I place in a small porcelain dish a few ounces of fresh developer and a piece of cotton (not absorbent), and expose this print to a light (three incandescent burners—over them a mirrored reflector, the illumination softened by a sheet of tissue paper, all in a 24 by 24 by 24 inch box)—and after placing the exposed print, while dry, on a sheet of glass, go over it rapidly until developed. If development is too long, and print has no strength, or yellows, expose longer; if too black, expose less; if too grey, add bromide until the whites are clear. Lack of time renders impossible a more detailed and thorough description of this process. I use for a hardener solution for both print and plate fixing bath the following, and I add one ounce of it to every gallon of hypo solution: 15 ozs. acetic acid, 2 ozs. sulphite sodium, 2 ozs. powdered alum. Uniform carbon qualities are actually obtainable with gaslight papers; they are in the product; they are difficult to obtain until once the thing is understood, and then it becomes the easiest process imaginable. These papers are the coming thing.

Negative quality, which I obtain, and that you can get, needs little retouching. You do not need a retoucher in your place. I am not a retoucher—could not retouch if I tried. There is but one thing to learn, not how much to retouch, but where not to retouch. Avoid its necessity by the right negative. Work usually necessary to eliminate defects which appear when a print is for a long time exposed to daylight will not register on paper prints under such conditions as I have outlined. I wish I had more time to go into detail and reasons. Learn where you must not put your pencil, and the likeness is never changed, the modelling is perfect, and flattery comes from lighting and timing and development, and not in the retouching. Time flies, and I can but touch on the subject of avoidance of re-sittings.

I make several negatives of each patron, having obtained in advance their approval of my idea of leaving to me the experiments until they see what they can get. I proof all the negatives roughly, darkly, making them as unflattering as possible. Selecting the best, I retouch them for finished portraits (the little retouching required does not take long). If a fault appears I correct it and reproof until perfect. A criticism once found can be altered, but never eradicated. The proofs I wish to be ordered from must be better than any they have ever before received, as perfect and flawless as the picture; right there the battle is won. I have had but three re-sittings in three years' business in New York City with my exacting Fifth Avenue clientele.

Lever for better prices and increased income. I invariably make one or more large plates of each patron; if the order is to be but for a locket I make at least one 8 by 10, and if the plate is deserving I show a proof of it as perfect as a finished print. It took me until a few years ago to realise the profit by religiously following this plan

every patron. Try it faithfully, not for one month, not three months, not six months, but for a year; then figure up and see where you stand on the proposition. Try it. Whether you are in little or in towns, just try it. The income therefrom for the year will vastly surprise you. If the large plate is not good enough, do not show it. If it is worthy, someone will want one or more prints therefrom. That much is your income-increased.

Better prices follow immediately the production of your own mounts, folders, and effects. Your own individuality, like that of the painter or sculptor, appears in your product, and no one will say to you, "I saw the same thing down at Smith's for so much per dozen."

In developing your One Man System aim for a cheaper material if the desired effect follows, for economy is a money maker as well as is increased prices. I am using the cheapest of everything to be obtained. I get carbon qualities and prices for results. It costs the physician to write a prescription. His pay is for the know how.

MILTON WAIDE.

POTASSIUM BROMIDE AS THE INDIRECT CAUSE OF DICHOIRC FOG.

LÜPPO-CRAMER continues in the "Photographische Correspondenz" his researches on the theory of photographic processes, and writes his current notes to the above subject, and introductorily remarks that dichroic fog so often occurs in practice under conditions in which the ordinary explanations are quite unsatisfactory, that he has led to examine the subject more closely.

As when an acid fixing bath is used the reduction of any dissolved silver bromide by the traces of developer, remaining in the gelatine after development cannot take place, and, on the other hand, the other solvent of silver bromide used is thiosulphate of soda, and only in very minute quantities, there must be certain conditions under which the sulphite is the solvent. In his last note on this subject he pointed out that with certain dilution of the developer the latent action of the sulphite came into play and gave rise to dichroic fog.

It is often said by practical men that large quantities of potassium bromide in the developer, particularly with bromide paper, can produce yellow fog. Few statements could be found in technical literature on this point, though it seems generally well known. Andresen states in his "Chemie der organischen Entwickler-substanzen,"¹ that with certain developing agents of the naphthaline series the proportion of potassium bromide favoured the formation of yellow fog. The said experimenter is of the opinion that this kind of yellow fog is dependent on the poor keeping power of the developing solution, and it almost appears that "dichroic fog" is not meant. Hüllner von Hübl mentions in his book "Die Entwicklung, etc." (1. Aufl., p. 54) that with the exception of glycine a larger quantity of potassium bromide results in yellow fog. Lumière and Seyewetz² on the other hand state "that alkaline bromides appear to be without influence on the formation of (dichroic) fog." In my first work³ on dichroic fog I found this latter statement so far confirmed in that small quantities of bromides did not prevent the occurrence of dichroic fog that was caused by solution of the silver bromide by specific additions of the developer of fog-producing agents, such as the sulphocyanides. The following experiments prove that the formation of dichroic fog is the result of solution of the silver bromide by sulphite, can be directly or actually caused by potassium bromide.

If an unexposed dry plate is developed for twenty minutes in the following developer: hydroquinone 2g., anhydrous sulphite 10g., water 100ccm., mixed with an equal volume of 10 per cent. solution of soda, and 50ccm. and 200ccm. of a 10 per cent. potassium bromide solution is added, with the former strong dichroic and chemical fog is formed, but the dichroic and not the chemical fog with the latter. Pyrogallol and adurol (chlor-hydroquinone) gave under the same conditions 100ccm. K Br still stronger fog, edinol and glycine considerably weaker fog. Pyrocatechine gave, even after twenty minutes' development, no yellow fog, with metol it was only obtained with very

dilute developers, such as 100ccm. of soda 1 : 10 to 200ccm. of metol solution and 100ccm. of potassium bromide and three-quarters of an hour development. A comparative test of this metol developer and the above-mentioned hydroquinone developer was very instructive.

The developing power on the latent image was approximately the same for both solutions. After fifteen minutes' development the image in the metol solution was without any trace of dichroic fog, that in the hydroquinone developer was covered with an intense dichroic fog. Hydroquinone-soda compared with pyrocatechine-potash, with 20ccm. of K Br solution to 200ccm., and with obviously analogous composition, have almost the same developing power.⁴ Yet in the pyrocatechine there was only a faint yellow fog after half an hour, whilst with the hydroquinone a very dense red fog was formed. It must be noted that in all these cases we had to deal with finely divided metallic silver and not with the oxidation products of the developing agent. The appearance of the dichroic fog is, from the above experiments, undoubtedly influenced by the nature of the developing agent, independently of its reducing power on the latent image, which accords with Hübl's statement, quoted above, that the yellow fog so often observed is a property peculiar to hydroquinone, whilst his other remark that glycine never gives rise to yellow fog requires modification.

The tendency of the various developing agents to form dichroic fog, which differs so enormously with approximately equal developing power, appears analogous to the different tendency to the formation of the ordinary chemical fog with equal reducing power on the latent image, which is the case with the developing agents in use, and still more so with a class of bodies, which, according to Andresen, only develop the latent image with difficulty and yet give chemical fog.

The explanation of the action of potassium bromide in the appearance of the dichroic fog in the above-described experiments, it should first be mentioned that the bromide itself as the result of a solution of the silver bromide, does not cause the phenomenon. In a glycine developer, devoid of sulphite, no fog was caused; even with such a large proportion of bromide, whilst with sulphite it did occur. For such a comparative test glycine is very suitable, as without sulphite it does not give oxidation products which stain the gelatine, which might, as with hydroquinone, disguise the dichroic fog. The bromide salt thus obviously only acts indirectly, as it strongly retards the ordinary reduction of the latent image and the formation of chemical fog, and therefore gives the sulphite sufficient time to dissolve the silver bromide, so that the slight direct influence of the bromide on the formation of dichroic fog makes itself felt.⁵ As I have previously mentioned, different makes of plates show very different behaviour as regards the tendency of dichroic fog, and this difference makes itself distinctly noticeable in the case of the fog indirectly caused by the bromides.

MR. JOHN H. AVERY now represents Messrs. Wellington and Ward in London and greater London. Mr. Avery informs us that he is prepared to give his lecture on "Morocco" before any of the London societies, and would be glad of dates as soon as possible. His address is 108, Saverlake Road, Hampstead, N.W.

THE Civil Service Motor and Cycle Agency, Ltd., of which the Service Photographic Society is a branch, have just issued their annual balance-sheet, and from which we learn that the trading for the twelve months ending September 30, 1904, has shown a gross profit of £4,279 2s. 1d. (comparing with £3,839 10s. 1½d. in the previous year), and a net profit of £823 3s. 8½d. Deducting the amount already paid as interim-dividend on Preference holdings of £50 and upwards, there remains a balance of £757 3s. 9½d. to be disposed of, which the directors propose to devote to the payment of the balance of the dividend on the Six per Cent. Cumulative Preference and the Seven per Cent. Preferred Ordinary shares, to pay 5 per cent. on the Ordinary shares, and to carry forward £93 14s. 1½d. (subject to deduction for income tax). The reserve fund, to which has been added the premiums received on the new issue of Preference shares, now amounts to £1,043 11s. 0d.

WHAT MAKES A PHOTOGRAPH UNFIT FOR PUBLICATION?

THIS question was recently set by our American contemporary, "The Camera," as a competition, and the following was the most satisfactory reply received, and the author, Mr. Ernest Rohner, says:—

"I intend to treat the subject successively under three different phases—namely, reproduction from art studies of the nude, ambiguous pictures, and obscene pictures.

"It is, indeed, to be deplored that, with many people, the æsthetic sentiment along some lines is so little developed as to permit the art works of the nude to become offensive to them. However, we will take due consideration of the meaning tacitly implied by the words of the question for publication in an ordinary newspaper. As the mass of the readers of the daily newspapers present the most heterogeneous conglomeration as to age, education, and views, the manager of a daily newspaper must therefore use the most delicate judgment in the selection of pictures intended for publication. On the other hand, we see that the publishers of art journals enjoy far greater liberties, their field being practically unrestricted by the nature of the subject. We find, therefore, these journals to present to their readers, who are the refined and higher educated exclusively, subjects which would, in many cases, be unfit for publication in an ordinary newspaper. Now, art journals, as a rule, do not get into the hands of children; but how many of the hundreds and thousands of little ones do not glance over the pictures published in the daily newspapers? Children, with little experience to guide them, with minds yet in a primitive state of development, are most apt to misunderstand and misinterpret things. Well and fully justified is therefore the discretion of the newspaper manager, exercised along these lines.

"Ambiguous pictures: I am aware that it is not customary to use the word in this connection; however, the term is expressive of the very character of a special kind of pictures. As ambiguity renders the meaning of a speech doubtful, so may it serve to obscure the *motifs* of a picture. This class includes pictures which, under a more or less clever disguise of an artistic nature, suggest, by the costumes and poses of their figures, meanings and actions offensive to chastity and modesty. They minister not to our higher feelings, as the works of art always do, but are intended to gratify our senses only. The cowardice of their disguise makes them contemptible and the baseness of *motif* utterly despicable. See the difference between art and these pretensions! Experience the ennobling influence of a statue of Venus, as its beauty and symmetry of form enchants us; of an Apollo, as its strength grows upon us. Experience, then, the disgust produced by pictures of the ambiguous kind. These pictures vary, of course, in degree of comparative unfitness for publication. For instance, an extreme low-cut evening dress, permissible as it yet may be, cannot but be considered as a distinct antecedent of a sight or a picture decidedly vulgar and disgusting.

"The very character of pictures of this class makes them unfit for publication.

"In obscene pictures not the least effort to disguise their vulgarity is made. They boldly stand for what they are, an affront to delicacy, purity, and decency. We have certainly no consideration for them.

"As a summary, I would say: Good pictures minister to our higher feelings, offering to the healthy mind a healthful pleasure. But pictures appealing to the passions or the sensual feelings are debasing in their effect, and are therefore seldom or never fit for publication—least of all in an ordinary newspaper."

THIS month's issue of the "Optical Lantern and Cinematograph Journal," just to hand, is a bright and readable little production. It is edited by Mr. Theodore Brown, of Salisbury, and published by Heron and Co., Tottenham Street, W.

X-RAYS Used on Oysters.—Pearl fishing in Ceylon has been greatly assisted (says the "Board of Trade Journal") by the X-rays. Their application enables the fishermen to discriminate—and throw back into the sea—oysters of no commercial value. Unless the "Board of Trade Journal" had told us, we were not aware that fishermen were so considerate of what they caught that was not of immediate value to them, or that they carried with them, even in pearl fishing, an X-ray outfit.

ANNUAL REPORT OF ILFORD, LIMITED.

THE following is an extract from the directors' report for the year ended October 31, 1904, to be presented at the eighth ordinary general meeting to be held at Winchester House, Old Broad Street, E.C., on Tuesday, December 20, 1904, at 12 noon:—

The directors beg to report that after payment of working expenses directors' fees, income tax, etc., and making allowance for depreciation and provision for doubtful debts, the net profit for the year's trading is £25,496 14s. 6d. This amount, with £3,254 2s. 6d. brought forward from last year, gives £29,750 17s. for appropriation. It was strongly recommended by the Shareholders Committee in 1903, and approved by the shareholders in general meeting, that the smaller rates of discount allowed by the Company should be made comparable with the much higher rates given by other manufacturers. This has been carried into effect by the directors, with the anticipated result of a considerable reduction in profit, which accounts for the above diminished amount of appropriation. The new factory at Warley commenced work last March, and in consequence of a large number of new hands having to be educated to the work, besides other charges incidental to starting a new factory, the working expenses this year are abnormally high.

The directors have paid an interim dividend on the Ordinary share capital for the half-year ended April 30, 1904, at the rate of 8 per cent. per annum, absorbing £7,600; and for the same period they have paid the dividend on the Six per Cent. Preference Shares, amounting to £5,700. Since then the second dividend on the Six per Cent. Preference shares has been paid. From the balance, £10,750 17s., the directors recommend that £5,000 be written off goodwill, processes, etc.; and, on account of the exceptional expense incurred this year in connection with the Warley factory, they recommend that £4,000 be taken from the reserve fund, which will place £9,750 17s. for disposal. From this the directors recommend that a dividend be paid on the Ordinary share capital for the half-year ended October 31, 1904, at the rate of 8 per cent. per annum, making, with the above interim dividend, 8 per cent. for the year. This will absorb £7,600. On this dividend, by the terms of the profit-sharing scheme, £67½% more or less, will be paid as bonus to the employés. The balance, £1,480 17s. will be carried forward.

The necessity of transferring several employés from Ilford to Warley, where it was impossible to find house accommodation for them, has led the directors to approve a scheme for erecting cottages on a portion of the Company's vacant land there, which is never likely to be required for factory purposes, and nineteen cottages have already been built. Notwithstanding the fine summer, the photographic trade in this country, like all other trades, has been severely depressed, but the Company's sales for the year are only a small percentage less than last year; and, for the past seven months, they have shown a satisfactory increase over the corresponding period of the previous year. The directors regret that early in the year, owing to ill-health, Mr. A. H. Harman resigned his seat on the board; after full consideration they have decided not to fill up the vacancy. One director, Mr. J. Kemp-Welch, retires this year from the board, and being eligible, offers himself for re-election.

VERY Up-to-Date Method.—With a directorate greatly strengthened by recent additions, the North Borneo Company gave its usual annual dinner at the Hotel Cecil last week. It is always a novel event. The guests smoke North Borneo cigars and drink North Borneo coffee, both excellent. They have annually an exhibition of bioscopic views of North Borneo, for which purpose the company specially commissions the Urban Bioscope Company to visit the country. This is an excellent investment, for, as the managing director, Mr. W. C. Cowie, last night stated, the exhibition last year thereby produced half a million of extra capital.

Exhibition.

REDHILL.

The sixth annual exhibition of the Redhill and District Camera Club was held on Friday week. The judges, Messrs. F. Hollyer and W. Cotton Winter, R.B.A., made the following awards:—

Class I.—Pictorial photography, for members only. Section A (open to all members): Medals, Sir Hanbury Brown, Miss J. Reid, and E. E. Robinson; certificate, J. O. Grant. Section B (open to amateurs only): Certificate, W. J. Prikler. Class II.—Portraiture (open to members only): No award. Class III.—Photographs, illustrating the use of photography for purposes other than pictorial, such as topographical, scientific, record work, etc.: Medal, G. E. Priestly. Class IV.—Lantern slides, for members only. Section A (open to all members): Medal, Miss J. Reid. Section B (open to amateurs): No entries. Class V.—Pictorial photography, open to amateurs resident within a radius of eight miles of the Market Hall, Redhill. Section A (open to all amateurs): Medal, Sir Hanbury Brown; certificate, T. Hakdane Harrison. Section B (open to amateurs): No award. Class VI.—Photographs, illustrating the use of photography for purposes other than pictorial, such as topographical, scientific, record work, etc. (open to all within eight miles radius): Medal, Sir Hanbury Brown. Best picture, irrespective of class: Silver medal, Sir Hanbury Brown.

FORTHCOMING EXHIBITIONS.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 12-17.—Sefton Park Photographic Society, Liverpool. Hon. Secretary, H. E. Cubley, 3, Langdale Road, Sefton Park, Liverpool.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. C. Kimber, Oakdene, Highfield, Southampton.

December 23-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 12-14, 1905.—Boston Camera Club. Hon. Secretary, H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 38, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Mitchell, 180, Browning Road, Manor Road, E.

January 23-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 16-18, 1905.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 25-March 4, 1905.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11, 1905.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14, 1905.—Brentford Photographic Society. Hon. Secretary, F. M. Read, Ferndale, Clifden Road, Brentford.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parham.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E..

New Apparatus, &c.

The "Vril" Vapour Lamp. Sold by W. Watson and Sons, 313, High Holborn, London, W.C.

This is an ingenious lamp specially designed for the enlarging and the optical lantern. The lower portion forms a reservoir for methylated spirit, and is provided with a very small wick lamp by which the oval container, seen at the back of and below the reflector, is gradually heated, and as this is filled with a loose cotton mass which is kept constantly saturated with methylated spirit by capillary attraction from the reservoir, the spirit is vaporised and issues from the burner, which is of the normal type, and thus raises to incandescence the mantle.

The chief features of the lamp are its extreme portability, the absence of rubber tubes or loose parts, and that the whole is contained inside the working lantern, and is further sent out fitted to a tray and rod, so that it may be adjusted to the axis of the condenser.

It is compact and simple in use and thoroughly efficient, and will be found of great convenience for both optical projection and enlarging, particularly in those districts where gas is not available.

The Thornton-Pickard Studio Shutter. Sold by the Thornton-Pickard Manufacturing Company, Altrincham.

This shutter has been specially designed for studio work, and possesses some excellent features which render it particularly suitable for the photographing of children, animals, or other subjects requiring absence of noise and conspicuousness. When fitted inside the camera or at the back of the lens, which is the best place for it, it can neither be seen nor heard. It is operated by the usual pneumatic release, the tube of which is fitted with an ingenious tap so that prolonged exposures may be given or the shutter kept open for focussing. Another good feature is that it opens from and closes to the centre, thus giving a full exposure over the whole of the plate.

The construction and workmanship are, needless to say, of the high character which we always associate with the makers.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
19.....	Society of Arts.....	<i>Musical Wind Instruments.</i> Mr. D. J. Blackley.
19.....	Southampton Camera Club.....	The Exhibition Lantern Slides and Presentation of Exhibition and Club Awards.
19.....	Luton Camera Club.....	<i>Lantern Slide Making.</i> Mr. John H. Gear, F.R.P.S.
19.....	South London Photo. Society.....	Excursion, Lantern Slide, and Print Competitions.
19.....	Bowes Pk. and Dis. Ph. Soc.	<i>The Societies Outings.</i> Mr. F. Cardozo, Hornsey.
20.....	Society of Arts.....	<i>Street Architecture.</i> Mr. Thomas Graham Jackson, R.A.
20.....	Nelson Photographic Society.....	Coinc Camera Club Visit to Nelson.
20.....	Glasgow Southern Photo. Assn.....	<i>R. & J. Beck's Novelties in Hand Cameras and Lenses.</i> Mr. Wm. F. Slater, F.R.P.S.
0.....	Hackney Photo. Society.....	<i>Architectural Photography.</i> Mr. H. W. Bennett.
20.....	Border City Camera Club.....	<i>Principles of Composition.</i> Mr. Geo. H. Hill.
20.....	Architectural Assn. Cam. Club.....	<i>Photography for Architects.</i> Mr. Arnold Mitchell, F.R.I.B.A.
21.....	Blairgowrie and Dis. Ph. Assn.....	<i>Manuscript Magazine.</i> Mr. L. Falconer, Jun.
21.....	Boro' Poly. Photo. Society.....	Latest Date for Receiving Slides and Prints for the Exhibition.
21.....	North Middlesex Photo. Society.....	<i>Elementary Photographic Chemistry.</i> Mr. W. Taylor.
21.....	G.E.R. Mechanics' Institution.....	<i>Instant Photography.</i> Mr. H. Main, B.Sc., F.E.S.
21.....	Cricklewood Photo. Society.....	Beginners' Night.
22.....	London and Prov. Photo. Assn.....	<i>Notes.</i> Mr. T. E. Freshwater, F.R.P.S.
22.....	Hull Photographic Society.....	<i>Neatide Making.</i> Demonstrated. Mr. J. Hollingworth, M.R.C.S.
22.....	Southport Scientific Societies.....	<i>Women's Beauty and its Influence.</i> Mr. C. H. Brown.
22.....	Rodley and District Ph. Soc.	Y.P.U. Members' Portfolio.
22.....	Batley and District Photo. Soc.	Members' Lantern Slides.
22.....	Watford Camera Club.....	Informal Meeting.
22.....	Richmond Camera Club.....	Paper by Mr. L. P. G. D. Taylor.
23.....	Wakefield Photo. Society.....	<i>Kirkstall Abbey.</i> Mr. C. B. Howdill, A.R.I.B.A.
23.....	Aberdeen Photographic Assn.....	Exhibition—Scottish Federation Prize Slides for 1904.
23.....	Watford Photographic Society.....	<i>Some Holiday Lantern Slides.</i> Miss Kate Smith and Mr. C. R. Girardot.

ROYAL PHOTOGRAPHIC SOCIETY.

A PAPER was read at the meeting held on Tuesday evening last, December 13, by Messrs. A. J. Newton and A. J. Bull, in which they record the result of further tests of orthochromatic plates and colour sensitizers. In the absence of the illustrations projected as actual spectrum records a detailed report of the paper can possess little value, but it is interesting to note that in the series of experiments on which the exhibited results were based the authors have attempted to remove a source of error in ascertaining the comparative speeds of the colour-sensitive plates. Instead of exposing plates behind a Chapman-Jones screen until a certain number just shows when developed in a certain empirical way, viz., with a glycine developer, using a factor of six, they now make a series of graded series of exposures the basis of comparison, thus taking account of the gradation which the plates are capable of rendering. In doing this they expose through a graded engraving-black carbon transparency to an acetylene light placed 2 metres from the plate and coming through an aperture 5 millimetres in diameter. By varying the exposure and the development factor it was found possible to bring the various plates fairly closely into line so far as rendering the graded scale in the same manner. A series of figures having been obtained in this way to represent the relative speeds of the plates under these particular conditions, exposure to the spectrum of a prism grating were made in the proportion to the speed numbers. The spectrum exposure was indeed fourfold, the plate being exposed four times in the ratio of 1, 3, 9, and 27. The same factor was used in the development of the spectrum test as was found necessary in the case of the speed trial.

In addition to the examination of a number of commercial plates, the authors undertook the comparison of a series of sensitizers applied to the plate by bathing in the case of gelatine emulsion, or by addition to the emulsion in the case of collodion. The dyes examined included those already on the market, such as pina-

chrome, pinaverdol, and homocol, as well as others which at present it was, stated, are not commercially obtainable, e.g., katchron and pericoll.

In the discussion Mr. Kenneth Mees criticised the use of the spectrum as a test of practical value in the comparison of plates. However valuable it might be for certain purposes, the exposure of the plate through three filters of definite composition would supply all the information which was required for practical work, and the examination could be made so that different workers could reproduce the tests of others.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

An interesting announcement was made by the secretary at a recent meeting of this society. He said it had been well known that the executive hoped to total a membership by the end of the year 200, but he was pleased to report that, a month ahead of time, the numbers were now 203. This statement was received with cheer as was the further announcement that from next January the ordinary meetings of the society would be held in the larger Collyer Hall, the present smaller hall being used for elementary evenings. The occasion was the annual Lecturette Competition, and Messrs. Tryhorn and Gore, of the West Surrey, had kindly come down to act as judges. The conditions were that lecturettes might be on any subject, but should not take more than fifteen minutes in delivery. Six competitors entered, the medal going to Mr. F. W. Jeffery for a lecturette entitled "Odds and Ends from an Amateur's Bag." Mr. J. O. Gardiner, the excursion secretary, took second place with a series of slides illustrating the society's excursions for the past three years. As usual in competitions of this sort, the slides were of unequal merit, and the judges strongly advised that members should content themselves with fewer slides and aim at a higher quality. In all the sets submitted there were several slides which might with advantage have been omitted, as their presence only served to bring down the average of the set. The judges were also rather severe on the literary quality of some of the lecturettes.

CROYDON CAMERA CLUB

INTENSIFICATION by bleaching, with an acidified bichromate salt, followed by redevelopment, was brought forward by Mr. Sellors last week, who dealt with the subject in a very complete and able manner.

The process as a method for reducing contrast, and also as a cure more or less, for halation, has long been known, thanks to Eder, but as a method of intensification pure and simple it was left for Mr. J. S. Teape, and following him Messrs. Welborne Piper and Carnegie, to recently bring it prominently to the attention of photographers. Messrs. Hurter and Driffeld, however (as was pointed out by Mr. Mees), without claiming any originality, in 1898 showed that an increase of density of 25 per cent. would be obtained by the method in question; and, speaking from recollection, MM. Lumière and Seyewetz in 1900 again drew attention to the subject. But irrespective of all claims as to who originated the idea, Mr. Sellors said there was no doubt the process was simple, sure, and generally satisfactory. The negative to be intensified is first bleached in the following bath:—

Potassium bichromate	10 grains
Hydrochloric acid	5 minims.
Water	1 ounce.

It must then be thoroughly washed to remove all traces of the bichromate salt, exposed to any bright light for a short time, and then re-developed with any ordinary developer, and again washed and dried. All operations can be conducted in artificial light, weak daylight, but too bright a light was to be avoided, as having tendency to cause stains. He had tried using the bath at high strength, allowing further time for its action, with precisely identical ultimate results, but had as yet made no experiments as to varying its relative proportions, which had been stated to alter the result. Pyro gave a markedly greater intensification than the more modern developers owing to the non-actinic character of the image.

Turning to the subject of "halation," Mr. Sellors showed that by bleaching the image, followed by partial re-development, and the fixing in the ordinary hypo bath, those parts of the film nearest the glass, where halation showed most, were dissolved out. He preferred

weak developer, so that the right moment to stop could be more easily gauged. Should the negative be too thin after it came from the fixing bath it could be brought up to correct printing depth by re-bleaching and re-developing.

In the discussion which followed, Mr. Mees said, in reference to partial re-development as a cure for halation, he could not agree a weak developer was best for the purpose. A weak developer could not be assumed to even approximately travel through the film, reducing as it went; a dilute developer, as a fact, might traverse the film entirely before development started. He advocated the application of the strongest possible developer. It had been suggested that washing after bleaching might be considerably shortened by immersing the negative in an acid sulphite solution. Such a course, in his opinion, was absolutely harmful. The colour would certainly be discharged, but under certain conditions an insoluble chromium body would be formed, and its presence might afterwards produce stains and streaks. It was much safer to rely on a thorough washing to remove the bichromate.

Mr. Salt said, also on the halation-cure question, that he should prefer to dry the negative prior to its being re-developed. A dry film resisted penetration of a liquid far more than a wet one, though the contrary had frequently been stated. He agreed with Mr. Mees that a strong developer should be employed for the purpose.

The President (Mr. S. H. Wratten) reminded his hearers that, although halation chiefly existed at the base of the film, still much might be done by the old-fashioned remedy of rubbing the film down. As to Mr. Salt's contention, this might be correct; but if the negative was allowed to dry unequally the gelatine would afterwards absorb the developer at a varying rate, which would be undesirable.

Mr. F. W. Hicks, changing the subject somewhat, said he had recently lost a 15 x 12 negative through unequal development. He attributed it to insufficiently mixing his pyro soda developer.

Mr. Mees said this might well be so. Strong soda solutions took a long time to uniformly mix. He had found a vigorous shaking for five or ten minutes in a flask was required. While such a degree of exactitude might not be required in ordinary work, still it pointed to the exercise of greater care in this direction than was usually given.

Patent News.

The following applications for patents were made between November 28 and December 3, 1904:—

Paper.—No. 25,897. "Improvements in and relating to the coating or preparation of paper or other material for photographic purposes." James Harris, Paul Gillard, and Henry Heain Molyneux.

Plate.—No. 26,066. "Self-developing dry plate." William Fraser Cloughton Kelly and John Arthur Bentham.

Papers.—No. 26,247. "An improvement in the manufacture of sensitive photographic printing papers of the class known as self-toning printing out papers." Ernest Charles Morgan.

Microphotography.—No. 26,371. "Improvements in microphotography or photomicrography and apparatus therefor." James Anthony Weale.

Cameras.—No. 26,372. "Improvements in photographic cameras." Friedrich Kalkner.

Last week Mr. B. G. Cooper gave his lecture entitled "Photographic Records," before the Kingston Photographic Society. The lecturer commenced by stating that a branch of the society had been formed with the object of obtaining records in the form of lantern slides, negatives or prints, by any permanent process such as platinumotype, of Surrey subjects either past or present. As an example, some slides were shown of Kingston during the floods of ten years ago, also of the King's Proclamation being read. The National Photographic Record Society had kindly lent some slides for exhibition, and also some very fine prints. There was a very interesting collection of local subjects, Mr. W. M. Robertson having given some very valuable slides. At the close of the meeting, Mr. Cooper asked that anyone who was in possession of any subject of interest would kindly send the same to him.

Commercial & Legal Intelligence

A MAN, giving his name as Alexander Moore, address, 14, St. Kilda Street, Belfast, and occupation, traveller for the American Photo Artist Co., 24, Gresham Street, Belfast, was arrested by Head Constable O'Hara on a charge of having been on the premises of Mr. Ambrose Doherty, grocer and spirit merchant, Irish Street, with intent to commit a felony. The accused was brought before Mr. Henry Newell, J.P., at the police barrack. He was remanded in custody until the petty sessions.

PHOTOGRAPHS for Nothing: Expensive Frames.—James Goldsmith and Co., assignees of Messrs. Wechsler Bros., trading as the United Artistic Company, sued Mary Hannah Plows, wife of Mr. Alfred Plows, auctioneer, Colliergate, York, for 18s. 6d. balance of an account for 45s. price of a picture frame. Wechsler's agents go round the city and offer to enlarge photographs for nothing, and after receiving permission to do so they return with the picture framed and make exorbitant charges for the frame. The plaintiff, in reply to Mr. Plows, said that he had purchased Wechsler's debts and thirty of the debtors were women. Mary Hannah Plows said that she ordered the picture unknown to her husband. A man and woman came to her house and asked her if she would have her photograph enlarged. They said she could have it done for nothing. She consented, and gave them a photograph to enlarge. They subsequently called with samples of framing and asked her to select one for the photograph, and she did so. When they returned with the picture framed they charged 45s. for it. His Honour: Why did you pay all that money for the picture? Mrs. Plows said she did not like to let her husband know. When she had paid 27s. she told her husband, and he told her not to pay any more as she had paid enough. His Honour: I should think so! You agreed to pay 45s. It is a great pity, for if you had told your husband he would have told you it was not worth the money. Mrs. Plows: The same man never came twice. Twenty different ones called for the money. Mr. Plows said that the real value of the framing and glazing of the picture was 2s. 8d., and if the plaintiff's charge was not a complete fraud he did not know what was. The debts were incurred by women without the knowledge of their husbands. His Honour (to plaintiff): You gave £3 for the debts. What was the value of the whole? Plaintiff: £15 or £16. His Honour said Wechsler assigned his debts in that way because he was afraid of being exposed if he came into Court himself. Mr. Plows said the matter had been exposed in the "Yorkshire Herald," and had been cried down in every town in the country. His Honour said it was very foolish for Mrs. Plows to be taken in when her husband was so peculiarly qualified to give an opinion as to the real value of the frame. Mr. Plows said the man never said what the frame was to be until he brought it round with the picture in it. They were going about York now defrauding poor people. His Honour (to plaintiff): I do not think you should mix yourself up in transactions of this sort. It is a fraud, as Mr. Plows has described it. I shall not help you in the matter at all; I do not like it; it is fishy. I should like to have seen Wechsler. I shall give judgment for you, Mrs. Plows, with costs, for I do not believe in tempting poor people and then the man not daring to come into Court. He passes the debt on to some one else for a nominal sum, thinking to escape exposure.

THE public examination of William John Le Couteur, photographer, of 16, Brook Street, Grosvenor Square, S.W., took place at the London Bankruptcy Court on December 9, before Mr. Registrar Brougham. The statement of affairs filed by the debtor disclosed unsecured liabilities amounting to £615 13s. 5d., and assets nil. Replying to questions put by the official receiver, debtor stated that the receiving order was made on the petition of a creditor, the act of bankruptcy being the non-compliance by the debtor with the requirements of a bankruptcy notice duly served upon him. In November, 1899, whilst carrying on business as a photographer, a receiving order was made against him. His liabilities then amounted to £3,915 19s. 10d. No dividend was declared, and he had not obtained his discharge. For some time after that failure he acted as managing director of a company called the Photographic Association, Limited, carrying on business at 16, Brook Street, W., for which he received a salary of £6. per week until June, 1903, when the debenture holders of the company appointed a receiver. He afterwards assisted

his wife in a similar business carried on by her at the same address, but in May last an injunction was obtained against him by the petitioning creditor, who had acquired the business from the company's liquidator, restraining him from being connected with or interested in any photographic business within a certain radius. Since then he had been without occupation and he was dependent upon his friends. He alleged his present position to have been caused through the petitioning creditor's debt for costs incurred in the injunction action. His household furniture was subject to an antenuptial settlement made in September, 1896. Debtor was questioned at some length with regard to a circular sent to the members of the Photographic Association, Limited, in which he said that the association would in future be known as "The Photographic Club," and that unexpired subscriptions would be honoured by the new club. The circular went on to state that "Mr. Le Conteur hopes to do more than he could when embarrassed by the limited company." Debtor explained that when he issued that circular he intended to carry on the business. The lease of the premises and everything was in his wife's name. The association was sometimes called "The Amateur Association," but the latter association was really a branch. The association was in the habit of assisting amateurs of all descriptions, not amateur photographers particularly. He had never heard of the Amateur Association being wound up. The official receiver said the Amateur Association was wound up in the early part of the present year. Debtor said that must have been another amateur association. It came as news to him. Replying to further questions, debtor said the injunction was obtained against him in May last, and he had not done any photographic business since then. He was now living by doing a little business on commission. If it had not been for the adverse judgment in the injunction proceedings he would not have been in his present position, but he still hoped to be able to upset that judgment. The only debt he really owed was one of £10 due to two men who could ill afford to lose their money, and with the leave of the Court he would pay them as soon as he possibly could. The other liabilities were all incurred either in the legal proceedings, or in connection with the company. A creditor wished to question the debtor upon a letter he had received from the official receiver, but the Court would not allow this to be done, on the ground that the debtor could not help what the official receiver had done. The creditor pointed out that the official receiver wrote the letter upon information supplied by the debtor, but the Court declined to allow it to be put in as evidence. Debtor admitted telling the official receiver that the whole of the plant on the premises in Brook Street belonged to his wife. The examination was ordered to be closed.

News and Notes.

"FALLOWFIELD'S COURIER," for December contains some seasonable lines, and also with it is issued a coloured supplement of the Falloroll Camera, which is an excellent piece of colour printing.

THE latest cinematograph film issued by Messrs. Gaumont, of Cecil Court, is one depicting the incidents in the late Wilson Barrett's well-known play, "The Sign of the Cross."

MR. A. H. BAIRD, of Lothian Street and Brighton Street, Edinburgh, has forwarded us a copy of his neatly got up price list of select optical lanterns and accessories for this winter.

WE have received from Robt. W. Paul, 68, High Holborn, W.C., a descriptive circular of the Nernst-Paul optical electric lantern, together with various other projection arc lamps and fittings.

MR. A. W. W. BARTLETT has, we hear, resigned the secretaryship of the Royal Photographic Society, in order to assume the position of advertisement manager to one of the leading photographic firms.

WE have received the 1904 number of the "Christmas Bookseller," which gives one not only a complete list of the books published this fall but, in the majority of cases, a short criticism is included, which gives one an idea of the literary and pictorial merits of the work.

MR. J. C. BURROW, F.R.P.S., of Camberne, the well-known scientific and mining photographer, has been officially informed that the international jury of the St. Louis Exhibition has awarded him a silver medal for his underground mining photographs, sent through the Home Office.

MESSRS. W. WATSON AND SONS, of 313, High Holborn, W.C. request us to announce that their antinous release can now be supplied for the Cadet and Guerry shutters, and can be obtained in lengths up to 15 ft. A small charge is made for adaptation to the shutter.

THE following are the particulars of the Photographic Prize Competition instituted by the "British and Colonial Druggist":—First prize, £3 3s.; second prize, £2 2s.; two prizes of £1 1s. each; and six of 10s. 6d. each. A certificate will accompany each prize. No competitor may send in more than six pictures. Each picture must be, from beginning to end, the work of the competitor. Photographs must be mounted, and each bear on the back the name and address of the competitor, with particulars of the camera, plate, and developer used, and the date on which it was taken. A selection of the pictures sent in will be exhibited at the Chemists' Exhibition at the Royal Opera House, Covent Garden, London, W.C., from March 13 to 17, 1905. The competition is open only to amateurs connected either as principals, assistants, or apprentices with the wholesale or retail branches of pharmacy or allied callings. The photographs must have been taken subsequently to December 31, 1903.

WE beg to call the attention of readers to a letter in our correspondence columns from the well-known trade retoucher, Mr. T. S. Bruce, of Hampstead. We fear we have done an injustice to Mr. Bruce's long-established system of postal instruction in retouching by two replies to correspondents, which we gave in our issue of the 9th inst., headed respectively, "Opinion Wanted," and "Occupation Wanted." Mr. T. S. Bruce has called upon us and proved conclusively, by written testimonials from firms of note and professional retouchers, and employees, that his postal method is undoubtedly effective, and equally so as the personal instruction. It is perfectly clear that both by the postal and the personal lessons, Mr. Bruce is aiding the young professional retoucher to better and quicker finish, in this country and abroad; and also thoroughly initiating the novice, and, therefore, should meet with full and merited appreciation from the profession he benefits. The fact that Mr. T. S. Bruce has been before the photographic public since 1886 speaks for itself and we have every confidence in advising readers who need such instruction to avail themselves of his services.

THE second annual exhibition in connection with the Ilkeston Art, Camera, and Field Club was opened last week by the Mayor (Alfred man R. Hunt). The judges were Mr. C. Barrow Keene, F.R.P.S., and Mr. T. W. Scottton, Derby. Appended is a list of the prize winners:—Members' Classes.—Class A: Landscape, seascape, and river scenery: Silver medal, withheld; bronze medals, F. P. Sudbury and F. Chambers (Stanton); certificates, W. Shakspeare, G. W. Wooliscroft, and A. Wallis (Long Eaton). Class B: Portraiture: figure study, animals, and still life: Silver medal, T. W. Smith; bronze medals, F. R. Lee (Shipley) and W. Shakspeare. Class C: Architecture: Silver medal, Armitage Wallis; bronze medal, G. W. Wooliscroft. Open Classes.—Class D: Picture postcards: Silver medal, withheld; bronze medals, E. Seymour, F. Whitaker, and F. Judge. Class E: Landscape, seascape, and river scenery: Silver medals, C. R. Foxall, T. Wright, and E. J. Jarvis; bronze medal, withheld. Class F: Portraiture, figure study, animals, and still life: Silver medal, T. H. Middleton; bronze medals, E. Seymour and J. W. Barnes. Class G: Architecture: Silver medal, T. Wright; bronze medal, E. H. Atkin.

EXHIBITION at the Wellcome Photographic Club.—Since the firm of Burroughes, Wellcome, and Co. founded a camera club in connection with their institute at Dartford an annual exhibition of members' work has been held there, and the fifth of these was opened on Saturday, December 10, by Mr. R. Clay Sudlow, the manager of the works. Awards in the shape of plaques were this year made to notable exhibitors, and Mr. John H. Gear, who acted as judge, conferred these upon W. H. Powkes ("Shades of Evening"), F. S. Clarke ("The Berelict"), W. Gray ("Birches and Bracken") and H. W. Lane ("Misty Sunrise"). The committee of the club can be congratulated on bringing together a collection of prints which exhibit a good deal of technical merit, and though many of the members, fortunately or unfortunately, are innocent of pictorial aspirations, there are one or two of their number who show promise of doing some very creditable work in this direction. The medallists

photograph of Mr. Fowkes, "Shades of Evening," is a strong piece of work, and, in comparison with another print by another worker, supplies an interesting object-lesson on the power of the photographer to free himself from the limitations of his subject, both negatives having been exposed on practically the same scene and within a few seconds of each other. In addition to the members' work, a number of photographs of Egyptian scenes by Mr. Henry S. Wellcome were displayed.

The Pollak-Virag telegraph is the invention of an Austrian, and a demonstration of it was given in London last week. At the transmitting end the message to be sent is punched out on a typewriter at the rate of 3,000 words an hour, and is reproduced on a perforated tape, which shows a series of small holes in what seems to be bewildering confusion. These holes, however, resolve the writing into its vertical and horizontal components. The perforation can be done at any spot, and the prepared tape sent to the transmitting office. There it is inserted in the aperture of the transmitting instrument, and by the perforations the electrical impulses are created and recorded at the receiving station. From the time the tape leaves the typewriter no further manual operation takes place. In the receiving instrument the impulses created by the two series of perforated components of the writing are received in two telephones, and the vibrations they cause in the diaphragms are communicated to a mirror, which makes vertical or horizontal movements according to the character of the impulse. The combination causes a third motion, by which the reproduction of handwriting is actually obtained. But the writing is so minute that it is almost invisible, and therefore a ray of light is made to fall on the mirror, and is reflected on to a sensitised photographic paper, whereon it traces the message in legible form. The paper passes through a developing and fixing apparatus, and the telegram runs out of the instrument as a broad tape on which the message is clearly photographed. This process is accomplished in ten seconds, and that length of time after the transmission has begun the first part of the message is photographed at the other end, ready for delivery, and continues thereafter running out at the rate of over 40,000 words an hour.

It will be remembered that early in the summer of this year Messrs. W. Butcher and Sons inaugurated a competition for the purpose of making "Coxin," a daylight system of developing, more generally known amongst the photographic community of the country. Twelve illustrations were given, typical of the twelve months of the year, and all the competitors had to do was to decide which month each illustration represented. In addition to the sixty-eight prizes offered to competitors, the firm gave duplicates of the first five prizes to those dealers from whom the successful prize-winners purchased their "Coxin." The following is the list of prize-winners:—First prize, Humber motor bicycle, J. Mason; dealer, Mason, Bradford. Second prize, 25-guinea billiard table, Harry Hadfield; dealer, Hadfield, Milsbridge. Third prize, Monarch gramophone, C. H. Laverack; dealer, Boots, Brighton. Fourth prize, ½-plate outfit, William G. Hodge; dealer, Boots, Hammer-smith. Fifth prize, No. 4 carbine, F. Williamson, jun.; dealer, F. Fallowfield, London. Postcard Cameo Camera: F. R. Harker and G. C. Haigh. Half-plate Photo Outfit: J. Eakin and H. Green. No. 3 Carbine Camera: Herbert Hadfield and H. J. Briant. Postcard Midget Camera: J. G. Hobman and A. E. Smith. No. 0 Midget Camera: H. Minett, O. Seers, J. R. Topp, F. A. Izod, Edith Williams, Annie Whitehouse, E. G. Riches, W. Laxton, R. Pearson, and O. G. Shaw. No. 3 Express Camera: H. Berrill, S. Eastman, J. E. Shillocock, W. Johns, and F. M. Tydeman. No. 2 Express Camera: F. W. Parkin, M. S. Baker, P. H. Fearnley, W. H. Howitt, and H. Froom. No. 1 Express Camera: W. Bridges, jun., F. Lockwood, A. Leak, J. L. Carr, and J. Clark. No. 3 Pilot Camera: E. C. Izod, J. Hadfield, Miss E. A. Cross, E. S. E. Betteley, S. J. Whillans, E. Backhouse, W. Burbridge, W. Baird, W. H. Beaumont, and A. McDonald. The Sketch Camera: Mary A. Finney, W. Gibbins, A. W. Nash, D. W. Neall, W. E. Roberts, May E. Riches, D. T. Richards, S. Thompson, H. A. Collin, R. Milner-White, G. W. Blythe, W. R. Hewlins, M. Hatch, A. B. Haynes, C. Milnes, G. Milligan, A. S. Lewis, G. T. Mathers, W. R. Vickery, and H. B. Adams.

EDINBURGH Photographic Survey Exhibition.—In the presence of a large gathering, the first exhibition of photographs and prints and

drawings of Edinburgh, organised by the Edinburgh Photographic Society, Survey Section, was opened at 38, Castle Street, Edinburgh, last week, by Lord Provost Sir Robert Cranston. Mr. J. Tudor Cundall, B.Sc., chairman of the society, presided, and there were also present, Mr. Geo. McCrae M.P.; Bailie Mitchell and Dobie; Councillors A. A. Murray, McArthy, and Macfarlane; Provost Mackie, Leith, and Mr. Morham, City Architect. The chairman said that this was the first time they had had an exhibition of this character—collecting together photographs and views of old Edinburgh. The idea of such a survey was initiated by their former president, Mr. Eddington, five years ago. Their beautiful city had changed very rapidly, and it was most important that some record of these changes should be preserved. In that respect he hoped that this exhibition would be brought widely before the citizens of Edinburgh. They hoped to collect duplicates of as many pictures as were available. But they had lamentably inaccessible premises, but they hoped for better things. He hoped it was only a beginning of what was to come. He then called upon the Lord Provost to open the exhibition. Sir Robert, who was given a very cordial reception, said he was fully satisfied with the magnificent display. He considered it was his duty to tender to Mr. Eddington the best thanks of the City of Edinburgh for the inauguration of such an exhibition as they had there to-day. The present premises were very inadequate, but he considered that with the goodwill of the Council, they could try to find a room in the Council Chambers which would be suitable for such an important display. Everything that lends to the pleasure of the citizens should be encouraged. Such an exhibition showed what a wonderful development had taken place in the last fifty years. They had laid the foundation of something they could hardly see the end of. The City of Edinburgh never had a Town Council who were willing or more anxious to benefit and do everything for the city than it had at present. They had realised how their duty was to make it as attractive as they possibly could, without waste of money. But money was not wasted that went to beautify the City of Edinburgh. Sir Robert then declared the exhibition open.

LORD REAY distributed the prizes gained by the successful students at the Northampton Institute, Clerkenwell, last week. Mr. L. B. Sebastian, chairman of the governing body, presided, and there was a large attendance of students and their friends. Dr. Walmesley, the principal, said the educational and social work of the institute had shown successful development during the session 1903-4. But the need of increased accommodation was being painfully felt. The establishment of a technical optical section had been amply justified by the results obtained, and it presented an opportunity for the foundation of a "British Institute of Technical Optics" which would tend to bring back to Clerkenwell the position it once held of being the centre and focus of the optical trade of the world. Lord Reay, in the course of an address, congratulated Dr. Walmesley on the success with which the great and important work of the institution had been carried on. The question of apprenticeships was of great importance to the working classes. He had been informed that in London there was no opening for apprentices, and therefore boys who wished to become apprentices had to go into the provinces. A corrective must be found for that condition of things. By the reintroduction of the apprenticeship system the increase of the number of unemployed and of unskilled workmen in London would be prevented. The time had come when the place of the polytechnics in the educational system of London should be clearly defined in order that there should be no overlapping. His views entirely coincided with the development that had been going on in the Northampton Institute, but he did not agree with the development that was going on in some of the other polytechnics. As a result of the passing of the Technical Instruction Acts, the polytechnics came into existence to promote technical education without regard to other kinds of education, but it had been found necessary to have preparatory classes of one kind or another. The time had now come when these polytechnics should do the work for which they had been constituted. They should not be called upon to provide for the continuation of the general education of the students. It was not the work of the polytechnics to give secondary education of any kind that could be obtained elsewhere, and for which the ratepayers were already obliged to pay. It should be the aim of the polytechnics to be the training places of workmen and workwomen, and in this way a well-ordered educational system would be established.

THE ASSOCIATION OF PHOTOGRAPHIC EMPLOYEES.

To the Editors.

Sirs,—The reference in your last issue to an Association for employees is very welcome to those who first moved in this direction in 1890-1, and on their behalf I (as originator of the movement) beg heartily to thank you for your fair and sympathetic attitude. To your remarks let me only add that something more was most decidedly done in the past than merely to "suggest that the thing should be done." See your own esteemed journal for the last weeks of 1889 and first weeks of 1890, your "Almanac" for 1890 and 1891, "Photography" for January 9, 1890, etc. A meeting held January 21, 1891, at the Polytechnic, resolved on the formation of such a society. Work was undertaken by a committee, a branch office or two established in London, one in Edinburgh, etc. In June, 1891, the thing was abandoned solely from lack of members. Only a meagre half-hundred, out of all our thousands, made application, and the bulk of these "broke out in a cold perspiration" when asked to forward subscriptions. Offices, rules, books of account, cards of membership, all were ready, but the photo workers were not.

It is possible we were wrong in giving in, even if only a dozen applicants were willing to join and to pay. It looked very hopeless at the time, however.

Since then an attempt has been made to avail ourselves of a permission to join another society, but recently it has been resolved by that society that only "distributive, not productive," photographers are admissible.

Consequently, within the past few months a number of assistants have been organising a committee to again form an Association of Photographic Employees. When your article appeared we had already pulled into nearly final form all the (of course provisional) rules, forms, etc., for floating the Association. At the outset membership will be solicited on the basis of the provisional rules, which are the quintessence of fifteen years' experience. In several months' time the whole matter will be submitted for confirmation or amendment by a general meeting of members.

Several points are raised by yourself and your correspondents which we would like to answer here, and we wish to point out that the failure of the older proposal was useful in warning us of the pitfalls to avoid:—

1. Would there be a society on strictly trade union lines like labourers' or artisans' union, or would an Association of Employees be formed just as the professional employers have formed one? Reply: A trade union like carpenters' or even like shop assistants' societies has been tried and cannot be made a success; at any rate not at the start. A professional association, like the employers', will be the first form of the attempt. If the members want to register it as a trade union later, they can do so quite easily by resolution of a general meeting. By the Taff Vale decision a young registered trade union is liable to have all its funds swallowed up and confiscated through the least illegality (authorised or unauthorised) committed by any one of its members. Until the law is altered, it will be best to found an unregistered society like the splendid organisation, the Original Society of Paper Makers (hand workers), which embraces 96 per cent. of the calling, and has a reserve of £3 per member in hand, but has never registered. To guard against fraud and embezzlement the entire work will be vested in a good number of substantial trustees, and trustees will be invited from the professional and learned associations of our calling. Within the above limitations the Association will do all the work of a trade union, but will have "Defence, not Defiance" for its motto.

In a word, we hope and believe we shall secure the good will and hearty assistance of the photographic employers. Our attitude will be that employment and labour are a mutual service, and our

aim will be to help to jointly advance the interests of our disorganised and chaotic profession.

2. Would it be a *sine quâ non* that applicants should have served an apprenticeship? Will examinations be held and certificates be granted? Reply: Apprenticeship cannot nowadays be insisted on. Nearly all societies now say: "Apprenticeship or so long a period of employment at the customary rates of wages." So also re examination; we cannot make any entrance examination. With a few customary provisions, the fact of employment in the trade under usual terms for a fair length of time must suffice to admit. But afterwards we will require members to prove by any one of a number of means that they are worthy of being championed and their position advanced. Either qualification by apprenticeship, long employment at high rates of pay, or examination will be required to be proved before the "associate" will advance to "member," and from "member" to a higher grade. The examination referred to may be either (a) a purely practical one by a joint board of our own members and of scientific and commercial examiners, or (b) by production of the P.P.A. new certificates, or (c) by the City and Guilds or Chamber of Commerce certificates, plus a short practical exam., or (d) by the Regent Street Polytechnic certificate.

3. There will be benefits, as well as professional and legal assistance. Members will pay a small sum for only the professional help twice the sum to add unemployed benefit thereto, thrice the sum for a further title to sick pay. Membership above thirty years of age will be graduated, on the usual actuarial rates customary in benefit societies, but this will not affect the purely professional subscription.

4. Scales of salary, hours of labour, half holidays, etc., all come within the scope of the Association, and much can be done by friendly negotiations to secure the recognition of fair terms of employment.

We have secured a very earnest and very experienced organiser of such associations to kindly act as hon. secretary, and he may be addressed as follows:—Mr. Geo. Palmer, Hon. Secretary Assoc. P.E., 20, Bishopsgate Street Without, E.C. What is wanted at the moment is not correspondence requesting us to "send on full particulars and oblige," but promises to help, and criticisms and suggestions for our rules. All correspondence must at this stage contain stamps for reply; and an entrance fee of 1s. will be deducted to any applicant who encloses it, such payment to hold good till he sends a regular subscription.

Fees of this character sent in the initial stage will help to pay the cost of the expensive preliminary work.—Yours faithfully,

London, December 12.

ASSISTANT.

BARNET £500 CASH PRIZES COMPETITION, CLOSING DECEMBER 31.

To the Editors.

Dear Sirs,—To make perfectly clear a point which has been raised by one intending competitor, we beg leave to draw attention to the following:—

General Conditions, 3.—The words "the same print" should be understood to mean "a print from the same negative."

Class 9.—Lantern Slides.—From negatives on Barnet plates films is implied.—Yours truly,

ELLIOTT AND SONS, LTD.

P.S.—May we ask you to kindly call the attention of your readers to the fact that the Barnet Competition absolutely closes on 31st inst. Barnet, Herts, December 7, 1904.

THE BOVRIL COMPETITION.

To the Editors.

Dear Sirs,—In reply to your correspondent's inquiry, a list of successful competitors was published in the "Daily Telegraph" and "Daily Express" of November 21.

All the photographs are being returned to competitors as quick as possible, and a printed list of successes is being enclosed with each parcel. The few photographs not yet returned will be sent off before the 15th inst.

The first two prize-winners were published in the "Illustrated London News" on the 19th ult.

will be readily understood that the large number of photographs involved considerable delay in the adjudication and subsequent repacking of the photos.—We are, dear, sirs, yours faithfully,
BOVRIL, LIMITED.

London, December 9, 1904.

LEARNING RETOUCHING.

To the Editors.

Gentlemen,—Will you kindly permit me to comment upon your answer to "Inquirer," "Occupation Wanted," in the correspondence columns of last week's issue of the *BRITISH JOURNAL OF PHOTOGRAPHY*. "Inquirer" wishes to know if there is a chance of livelihood if he learns retouching, he being well skilled in art and having taken many first-class certificates; but he thinks it cannot be remunerative as he is told three hours must be spent on each negative. To this you reply to the effect that the photographic market is overstocked, and advise him to turn his talents in some other direction, whilst correctly informing him that three hours need not be spent on each negative. A second query of "Inquirer's": "Do you think it possible to gain a knowledge of the method of retouching through postal lessons?" meets with this reply: "Yes, but not so well as by personal instruction." Now, I wish to point out that if any man should learn the art of retouching, surely it would be one to whom it would come easily, as undoubtedly it would "Inquirer," who is already well up in drawing and shading—enough, I may remark, I have had some of my most successful pupils from those who have never had a lesson in drawing in their

life. I am a trade retoucher and teacher of retouching by postal and personal course, and at one time I was in exactly the same position as "Inquirer," and was then told the market was overstocked, and there was no hope for me. That was about twenty years ago, but I learned retouching, and have never regretted it, as I have made much better living at the art than I ever expected or hoped to. My profession and trade is overcrowded, and would be aspirants discouraged wholesale, but I maintain there is room for really workers in every line and direction. If everyone failed to try they were struck down by the bullet of depression and buried in a blanket we should have a world of dead men. Every actor, every artist, etc., cries out "stinking fish" and warns off the new ones, but new blood must come along or it all ends in a standstill. As an employer of retouchers I have found that out of every ten replies to my advertisements that only about five applicants have been really up to the mark. My difficulty was to get first-hands. With regard to "Inquirer's" "three hours . . . spent on each negative," it is absurd!

Forty-five minutes to one hour on an ordinary cab. neg., should be the limit, unless of exceptional difficulty, and this for best finish. The leading firms expect, I believe, about eight cab. negs. a day, and less important firms want a larger number. Finding professional retouchers, especially apprentices—who rarely get much time to devote to retouching, and when they do have no professional teacher to attend to them—so backward, I have made their improvement by quickening a speciality, and with most gratifying results. My pupils have obtained situations with the leading West-end and provincial firms, and many have greatly advanced their market value. Others through having their wives taught retouching, have been able to devote themselves entirely to photography, have formed businesses and become successful photographers. I have changed the occupation of many who were in the same boat as "Inquirer," and to their gain.

There is not a great living to be made at retouching, but, at least, a comfortable one can be secured by any good retoucher, properly equipped, who only displays a little energy and who does not sit in the fence. My brother has been round the world three times, going from place to place as a retoucher, and taking his chance of situations. The market may be overcrowded with weak and derivative retouchers, and I believe it is, and—as with every other branch of work—then all the more reason why they should be improved and not discouraged and turned back.

In your reply that postal lessons are not so good as personal, I may state that I have been teaching by postal course for over

ten years, and have found it equally as effective as the personal instruction, for the pupils are more self-reliant.

I have dozens of high-class testimonials from professional photographers and retouchers all over the world—my latest being from New Zealand, and this pupil was already a good retoucher, but writes that he prefers my methods. If you will refer to the *BRITISH JOURNAL OF PHOTOGRAPHY*, March 15, 1901, under heading "Retouching Lessons by Post" in "Answers to Correspondents" columns, page 176, you will find you then gave my postal system this criticism: "We congratulate both tutor and pupil. The specimens of work sent are very good indeed, and do the greatest credit to Mr. Bruce's method of teaching by post."

I assure you my postal pupils are just as smart as the personal. Finally, I think it would be better for trade all round if every one took a brighter view of things and tried to stir business up rather than depress it with gloomy forebodings.

Several of the halfpenny daily papers have, by their alarmist leaders thrown the country into a chronic state of hump, and closed up hundreds of thousands of pockets that might otherwise have been open as usual. Depression is catching, and the people "follow my leader" like a lot of sheep.—I am, gentlemen, yours faithfully,
Hampstead, December 12.

T. S. BRUCE.

On the 5th inst., at Unity Hall, before the members of the Bowes Park and District Photographic Society, Mr. W. P. Watmough gave a demonstration of "Intensification, Reduction, and Toning," by "tabloid" photographic chemicals. The compact form, ease of manipulation, and reliable keeping qualities of these products appeal conclusively to the amateur photographer, who, with limited dark room accommodation, can by this means have at hand formula for all branches of work, and readily make up the quantity of solution necessary only for the amount of work to be done, and thus ensure having clean and fresh solution each time. Their value to tourists with the camera, owing to their portability, cannot be exaggerated. Mr. Watmough proceeded to tone some lantern slides and bromide papers by means of "tabloid" copper ferrocyanide, when, in place of three ten ounce solutions necessary in the ordinary way, one "tabloid" product to each ounce of water was sufficient. The different tones obtained on both slides and paper by their immersion in the bath for shorter or longer periods was clearly shown, specimens being passed round at different stages of the process. Mr. Watmough pointed out that the developer used in the first instance had some effect in the resultant tone, it being found that Amidol developed prints toned somewhat better than any other. A film was then cut in half and one half intensified by means of mercuric iodide and sodium sulphite, and afterwards developed by means of Amidol, a process always recommended in order to obtain the best results. A comparison was then made with the half not treated to show clearly the increase of density obtained. Another film was treated in the same way, but reduced by means of "tabloid" potassium ferricyanide. The demonstration was followed with great interest by the members, who kept up a fire of questions, to which Mr. Watmough readily replied.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

	s.	d.	
One Year	10	10	France, Belgium, United States, Canada, Australia, Africa, New Zealand, New- foundland, Germany, Russia, Portugal, Spain, Italy, Egypt, India, China, Japan, &c. One Year ...
Half Year	5	5	13s.
Quarter Year	2	9	

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

- W. G. Smith, 162, Oldham Road, Middleton. *Two Photographs of Two Christmas and New Year Post Cards, containing Four Views each, and Greeting.*
- W. Cartmale, Bank House, Lichfield. *Photograph entitled "The King Leaving Lichfield Cathedral." Photograph entitled "Bird's-eye View, Lichfield."*
- H. Dunning, Bridge Street, Usk, Mon. *Photograph of Llangibby Castle House, Monmouthshire.*
- R. Wilkinson, The Studio, Hornsea, Yorks. *Two Photographs of the Rev. C. E. Little.*

PAINTINGS REGISTERED:—

- W. Cartmale, Bank House, Lichfield. *Painting entitled "The Walk, Maple Hayes." Painting entitled "Market Day, Lichfield."*

H. HETHERINGTON.—If you turn to p. xvi of last week's issue you will find the advertisement you require.

S.—We are unable to satisfactorily answer your query without seeing a print showing the faults you complain of.

PROMPTNESS.—We think you have just cause for complaint, for although the weather has been bad, it has hardly warranted such delay.

W. A. DOUGLAS (Albany).—It would be better for you to wait till you arrive here, and then either take private lessons or else seek a situation with a first-class firm.

A SMALL PROFESSIONAL.—It is utterly hopeless to expect Parliament to pass any such Act as you desire. If you deal in apparatus and materials you ought to be able to get dealers' terms.

"PHOTO. ARTIST" asks: "How can I become a member of the R.P.S.?" In reply: On application to the Secretary of the R.P.S., 66, Russell Square, W.C., a form can be obtained which, when filled up, is submitted to council, and election will follow, as a rule, in due course.

H. COLLEY BRIERLEY asks: "Can you tell me the cause of films coming out positive instead of negative? Some films used on a voyage to India and developed out there have done so, and as some of them are otherwise very good I shall be much obliged if you can tell me how to remedy them, if possible. Is it any fault in the manufacture?" In reply: This phenomenon is known as reversal of the image, and is generally due either to extreme under exposure, prolonged development, or excessive over-exposure. It is in no way due to the manufacture of the films. The only remedy is to make a negative by copying in the camera or contact.

SENSITISING FILMS.—"ERYTHROSINE" writes: "I invoke your help to advise me in extending my knowledge of sensitising gelatine emulsion for the different colours. If plates are used no trouble is experienced, but with films there is no certainty of results. The only cause of failure that occurs to me is in the free alkali used. Even with erythrosine (Hochst), no good result is obtained. Do you think the ammonia may affect the celluloid so that fog producing actions are set up in the emulsion?" In reply: We certainly cannot accept the suggestion that ammonia

would have any action on the celluloid and set up a foggy action. The difference in behaviour between films and plates is far more likely due to difference in the composition of the emulsion. As colour-sensitive films can now be obtained at the same price as ordinary, we fail to see what the particular advantage in home sensitising is.

"AN ANXIOUS ONE" writes: "Being a constant reader of the B. J. I should be obliged if you would kindly enlighten me on the point: Myself and a friend went out taking views together. We took two negatives of one particular view, my friend taking one negative; I kept the other. Now I have had an offer from a firm to sell a print to them for reproduction one process only. What I want to know is this: If I sell to the firm a print giving them the rights of reproduction, would that affect my friend, or myself, should my friend at any time have an offer or wish to sell a print from his negative for reproduction? He is in his own business and I am in my own." In reply: Two or two million people may take the same view from the same standpoint at the same or different times, and each has a perfect right to dispose of a print for reproduction without legally or morally damaging the other and without prejudicing himself if the other at any future time sells the print or otherwise disposes of the negative.

"STANFIELD" writes: "I placed an order for local view postcards with a firm of publishers and printers of postcards verbally through the medium of their London representative. The views were to be my selection, and their photographer was requested by me to meet me at a specified date and place and take same, the set of views to be my series, which you will see by enclosed card is marked 'London Bazaar Series.' At the time of ordering I produced an estimate from a Continental firm, showing a great difference in price of printing (from own negatives), remarking to the agent that I could get a series of fourteen local views at 2s. 6d. each, showing him that with the 2s. 6d. extra added to the Continental firm's price was a long way under his price, adding that to get my own views, and quickly (as he added), I would not mind paying extra price; also that he would not do the next edition unless he could come down to the Continental price. An important point, I think, showing that he fully understood they were copyright, is the following circumstance, viz., the firm sent about five views, with the wording 'London Bazaar' omitted, and I told the agent I would return them unless an allowance was made; this at first they refused to do, saying they would take them back and reprint. I pointed out to him that would be a dead loss to them, as I should not allow them to sell them at their retail shops, or wholesale in their general conditions, as they were my copyright. Eventually they made allowance. Why did they make the allowance if they were not convinced they had no right to dispose of them? I have since had an edition printed abroad from these same sil prints, and they now write saying I am infringing their copyrights, and intend issuing an injunction. I contend they own my copyrights; that they took the views by my order; that they have no right to reprint them other than for me. What is your opinion?" In reply: We think in a case of this sort verbal agreements are a great mistake, the necessary time and trouble involved in putting the facts into writing are small that in view of future business, and the ease with which such must go through when everything is set down in black and white, this is warranted. The local views were taken at the instance of our correspondent, not by him; apparently he has paid nothing for the making of the negatives, and they were never in his possession, and were simply to be used and for his series of postcards. The copyright belongs to the firm who made the negatives. The fact that a second edition was to be produced at a lower rate seems to us to be utterly beside the question of copyright. Again, the allowance made by the firm to avoid reprinting. We consider that the firm in question hold the copyright, or can hold it if required, and that our correspondent, having put himself in the clutches by having the cards reproduced elsewhere, had better make the best terms he can.

EX CATHEDRA.

Lunar Photography. Thanks to the great telescopes and the photographic plate, we know the surface of the moon—the one which it presents to us—better than we know our own planet. There are no dark lunar continents. Perhaps the finest example among photographic maps of the moon is Professor W. H. Pickering's new work, "The Moon," just issued by John Murray. The lunar craters are depicted with a fulness of detail which was impossible in the days of the draughtsman, and is one more testimony to the value of the camera to the astronomer.

* * *

Ah Sin and Art. Every one who has any love for art must feel regret when some masterpiece in sculpture or painting is borne away by an American millionaire to the other side of the Atlantic. But it comes as a surprise to find the same sentiment expressed by a Chinaman who writes to the "Chronicle" from Hong Kong to this effect. He has a suggestion to make which is a further sign of his Western knowledge. Why, he asks, is not more done in the way of photographically reproducing the contents of European galleries? Possibly he is not aware of the extent to which reproductions are issued; but the fact that such a protest should issue at all from the Far East is a sufficiently surprising fact.

* * *

Photographs on Visiting Cards. Acute distress of mind is professed by the "Daily Chronicle" at the suggestion that visiting cards should be illustrative. Mr. John Smith will be seen in person on his card, and Madame's, perhaps, will be embellished with the picture of

her favourite poodle. Was it not Mr. Barry Pain's "Eliza's Husband" who favoured the idea of a neatly-decorated card—a conventional flower in the top left-hand corner—but was deterred from it from apprehension of an increase in the normal price of a shilling for fifty? There is really no cause for alarm. Probably no one is sufficiently fond of his own features to leave them in miniature on the card trays of his friends. The mind of a town traveller may see novelty in the idea, though many of his predecessors have adopted it. Because of this very opportunity of self-advertisement the "Globe" shrinks from the proposal, foreseeing the card of the newest trade millionaire, no longer decorously bald, but drawn up in such terms as: "What's the matter with Blank's pickles? Adults love them. Children cry for them. Buy them."

* * *

Impure Washing Soda.

It is not so very long ago that a case of adulterated washing soda cropped up, and this week two grocers and oilmen were fined for selling washing soda containing Glauber's salt (sulphate of soda). It was argued for the defendants that the material was sold as soda crystals, and that that term did not imply washing soda only, but was used to describe many forms of crystallised soda. But while various fancy names may be given to washing soda in a retail way, "soda crystals" in the alkali trade means crystallised carbonate of soda, free from caustic alkali, and certainly containing no more than minute quantities of sulphate of soda. The sophistication of a substance so largely employed in photography should not be disregarded, for the effect of sulphate of soda will be felt, not only in the feebleness of alkalinity of the carbonate, but in the restraining action which the sulphate exerts in development. If there is any doubt of the purity of a supply of washing soda the pure crystallised carbonate of soda should be used, and, indeed, those who purchase chemicals on the small scale for their own use only will be well advised to employ it invariably.

* * *

New Names for Metric Measures.

Those who have been reared in the metric system will have to become accustomed to some new terms in its nomenclature if the suggestions of the "Pharmacopœia Committee of the Pharmaceutical Society are adopted by the Board of Trade. By the Weights and Measures Act of 1897 the cubic centimetre, which is not precisely the one-thousandth part of the litre, ceased to be a legal measure of capacity. In place of it the "millilitre" was adopted officially, being defined as the exact thousandth part of one litre. The difference in actual work is too small to be of the slightest importance, so far as everyday photography is concerned. In fact, the processes of volumetric analysis which would be vitiated in accuracy by the employment of c.c.s. instead of millilitres.

are very few indeed. But millilitre is never likely to come into popular usage, and it is now proposed to abbreviate it to "mil." The tenth part of a millilitre is to be called a "decimil" and the hundredth part one "centimil." No doubt, while the handwriting of physicians so frequently leaves room for the scientific use of the imagination, such safeguards against errors are most desirable, but for practical purposes, either of chemistry or photography, there is little to be gained by getting rid of the cubic centimetre.

* * *

An Emulsion Patent.

Great sensitiveness and fine grain are claimed for a process of emulsion preparation, for which protection has been granted in Germany. The description given by the patentee, Herr J. Gaedicke, shows that the process is certainly roundabout, sufficiently so to be uncommercial, we should think; but it does not convince us that there is any actual novelty or advance. In brief, the method is said to consist in the preparation of a slow, unripened emulsion, which is afterwards rendered sensitive by ammonia or other alkali, the alkali being finally neutralised with an acid. It is stated that the emulsion is allowed to set at once and forthwith pressed through canvas and washed. It is then liquefied, with possibly the addition of gelatine, and diluted to twenty times the weight of the dissolved gelatine. It is then warmed to 165 deg. Fahr. and a few cubic centimetres of ammonia or trimethylamine added. The whole is digested at 105 deg. for from one to four hours, and the alkali then neutralised by the addition of tartaric, citric, oxalic, or sulphuric acid. The emulsion is then ready to be used. Photographic literature of the eighties contains many such prescriptions for the preparation of a more rapid emulsion, though it was usual to remove the ammonia by washing. It is difficult to see how any benefit is expected from citrate or sulphate of ammonia in the film.

* * *

Supplementary Exposure.

For some years it was one of the articles of faith of the old worker that a supplementary exposure enabled better results to be obtained, particularly in cases of under-exposure. Many devices were arranged by means of which the supplemental or flash exposure, as it was sometimes called, could be made, and both white and red light were used for this purpose. A patent has been recently taken out in Germany with the same intent, for the placing behind a sensitive plate or film in the dark-slide of a phosphorescent surface, and allowing the two to remain in situ for from twelve to twenty-four hours. The patentee states that during exposure the rays that produce the latent image partially penetrate the plate or film, and produce a faintly phosphorescent image, which by continued contact with the plate produces a better exposed image, and considerably softer images, whilst increased orthochromatic action is obtained, so that yellow, green, orange, and red appear proportionately much stronger in the negative, and blue and violet much softer than when the light-absorbing and light-emitting screen is omitted. This action, it is stated, is much stronger if the dark slide be warmed for a few minutes after exposure. Some four years ago, Captain Colson suggested that a better exposed result was obtained if the plate was exposed through the glass and the film was backed up by a piece of white card or other reflecting material. In this case, of course, the film was practically in contact with the reflecting surface. What the precise result would be when a comparatively thick glass support is interposed between the phosphorescent surface and the light sensitive film remains to be proved. At first sight, at any rate, it hardly suggests fine definition; nor is it

possible to quite accept the statement that a better orthochromatic rendering is to be obtained.

* * *

Honours to English Men of Science.

At the anniversary meeting of the Chemical Society, the Copley Medal was presented by the President to Sir William Crookes "for his experimental researches in chemistry extending over a period of fifty years." Photography may be proud of such a man, who early graduated in photographic work, and who, it may be remembered, in the early days of this Journal, occupied its editorial chair. Then, again, at one time, when wet-plate photography was virtually the only photographic process in use, the names of Mawson and Swan were as familiar as household words. Mr. Swan is now Sir J. W. Swan, whose name is known all over the world, and on the same occasion he was presented with the Hughes Medal, awarded to him "for his invention of the incandescent electric lamp and his other inventions and improvements in the practical applications of electricity. Not directly included in the award are his inventions in dry-plate photography, which have so much increased our powers of experimental investigation." Though not directly connected with photographic work among the week's announcements of awards may be noted that the first occasion of the Lavoisier Gold Medal being awarded to a British man of science is the receipt by Professor Sir James Dewar, F.R.S., for his researches on the liquefaction of gases. To complete the tale the distribution of the Nobel prizes is announced, Sir William Ramsay having been awarded the £8,000 prize for chemistry research, and Lord Rayleigh, Professor of Natural Philosophy at the Royal Institute, that for physics.

* * *

The First American Photographic Salon.

Judging from the reports in our American contemporaries, this exhibition has been a decided success, numerically, at any rate, notwithstanding the rabid opinion it has met with in certain quarters, for no less than 9,000 prints were entered of which 2,000 passed an ordinary jury, and this number was still further reduced to 350 by the jury of artists. The "Photo-Era" says:—"The work of the jury upset many of the preconceived ideas of the Salon Committee. Many prints which a jury of photographers had passed in previous instances were rejected as unsound, and some work lacking in some technical points was declared to be artistically good. The majority of the gum-bichromate prints submitted were rejected, and those accepted were almost wholly straight work. The mixture of hand work and lens work was almost always disastrous. Photographs were judged as such, and examples of brush work were judged as paintings. One of the jurors said on this point: 'Some of this brush work must be regarded as painting, and much of it is better than a poor painter could do; but when photographers place their work on the level of painting, it must be judged as painting, and be as good as the work of a good painter.' The most important point with the jury was the truth of the values. Every picture in which values were not correctly and harmoniously rendered was rejected. This was an innovation, for previous salon juries have considered mainly the question of tone. While tone is one of the fundamentals of art, line is far more important, and value supreme, and both of these essentials have been much neglected in the past by photographers. Now that a new standard of judgment has been set up by a wholly competent jury, we may expect to see definite progress towards photographic truth."

Grave
Error
in Star
Photographs.

Professor Turner, in last week's "Nature" discusses a very disturbing matter which has lately been noted in regard to photographic star records in the Circular No. 11 of the International Astrophotographic Conference of July, 1900. If there is one class of evidence more than another held as supplying irrefragable data it is the negatives taken of the stars and planets, when subjected to certain well-known corrections; but in measuring the photographs of the planet Eros, taken in the winter of 1900-1, when it made a very near approach to this earth, a serious discrepancy has been observed between the photographs taken in Paris and those in Algiers, with instruments as precisely similar as the constructor could make them, although the plates were used the same way, and measured similarly, with careful attention to certain known sources of error. It may be said that it is rather late in the day to make this discovery—four years belated—but, as Professor Turner points out, the measurement of the plates involves enormous labour, and has only been partially accomplished even yet. This error may be briefly described as a variation in the relative positions of the stars on the negatives taken, instead of their being in one constant position. The actual difference may appear but slight, yet, when it refers to objects at such immense distances, it means entire absence of the exactitude anticipated and expected. The error is not the same in all, but it ranges over half a second of arc, and, as Professor Turner writes, "We want to measure the hundredth of a second." The extraordinary delicacy of measurement involved will be seen if we reckon this up into ordinary figures. The focus of the telescopes used is not given; but let us assume it to be twelve feet. Half a second of arc variation then would mean about the three-thousandth of an inch—that is to say, taking a concrete example, a star on one plate does not coincide with its position on another by a distance equal to the thickness of a page in the "B.J.P. Almanac" split into six! "It is disappointing," he says, "to find no satisfactory suggestion as to the cause of error in the paper which gives an account of it." Professor Turner goes on to say: "It seems more likely to the writer that the cause may be sought in the object-glass of the photographic telescope, and, to be more precise, in an error of centring of the crown lens relatively to the flint. Such an error is well known to opticians, and is easily detected in the visual telescope by the fringe of colour on one side of a star image, when slightly out of focus. But the images formed by a photographic telescope are not examined by the eye in the regular course of work, and such an error might therefore escape detection until revealed by such a comparison of measures as is given above. The stray light on one side of the image would not be strong enough to affect the sensitive film in the case of faint stars, but for a bright star it would spread the image in that direction, and so introduce a spurious displacement of the centre. If this explanation be correct, the error can both be detected and eliminated by turning the object-glass through 180 deg." The whole matter is so important, and, we might say, unanticipated, that we may expect to see it well discussed, and probably to the benefit of our optical knowledge; we do not anticipate that it will in any way prove that the photographic aspect of the question will need reviewing.

THE CARBON PROCESS FOR PICTURES IN
VARIOUS COLOURS.

At the present time there seems to be an increasing desire amongst photographers and their patrons for pictures in a variety of colours, such as various shades of reds, browns, blues, greens, etc., and the demand has to be met. A very general method of meeting it is by toning bromide pictures in various ways, but it must be admitted that it is a somewhat troublesome one, especially when several different solutions have to be employed. The "boiling" method for browns or sepias is perhaps the least troublesome, and the colours obtainable with it are good. It is, however, when we come to some of the other colours, such as blues, greens, reds, by toning, that the trouble steps in, with all but those who take extra pleasure in photographic manipulation. There is also the doubt—and a serious one it is with some of the methods—as to the stability of the results when they are obtained. Furthermore, it is a difficult matter, with all but the most experienced, to obtain, with some colours, say, half a dozen or a dozen prints all of the same identical tint. This may not be a serious matter with the amateur, but with the professional the case is different. His pictures must all be of the colour ordered by his customer.

The process that yields the greatest variety of colours with certainty is, undoubtedly, the carbon process, and with it there is no question of getting the prints of exactly the same colour, while of their stability there is no question. All manufacturers of the tissues are now issuing some twenty or more different colours, and the tints of these vary with the different makers, although they may bear similar names. Therefore, he who cannot get a colour or tint to suit his taste must indeed be difficult to please. The carbon process is one of the simplest of all to work, yet there seems to be two objections to it.

The first objection is that if the tissue be purchased ready sensitised, a dozen pieces must be taken at a time, when often only half a dozen, or less, prints are required, and, as the tissue will only keep for a couple of weeks or so, the rest is wasted, unless it be stored in a chloride of calcium case, and that is not possessed by every one. Still, if some of the dozen pieces have to be wasted, the loss is not, after all, very great; yet one does not like wasting material. The second objection is this: If the tissue has to be sensitised by the user, the idea seems to prevail that it is a troublesome business unless suitable drying arrangements are at command. To dispel this idea is the object of the present article.

In all the text-books great stress is laid on the conditions under which the tissue, after sensitising, must be dried in order to avoid partial or complete insolubility and other troubles. These are such as avoidance of noxious vapours from drains, fumes from burning gas, dust, etc.; also that the tissue must not be dried too slowly. It is true that all these precautions have to be taken when the tissue is dealt with in large quantities—as in its manufacture—or when large sheets are concerned. When, however, small pieces—say up to 12 by 10, or even larger—are required there is no difficulty in the way if the following method be adopted. With it the tissue may be sensitised and dried in any ordinary room in full daylight, while at the same time it will be protected from injurious fumes even if gas be burning in the place, while injury from dust is avoided. The method is not new, as it has before been referred to in the JOURNAL, but it does not appear to be so generally known to small workers of the carbon process as it deserves to be. If it were, it would doubtless be the one most generally

Borough Polytechnic Photographic Society.—The tenth annual exhibition of this society will be opened on Tuesday, December 27, at 7 p.m., by the Mayor of Southwark (the Rev. A. W. Jephson, M.A., L.C.C.), and will close on Saturday, December 31. Admission free.

employed by those desirous of producing pictures either on paper or as lantern slides in a variety of colours.

Here is the method. First the sensitising bath is made. A convenient strength is two ounces of bichromate of potash in three pints of water. When dissolved, a dram or two of liquor ammonia is added. The quantity of ammonia is very immaterial, so long as it is sufficient to neutralise any free acid that may be in the bichromate, as any excess flies off as the tissue dries. The solution may be used over and over again, or until it becomes a pronounced brown in colour. Various additions to the bichromate solution have at times been suggested, but they are quite unnecessary, and are not used by practical workers, or by makers of tissues. There is a decided advantage in sensitising one's own tissue that may be pointed out here, namely, that it may be sensitised to specially suit different types of negatives, and that with the same solution. It is tolerably well known nowadays, in the carbon process, that a negative which has harsh contrasts should be printed in a strongly sensitised tissue, and one lacking in contrasts in a weakly sensitised one, in order to get the best results the negative is capable of yielding.

The tissue is immersed in the solution—adhering air bubbles, of course, being removed—and allowed to remain according to the degree of sensitiveness desired. A long immersion means a highly sensitised tissue, by reason of the quantity of solution absorbed by the gelatinous coating. A short immersion, on the other hand, produces a less sensitive one, suitable for flat or feeble negatives. As a rough guide to time, it may be mentioned that for a medium type of negative, if the tissue be allowed to remain in the bath until it just becomes flaccid, it will be about right. When the tissue has absorbed the requisite quantity of solution (large or small), it is removed and squeezed on to a ferrotype plate, or one of tin, zinc, or the like, which has previously been rubbed over with French chalk or been very slightly waxed, and then reared up in some place, where it will dry in a few hours—say on a mantel-shelf with the tissue next the wall. When dry, it can be stripped off the plate, and is then ready for use; it will be perfectly flat, and will possess the surface of the plate upon which it was dried. Now, it will be seen that, while drying, the gelatinous surface will be perfectly protected from all injurious fumes, and also from dust, while the paper, yellowed by the bichromate, will be ample protection from light, whether day or artificial.

A word should be said about the squeegeeing. If a highly sensitised tissue be desired, this should be lightly done, only sufficiently heavy to just remove, or rather equalise, the superfluous solution. If a very lightly sensitised one is wished, the squeegeeing may be done heavily, so as to remove as much as possible of the solution, even from the paper backing. It will now be seen that the sensitising and drying of carbon tissue in small quantities is an exceedingly simple and certain operation, while the working of the carbon process, as most know, is simplicity itself.

THE first Bohemian concert of the "Gramme" Recreation Club, which has been founded by the employees of Messrs. J. J. Griffin and Sons, Ltd., was held on Saturday last at the Holborn Restaurant, Mr. T. Briggs (director) in the chair, and he was supported by Messrs. Pennell, Cornute, Thompson, and Shepherd. A most enjoyable evening was spent, and the efforts of the following artists were particularly appreciated:—Miss Pesenti, Mrs. Reid, and Messrs. Wilson, Wiles, Read, and Williams. So successful were the whole arrangements that it is hoped to give further concerts from time to time.

SODA.

THE case of adulteration to which we refer under "E. Cathedra" is a reminder of the confusion which would seem to exist in the minds of many photographers as to the different substances, which are loosely called "soda" in the wholesale or retail trade. Caustic soda, washing soda or sodium bicarbonate might each be supplied to a person who asks for "soda": which he would get depends on the status of the salesman. Now, in photographic work the most commonly used sodium alkali is sodium carbonate in the crystalline form, the "soda crystals" of the Tunbridge Wells case. Usually it is specified as "soda carbonate, cryst." in formulae, but if the crystallised form is not specified it is safe to assume that the crystals are meant. Dry, or anhydrous, sodium carbonate, which is the only other form of carbonate in the retail trade, is not likely to be meant by a writer unless he specially directs its use. It is the strongest form of sodium carbonate to be obtained, and, roughly speaking, will do the work of three times its weight of the crystallised salt. This latter, sold as "soda carb. cryst.," "soda crystals"—washing soda—should contain, if pure, 37.07 per cent. of the dry sodium carbonate. Bottled samples, supplied to photographers, which we have examined, have contained a little in excess of that proportion—a fact which naturally comes about from the efflorescent property of the salt. Commercial washing sodas are not so pure as this. We have found them to contain 34 per cent. of dry carbonate, which is a little less than the standard quoted by the analysts called for the prosecution in the Tunbridge case. So long as they are within a per cent. or two of this figure, however, there should be no reason to complain of the carbonate in development and for other photographic purposes. But it will be different if a sample so impure as those taken at Tunbridge is being used. The percentages of sulphate of soda found by the analysts were:—

34 p.c.	18.78 p.c.	61.87 p.c.	60.7 p.c.
---------	------------	------------	-----------

The differences in these figures are explained by the supposition that the sulphate had been added to the carbonate after the manufacture of the latter. The percentages of crystallised carbonate were:—

64 p.c.	78.89 p.c.	35.29 p.c.	39.2 p.c.
---------	------------	------------	-----------

which figures must be divided by three, roughly, to obtain the percentage of actual dry sodium carbonate.

The moral of these figures is that apparent vagaries in development may be capable of explanation on examination of the chemicals, and, though that course is not usually the one which the photographer is in a position to take, the moral is no less pertinent when it takes the form of advice to purchase reputable brands from reliable sources, and to recollect that a trifle saved in chemicals may work out to the spoiling of the ship for the proverbial ha'porth of tar.

LORD WILLIAM NEVILL appeared recently at the Tunbridge Wells County Court upon a judgment summons in respect of a debt of £20 for photographs, due to a local photographer named Glanville. On behalf of the judgment creditor, it was stated that the debt was originally about £70, and it was in respect of photographs of Lord William and his family and of some graves. Lord William Nevill told Judge Emden that he was entirely without means, and, although he lived in Eaton Square, he was dependent upon his friends for everything. The sale of his book produced about £400, most of which was distributed among his creditors. His debts at the present time were over £3,000, and he had no means of paying them. The Judge held that there was not sufficient evidence of means, and he made no order. He remitted the fine of £5 imposed upon the debtor for not appearing at the last Court.

THE STEREOFACITOR.

A NEW ATTACHMENT FOR THE STEREOSCOPE.

UNDOUBTEDLY nothing photographic is more beautiful than a well-executed stereogram as seen in the stereoscope, especially a stereoscopic transparency. It is not every photographer, however, who possesses the means of obtaining stereoscopic negatives, in spite of the various easy methods of working with one lens only, or who, having the means, can always spare the necessary time, or rely on his apparatus being at hand exactly when opportunity favours. There are sure to be many excellent pictures which the worker, perhaps, regretfully wishes he had taken stereoscopically, in order to receive the full advantage of the admirable relief which is evidently there present, though thrown away, in the monocular photograph. To such the following description of a very simple method by which a pair of ordinary non-stereoscopic prints or transparencies may be viewed in remarkably realistic relief may possibly appeal, besides proving attractive also to the more serious body of stereoscopic workers.

It goes without saying that actual stereoscopic relief cannot

Fig. 1

be obtained by the use of two similar pictures. Far be it from the writer to resuscitate this ancient and exploded heresy, which, however, appears in its time to have misled many. The method of using the two similar prints now to be described is such that, while under examination in the special holder provided for the purpose, they virtually cease to be similar prints, becoming in reality a pair of dissimilar pictures. This may sound paradoxical, but is, as will now be shown, not only possible, but easily accomplished.

Suppose, for example, we take the case of a couple of squares divided with a number of equally spaced vertical lines, as in Fig. 1. When a couple of these similarly divided squares are placed with their centres in line with the axes of the eyes, the rays proceeding from the different lines of each diagram will be absolutely identical. If, however, these two diagrams are inclined equally so that their outside edges are nearer to the observer than the point of junction, as shown in plan by Fig. 2, the rays reaching the eyes are no longer at equal distances apart, as will be readily seen. The rays proceeding from the division lines on the squares are, in fact, further apart on the left-hand side of the diagram A and

closer together on the right-hand; while in the diagram B this condition of affairs is exactly reversed. In other words, when viewed in the manner described, a pair of similar pictures have become dissimilar.

Of course, it is not suggested that even two dissimilar pictures will necessarily give a stereoscopic effect unless certain other conditions are fulfilled. Nor will the inclination of two similar pictures in the manner described reproduce the state of things obtaining in a pair of ordinary stereoscopic prints. It will, however, go very far towards this consummation, especially when the artificial dissimilarity is assisted by a simple expedient in mounting. Two exactly similar prints are obtained and trimmed to a suitable size, say about $3\frac{1}{2}$ in. by 3 in., taking care that all horizontal parts of the pictures are level with each other. The two prints must be cut to precisely the same size and include an identical amount of subject. Next carefully rule with a pencil and trim off one-eighth of an inch from the right-hand side of the right picture and a similar amount from the left-hand side of the left picture, as shown by the dotted lines in Fig. 3. Then mount the two prints in the same relative position, at about one-eighth of an inch apart, seeing that they are perfectly level. Thin cardboard should be used

Fig. 2.

for the purpose. When the prints are dry any necessary spotting or burnishing may be done, and a line is now scored lightly with a penknife down the centre of the card between the pictures, so that it will readily fold in the middle. The cardboard should not be cut right through, and, in any case, a hinge of gummed paper or thin tape at the back will be an improvement.

The slide is now ready for viewing, for which a special holder is required. To this the writer and inventor has given the name of the "Stereofactor," as fairly well expressing its peculiar function and use. It consists of a pair of metal grooves inclined to each other at an angle of about 140 degrees, with, in the centre, a pair of upright springs forming a clip to hold the slide. This device is readily fashioned in thin brass, aluminium, zinc, or tin by any one handy with tools, or will be made to order by any metal worker for a small charge. It can be screwed to the slide holder of the stereoscope, but it might equally well be provided with spring clips at the bottom to grip any holder; and, indeed, this would be necessary if the instrument used were one of the aluminium construction now popular.

In use, the slide is bent in the middle and inserted between

the springs of the upright clip, the bottom of the slide resting in the grooves below. The slides should be examined in a bright light, falling equally on both pictures, and with the holder as far removed from the eyepiece as it is possible for the observer to see comfortably in sharp focus. A single picture will then be perceived, possessing remarkable relief and realism. So much is this the case that many to whom the effect has been shown have been unable to distinguish between the relief produced by this means and that resulting from the display of actual stereoscopic slides. It should be noted that the use of the holder for viewing the latter is in no way interfered with, but that the two descriptions of slides may be viewed alternately without any alteration of the instrument, except that the focus will differ slightly in each case, which is easily allowed for in the modern pattern of stereoscope.

It may be stated at once that every subject is not suitable for this method of inspection. Since the sensation of relief obtained is not secured by the ordinary means of stereoscopy, but is largely suggestive and imaginative, it is requisite that relief should be as fully as possible rendered in the picture. That is to say, the prints selected must be bright, vigorous, and well modelled, with the divers planes properly differentiated. Unless this condition is secured the result will be disappointing. The sensation of relief is apparently,

Fig. 3.

to a great extent, caused by a favourable conjunction of what are known as the criteria of distance, which seem to receive an added emphasis by the combined use of the stereoscopic lenses and the stereofactor attachment. That a certain kind and degree of relief, varying according to the suitability of the subject, may be perceived under favourable circumstances even in a single photograph, the well-known "Verant" of Dr. Moritz von Rohr amply proves.

A great merit of the stereofactor attachment is the variety of material which may be pressed into service as slides. Picture postcards, both plain and coloured, ordinary portraits, advertisements and engravings cut from the illustrated journals, may be suitably trimmed, mounted, and adapted for viewing. Duplicate pairs of transparencies or lantern slides are also available, and afford striking pictures. The mounting, once understood, is amazingly simple, and dozens of excellent slides may be made in an evening. The interest of the stereoscope is, needless to say, immensely enhanced, and its scope greatly widened. There soon comes a peculiar fascination in watching for suitable subjects and promptly making or obtaining an extra copy.

Of course, the stereofactor picture can never expect to supersede the legitimate stereoscopic slide. Such a thing is not for a moment desired or suggested. It is merely intended to occupy its distinctive place as a useful accessory to the stereoscope, enabling many previously impossible sub-

jects to be included in the worker's harvest of slides. We have used the word distinctive advisedly; for while in many cases the rendering of relief by the stereofactor is not inferior to that of ordinary stereoscopy, in some instances it is distinctly superior. This is, after all, only what might be expected, considering the totally different principle on which the two systems proceed. Curiously enough, the apprehension of relief as shown by a stereofactor picture, being so much a matter of suggestion, appears to vary in different individuals, although in the majority of cases the effect is at once recognised and appreciated, in one or two instances the observer has professed utter inability to see any relief whatever. The same thing has, however, in a somewhat different form, been said of the ordinary stereoscopic slide. It would seem that there are some people whose power of visual accommodation, psychical perception, or whatever it may be preferred to call it, is less developed than that of others.

A. LOCKETT.

ON THE DEVELOPING PROPERTIES OF PURE SODIUM HYDROSULPHITE AND OF SOME ORGANIC HYDROSULPHITES.

ALKALINE Hydrosulphites.—The developing properties of hydrosulphurous acid and of alkaline hydrosulphites were shown for the first time in the year 1887⁽¹⁾. In order to use these substances as developers, they must be produced in the dish at the moment of developing, owing to their unstable nature as they speedily lose their developing power.

Hydrosulphurous acid was originally formed by the addition of granulated zinc to a solution of sulphurous acid. In addition to the hydrosulphurous acid, the liquid contained hydrosulphite of zinc. The images produced were weak and fogged.

Hydrosulphite of soda, prepared by adding granulated zinc to bisulphite of soda, gives results which are inferior even to those supplied by the solution of nascent hydrosulphurous acid⁽²⁾.

No practical improvement having been made in the stability and purification of hydrosulphurous acid or of its salts since its developing properties were indicated, the results obtained by development with that substance have not improved.

Quite recently the Badische Anilin und Soda Fabrik has succeeded in obtaining pure anhydrous hydrosulphite of soda by treating with sulphurous anhydride sodium suspended in ether⁽²⁾. The resulting product has the appearance of a white powder, is unalterable in dry air, is readily soluble in water, while its aqueous solutions only decompose slowly.

Our study of the developing properties of this substance has proved them to be widely different from those of the impure product formerly experimented with.

The aqueous solution of pure sodium hydrosulphite acts as an energetic developer, the image obtained being very vigorous, but fog forms within a few seconds, and increases as development is prolonged.

It is possible, however, completely to avoid this fogging by the addition of a sufficient quantity of 10 per cent. solution of potassium bromide to the developer, and the use of hydrosulphite solutions suitably diluted and sufficiently acidulated by sodium bisulphite. The following proportions appeared to us to give the best results:—

Water	1,000 cc.
Hydrosulphite of soda	20 cc.
10 per cent. solution potassium bromide	70 cc.
Commercial bisulphite of soda	100 cc.

With this developer a normal exposure may be developed.

¹ A. & L. Lumière, "Bulletin de la Société Française de Photographie," 1887.

² French Patent No. 336,942.

in about three minutes. An excess of sodium bisulphite does not appreciably prolong development.

If the hydrosulphurous acid is freed by adding an acid to the hydrosulphite solution, it becomes brown, and loses considerably in developing power, the image being less vigorous and considerably more fogged than with the hydrosulphite of soda.

Notwithstanding its energetic action, hydrosulphite of soda is not of practical use, owing to the strong smell emanating from its solutions.

Organic Hydrosulphites.—A study of the properties of hydrosulphite of soda led us to endeavour to prepare hydrosulphites of organic bases themselves possessing developing properties, in such manner as to obtain saline compounds of which the acid of a mineral nature and the base of an organic nature are both developing substances. Hitherto among analogous bodies only those were known which were formed by the combination of two organic compounds, one acting as acid, the other as base. In this class are included metoquinone (quinomet) and hydramine.

We succeeded in obtaining various organic hydrosulphites—at least, what the study of the properties of these bodies led us to suppose to be such, their instability, however, rendering analysis uncertain.

(1) **Hydrosulphite of Diamidophenol.**—By mixing equimolecular aqueous solutions containing equal quantities of chlorhydrate of diamidophenol and hydrosulphite of soda, a crystalline precipitate, formed of white flakes, is obtained within a few seconds. If the solutions are sufficiently concentrated the mixture resolves itself within a short time into a crystalline mass. Concentrated solutions of soda sulphite, soda bisulphite, or soda hyposulphite give no such precipitate with solutions of chlorhydrate of diamidophenol; we may therefore suppose that it is hydrosulphite of diamidophenol which is formed. Further, the study of the properties of the compound, purified by washing in water, in alcohol, and then in ether, confirms this theory. In fact, this compound possesses all the properties of diamidophenol and of hydrosulphite. If, after it is precipitated in the aqueous solution, one attempts to dry the crystalline mass on a porous brick, it becomes suddenly hot, gives off a quantity of sulphurous acid, and becomes a charred mass.

Quantitative analysis of the sulphuric acid in this substance, after oxidising the hydrosulphurous acid by bromine water, gives numbers nearly corresponding to, although slightly lower than, those equivalent to the formula

No certain conclusion, however, as to its composition can be drawn from analysis, as this substance is constantly losing sulphurous acid.

It is slightly soluble in cold water (solubility 1-600), but readily dissolves in sulphite of soda (solubility $2\frac{1}{2}$ per cent. in a 3 per cent. solution of anhydrous sulphite); it is but slightly soluble in alcohol, and insoluble in ether.

(2) **Hydrosulphite of Diamidoresorcine.**—Mixed solutions, even of low concentration, of chlorhydrate of diamidoresorcine and sodium hyposulphite produce a crystalline precipitate, which is formed under conditions similar to those existing in the case of such formation with chlorhydrate of diamidophenol, and which, when isolated and purified in the same way as the latter, contains at the same time the properties of hydrosulphurous acid and diamidoresorcine. Its solubility in water and in solutions of soda sulphite is similar to that of the product given by diamidophenol; it is as unstable as the latter, and constantly gives off sulphurous acid. Analysis of the sulphuric acid by the same means as before gave a result slightly below that corresponding to the formula

(3) **Hydrosulphite of Triamidophenol.**—Chlorhydrate of

triamidophenol (obtained by reduction of picric acid) in aqueous solution has a similar reaction on the solution of hydrosulphite of soda, and produces a crystalline precipitate, the formation of which is slower than in the case of diamidophenol and diamidoresorcine; its solubility in water is greater, and its other properties are similar to the two latter substances.

(4) **Hydrosulphite of Paraphenylene-Diamine.**—We succeeded in obtaining with chlorhydrate of paraphenylene-diamine and hydrosulphite of soda, working under the same conditions as before, a somewhat unstable crystalline compound possessing the properties of hydrosulphurous acid and paraphenylene-diamine. Its formation is less rapid, and it is more soluble in water than the compounds produced by the amidophenols.

Hydrosulphites obtained with Aromatic Monamines.—Operating in the same manner as with the amidophenols and diamines, we have been able to prepare unstable crystalline compounds with hydrosulphite of soda and chlorhydrates of aniline, of ortho and paratoluidine and of commercial xylydine, i.e., with bases not having developing properties. On the other hand, simple monamine-phenols and substituted products therefrom, such as paramidophenol and metol, gave no such compounds.

The Developing Properties of Organic Hydrosulphites.—We have tested the developing properties of the above-described new compounds. The constitution of those furnished with developing bases, such as diamidoresorcine, diamidophenol, triamidophenol, and paraphenylene-diamine, might lead us to expect these substances to possess great developing powers. We found that all these substances appear to act in practically the same manner. In simple aqueous solution they develop very slowly and give a feeble image, while they are but slightly soluble in water. If, however, they are dissolved in a solution of soda sulphite, energetic developers are obtained, but these give a deep fog, even when alkaline bromide and bisulphite are used. The compounds resulting from hydrosulphites and monamines do not appear to possess developing properties.

In short, pure hydrosulphite of soda, employed in the manner we have herein indicated, constitutes a rapid and very energetic developer, which may be used with the addition of a large quantity of sodium bisulphite without appreciably prolonging development; this, as we know, not being the case with organic developers.

On the other hand, the unstable combinations of hydrosulphurous acid with organic developing bases are of no importance as developers, and do not realise the expectations which might be raised by their constitution.

A. AND L. LUMIERE AND A. SEYEWETZ.

THE suggested formation of a photographic society for Cromer made a short time ago is beginning to take definite shape. Mr. D. Dulleys is acting hon. secretary pro tem., and it is intended to convene a meeting of all interested at an early date.

"LA FOTOGRAFIA ARTISTICA" is the title of a new international monthly review, which is published at Turin, and is the most sumptuous of all photographic monthlies that we have yet seen. The first number contains three full-page photogravures, a magnificent specimen of bromide printing, and a trichromatic print. The text is in Italian and French.

At the meeting of the Hackney Photographic Society, held on the 13th inst., two lantern slide competitions were decided as follows:—

1. For Set of Three Slides, "Scenes Typical of London Life."—Awards, First prize, W. Selfe; second prize, W. A. I. Hensler.
2. For Set of Four Slides from Negatives taken at Society Outings.—Awards: First prize, F. E. Roope; second prize, F. W. Burt.

A MORAL FOR THE NEW YEAR.

BY AN OCCASIONAL CORRESPONDENT.

In the early vagrant days of photography, when the elder ones of the present generation wore ankle-strap shoes and curls, an elderly barber in a Midland town invested in a camera and plunged into the "likeness business." We were primarily interested in him because his windows displayed penny toys—much more wonderful they were than those wonderful ones sold on Ludgate Hill. The old man was, in his way, a department store. He was a newsagent as well as toymen, and he took orders for funerals. His funeral cards (which he did not print, but was merely agent for) were in great demand. On Friday and Saturday evenings he opened a butcher's shop, and on Sundays he acted as assistant verger. How he managed to dovetail these and other businesses I do not know; the only rule I do remember was that shaving took precedence of everything; but all else, including hair-cuts, stood aside when a sitter came to the upper room which he called his gallery. There were no ethics to trouble his mind in those days; the amateur had not appeared on the scene, and so of course the associate question of "photographer and dealer" was still in the future. He went his way, untouched by any stress of modern competition, and when he departed this life he left his shop and two hundred pounds in the bank to his children.

A couple of seasons ago I went into the country for a holiday. Those who remember the summer of 1903 will not be surprised to hear that my holiday was one long downpour. I used to watch the rain trickling down the window panes, and listen to the wails of my landlord, who was the local photographer. We smoked a good many pipes together over the discussion of business, and I am sorry to say he taught me the reprehensible habit of smoking in the studio. Taking one time with another he ought to have cleared thirty shillings a week—that would have been a good "wage" in that locality, and his work was certainly not deserving of more than that wage, for it was the cheapest of uninspired commercialism. As it was, I doubt if he cleared half that amount, and he was in a grievous plight, for the wet season had washed away his hope of paying rent by lodgers. I was paying him twenty-five shillings for a week's lodging, and he could not afford to quarrel with that, and so I enjoyed to the full the pleasure of loading pompous good advice on a submissive listener. But he did not like it, and used to squirm and protest under my invective. Worst of all, his wife overheard us on one occasion, and, as lean fare was gradually turning the poor woman into a scold, she went for him after I had finished, and rubbed in pepper where I had merely supplied a little seasoning.

When I had been there four days, and wet misery had driven us to each other's company, and him to confession, I pointed out to him that, although he had spent four days without a single sitter, there was not a clean thing about the studio except the outside of the skylight—and the rain was to be thanked for that. How could he expect any self-respecting person to dress in a stuffy dusty room, and then lean against a dirty and broken rusty stile, when three miles away they could be photographed in clean surroundings, amid real palms, and by either the instantaneous or permanent process as required? If he had spent the four days in useful work, instead of idling, the studio would look presentable; and if he had always devoted a share of his dead time to keeping things in order they would never have come to the present pass, nor would trade have been so wretchedly bad. He swore amendment, and on the strength of it tried to borrow two pounds.

I left him at the end of the week. The last I saw of him he was gazing gloomily through the rain-bleared window. Probably he was thinking over his numerous good resolves.

About three weeks since I passed through this same village—hence this little story, as you will learn if you read to the finish. I called on my old landlord, and the first thing I saw

was a new show case, planted in the little garden before the house. It was home-made; and no great shakes at that, but it was a step in the right direction. The work in it showed that in whatever way my friend had improved, he had stood stock still pictorially—it was as bad as ever. I knocked at the door, and a man opened it—a man I had never seen before. He told me that poor Blanc had gone smash last autumn twelvemonth; and he had been running the business a year, and was contemplating matrimony. He was hopeful of making a good business. Eventually he wanted to clear a hundred a year for living expenses, in addition to rent. I went into the old studio and recognised old friends. A few stout nails and some paint had given a new lease of life to the rustic stile, and the upholstered chair had had the dust thrashed from it, and been treated to a new fringe. He had even attempted to make the old camera look respectable—with very indifferent success. But what struck me most was a personal attack. Before I had been with him ten minutes he told me I would vignette beautifully (sixpence a dozen extra for vignettes), and that I certainly ought to provide for posterity to the extent of a 12 by 10 enlargement, guaranteed permanent, and with as much hand work on it as was possible for four-and-sixpence. He was certainly what our Yankee friends term a "hustler," and before I quite knew where I was I found myself before the camera.

He told me that vignettes were very popular, and he showed me with much pride his snow pictures, which he hoped to display for the winter trade. He had covered an umbrella with cotton wool, and some spatter from a toothbrush did the rest. He had started a threepenny club for enlargements, and had eleven subscribers. It surely seemed as though he was on the high road to success.

His predecessor—who had never hinted at making a few shillings by photographing me—had drifted into the nearest town, and earned a precarious livelihood in an auctioneer's sale room. His wife, poor woman, swelled the scanty income by occasional day work.

And now for the moral. I think it is an obvious one; but one that has needed pointing to some people ever since the question was first asked: "Is photography played out?" And why have I told the story? Well, ostensibly to give a useful hint to some struggling men who find work slow to come. But between you and me and the Editor I have a more personal reason. I have a dozen vignette photographs which I dare not give to my friends; and I have a bromide enlargement which certainly shall not go down to posterity; and if I tell my story to THE BRITISH JOURNAL OF PHOTOGRAPHY I shall receive in return the needful to recoup me the amount I laid at the shrine of business enterprise applied to photography.

At the Birkenhead County Police Court last week, his Honour Judge Bowen Rowlands, K.C., heard two claims brought by an artist and photographer named R. T. Ford (Ford and Co.), of King Street, Egremont, for money alleged to be due for photographic work supplied. The first case taken related to a claim for three guineas for an opal enlargement against a Mrs. Billington, who lives at Penketh Road, Liscard. His Honour gave judgment for the plaintiff.—The second case was brought by Mr. Ford against a Southport lady named Mrs. Hargreaves. According to the case for the plaintiff presented by Mr. Hands, Mrs. Hargreaves called at the plaintiff's studio in November, 1901, and gave an order to Mrs. Ford for an enlarged photograph of her husband. The price of this was to be three guineas, and it was to be sent to defendant's address at Southport. About an hour and a half after Mrs. Hargreaves had left Mr. Ford received a note from her cancelling the order. Mr. Ford wrote back saying he could not allow this, as he had commenced the work. The enlargement was afterwards finished. Mrs. Hargreaves wrote refusing to pay for it. Judgment was given for the defendant, with costs.

THE GUM-SPLODGER.

"I TELL you there is only one process, and that is gum!" oracularly remarked the Gum-Splodger, as he laid down the law with determination.

"Umph! That's all very fine; for my part, I like a nice clean, sharp picture, and I like to know what I am looking at," returned the Dabbler.

"Well, you can get anything you want with gum; it is the one and only process for artistic results——"

"Oh, that's all nonsense. Gum is only of use for broad effects!" The Dabbler pulled at his pipe fiercely, snorting the while in disgust.

"Is it? I tell you you can get any effect with gum; I am tired of reiterating it. Use fine paper, and the picture is full of detail; use rough, and you lose it. I repeat, it is the only process for the artist."

"Yes; and how many gum workers are there who turn out a decent print?" the Exhibitor put in his spoke, shifting uneasily the while. He did not seem to promise conversion, to judge from his voice.

"Every worker can turn out decent prints with a little practice."

"Umph! You forget that in order to get a good print you must have a suitable—a thin negative——"

"Then reduce your old fogged things to a proper degree of thinness."

"You are very rude; let me finish! Then, again, in my opinion only about one in every twenty negatives is suitable for gum treatment," continued the Exhibitor.

"Yes, you have all the old fallacies at your finger ends, I see."

"Now, listen to me!" The Exhibitor knocked the ashes out of his pipe and sat upright. When he did that, it meant either he was going to be dreadfully severe, or say something very important. The Gum-Splodger listened and the Dabbler went on smoking in silence.

"I think this extravagant extolling of gum as the one and only process is doing a great deal of harm; its enthusiasts—as is often the way of enthusiasts—work their hobby to death and weary those who would be earnest disciples."

"You two are going to quarrel, as usual, I can see!" growled the Dabbler.

"Hold your tongue and listen, absorb the wisdom about to issue from my lips! This superiority of gum for anything and everything——" The Exhibitor frowned, paused to collect his thoughts. "Far be it from my wish to decry gum; I am well aware of its tremendous advantages, and there is nothing to touch it for certain things, but—I do think harm is done at the present time, and in this way: Men who are able to do good work in certain ways are being turned into messers in gum. What do we expect them to become? They are even told to ignore technique until they are full-blown artists (though there is reason, mind you, in the doctrine, if you look at it the right way). I have a quarrel with that first. What a world of masters we should produce on those lines in music, painting, and other things! Yet in photography, of all things—a craft that is built upon the mechanical, optical, and the chemical—oh! I have no patience!"

"And therein lies much of the trouble; you are the type of your intolerant set, and you are all much alike. No patience! That is the wisest and truest thing you have said so far."

"Well, now, about this gum. I tell you I think much harm is being done, and it is very sad."

"Go on, you always have something that is excessively illuminating to impart." The paster of sticky pigments was goaded a little; he sneered.

"You forget, you mad Gummer, it is only about one in

a hundred workers who can hope (often by a fluke) to turn out a good thing in gum. I know men, earnest and good workers, clever and artistic, who used to do the most beautiful things in carbon and platinotype; they have become bitten with this beastly gum fever, and are simply rabid. Now, instead of producing fine things in carbon and platinotype, they turn out hideous smudges in gum. It has spoilt many clever workers."

"Nonsense! You make yourself ridiculous!"

"Now they are Gum-Splodgers, and their prints—well! you never have a failure in gum; no matter how bad the thing is, it is a 'sketch'! So long as it is gum——"

The Exhibitor stopped suddenly, for the Dabbler was snoring and the Gum-Splodger was searching with uneasy eyes for a suitable weapon.

STINGER

THE PRACTICAL PERFORMANCE OF TRI-COLOUR FILTERS.

II.

Now to consider the character of the spectrum and chart reproductions in detail.

No. 1. Ives' Kromskop filters, in conjunction with a Lumière C plate. In these filters, which exhibit maxima most markedly, we have a much greater variation in the character of the record with variation of exposure than in any of the others, while the excessive overlap, more particularly between the red and green negative records, render the reproduction of the spectrum in the longer exposures very unlike the original. The region which is reproduced red extends in the second exposure into the green part of the spectrum, while in the longest exposure it only goes as far as the orange-red at wave length 6,300. The middle of the green at about wave length 5,500 is reproduced as yellow in the second exposure, while in the fourth the whole of the orange-red, yellow, and green from wave length 6,300 to wave length 5,100 is rendered as yellow. Green hardly occurs at all in any of the spectrum reproductions.

In the chart reproduction the bright reds are too orange, for the reason that they are somewhat recorded in the green negative, so that the crimson is not quite full strength, while the yellow is full strength. Yellows reproduce more or less orange because they are more recorded in the red negative than in the green, and hence have more crimson than blue-green printing upon them. Greens as such do not appear, while blues, not being sufficiently recorded in the green negative, are reproduced plus a good deal of crimson.

No. 2. Messrs. Sanger Shepherd and Co.'s filters, for the spectrum plate. These filters have abrupt absorptions, and show comparatively slight variation with exposure, the blue of about 4,900 is, excepting the highest exposure, reproduced as black, while the region rendered as yellow extends in the highest exposure too far into the green (up to 5,650). The regions reproduced as red, green, and blue-violet are fairly correctly placed, and the ultra-violet is almost entirely cut out. There is only a very small amount of red recorded, due to the plate recommended and used—viz., the Spectrum.

A general comparison of the chart with the spectra shows that in the reproduction of the chart the reds, not being well recorded, are too pale; the yellows are good; the greens have not enough blue ink on them because they are partially recorded in the red negative, and are also degraded with crimson. The dark blues show the effect of the unrecorded gap by being reproduced too violet in hue.

No. 3. Lumière (of Lyons) filters. In this case the red, green, and blue filters were used on the Lumière C, Lumière A, and Lumière extra-rapid plates respectively. With these filters, which have abrupt absorptions, there are no overlapping

regions, even with the highest exposure, so that the spectrum is reproduced by three isolated bands of red, green, and blue-violet. A drawback to such filters is the somewhat long exposures required.

The disposition of these bands is such that the light blues are about correctly recorded in the blue and green negatives, as one of the black gaps comes in the deep blue of the spectrum, and the green negative records the blue-green only. The black gap in the yellow and yellow-green causes oranges to be rendered too red, since the green in them is not recorded in the green negative. Dark greens, especially yellow-greens, are from the same cause much degraded with crimson. Yellows are too red because they are not fully recorded in the green negative; crimsons and purples are rendered well.

Nos. 4 and 5. Messrs. Farmer and Simmons' filters, published in "The Photographic Journal," June, 1901, for use with Lumière B for red filter, Lumière A for green filter, and Mawson and Swan lantern for the blue filter. There are two blue filters given, one to let the ultra-violet be recorded and the other to absorb it.

(There has been much conflict of opinion as to the advisability or otherwise of recording the ultra-violet. From a purely theoretical ground it cannot be correct to record any colour that is not seen by the eye in a three-colour reproduction, and the effect might easily be a bad one. If any colour but the blue and violet reflect much ultra-violet, they are bound to reproduce much lighter than they should—this actually is generally the case in light yellows and scarlets—and also the blues will be generally too dark, since the exposure might be sufficient before the blues had been fully recorded. However, much of the ultra-violet is said to be absorbed in practice by the lenses and glass used for filters, and in the reproduction of our test chart there is little difference between those filters passing the ultra-violet and those stopping it, when acting on dry plates, but still sufficient to be visible.)

In both sets the yellow band is shifted to much towards the green, owing to the red filter extending too far, and while it is true this will make the red filter much quicker, it is a disadvantage in the case of deep reds, as they will not be sufficiently recorded.

With the second blue filter region about 4,700 and extending in the higher exposures from 4,500 to 5,000 is rendered as blue, which is the dominant colour of that region, but the greater part of the violet is rendered as black. The most interesting point to be noticed with these two sets of filters is the manner in which the greens are degraded. In the case of the darker greens the insensitive band in the blue-green causes too much crimson to be printed on them, while with the light greens, the extension in the spectrum reproduction of the yellow into the green region of the spectrum indicates that too little blue ink is the cause of the light greens reproducing more yellow in tone than green.

No. 6. Mr. Klein's filters, for collodion emulsion. Filters recently prepared and lent for test by courtesy of Mr. William Gamble.

The red is correct, except that it records a band in the blue-green with long exposure. Green filter does not extend far enough into the blue, but is otherwise correct. Blue filter, probably a rhodamine, simply absorbs the green and with long exposure on the A sensitised collodion emulsion allows a band in the orange to record, producing there a light, almost white, band. In practice these two white bands would not, unless in exceptional cases, affect the result; still, one would have thought they might have been avoided without any sacrifice of transparency. With these filters the dark greens reproduce as brown, the light blues are too dark, and the dark blues too violet. The other colours reproduce well.

The remaining filters are liquid ones, all having been prepared

at the Bolt Court School, and used in glass cells having an internal separation of 5 mm.

No. 7. Collodion emulsion, sensitised with known colour sensitisers. Albert's emulsion, to which is added 4 cc. of pinaverdol, 1 in 500 alcoholic solution, per 100 c.c. of plain emulsion for yellow and red printer (blue and green filters), and for the blue printer (red filter) two parts of ethyl violet 1 in 500 alcoholic solution is added to 100 parts plain emulsion.

Blue filter contains:—

Quinine sulphate (solution effected with acetic acid)	0.5 per cent.
Victoria blue	0.1 "
Crystal violet	0.005 "

This cuts out all but between 4,000 to 5,000. This filter, however, is not stable and must be freshly made to give this absorption.

Green filter contains:—

Naphthol green	0.4 per cent.
Naphthol yellow	0.04 "

This records from 6,000 to 4,800.

Red filter contains:—

Fast red	0.05 per cent.
Tartrazin	0.25 "

This records from 5,800 to near the end of spectrum.

The green filter might, with advantage, extend a little farther towards the violet. The colours are fairly correctly placed, and the spreading with long exposures is entirely due to the nature of the film, since the same filters used on a dry plate do not spread to anything like the same extent. On the face of it the greens should record nearly as well here as in any filter; as a matter of fact they do not, neither in this case nor in the case of an even narrower green—Mr. Klein's. This would seem to be due to the contracted scale of gradation rendered with emulsion, since the same filter works very well with a dry plate that is much less sensitive to spectral green, the result being that, in the case of emulsion, whites and light colours are well exposed before greens and other deep colours have had sufficient exposure to be properly recorded.

No. 8. Sometimes, with direct work, the yellow printer is made on a wet plate and a plain water filter. The spectrum tests would lead one to suppose that pure blues would be reproduced rather too darkly and the ultra-violet recorded by the wet plate to give a violet tinge to all colours, other than blue and violet, that reflect it, which, as a matter of fact, does happen in the cases of raw umber, brown madder, and vermilion when unmixed with yellow.

No. 9. Bolt Court "A." The composition of filters we have used on dry plates (indirect method) is as follows:—

Blue filter, 0.5 per cent. quinine sulphate, used with a Castle plate.

Red filter, 0.25 per cent. Biebrich scarlet, used with a Lumière C plate.

Biebrich scarlet is not the best dye to use, owing to its requiring some alcohol to dissolve it, and we have since substituted:—

Fast red	0.5 per cent.
Tartrazin	0.25 "

This is made up to give exactly the same absorption. Rose Bengal could be used instead of the fast red, perhaps with a little gain in transparency and abruptness of absorption. We have such a filter made up to test its permanency.

The green filter for the red printing plate has been varied, as we shall describe.

In this set the green filter is acid green 0.05 per cent., quinine sulphate 0.5 per cent., used on a Westendorp and Wehner orthochromatic plate.

This green filter was adjusted to a typical erythrosin plate,

with its band of insensibility in the blue-green, so as to fill up this gap as far as possible, and at the same time to render perfectly the three inks used for printing. To do this the record extends more towards the blue than the yellow, in order to correct to some extent the usual want of transparency to violet in the crimson printing ink. The result of this is that in the spectrum reproduction the yellow is reproduced black, while the blue, although fairly correct in position, spreads with increasing exposure until it extends from 4,400 to 5,100. The extreme violet is also recorded slightly in the green negative, this is also reproduced as blue instead of blue-violet. In the chart the reds are well rendered with these filters, but the oranges are too red and the yellows too orange for reasons similar to those given for Lumière's filters. Dark blues are rendered too light, and dark greens, not being sufficiently recorded in the green negative, are degraded with the crimson ink. This set of filters is of interest in that, while they will reproduce the printing inks perfectly, they fail on other colours.

No. 10. Bolt Court "B." The same red and blue filters, and green filter made up as follows:—

1 per cent. solution of fast green B.S.	...	1.5 cc.
1 per cent. solution of tartrazin	...	1.5 cc.
1 per cent. quinine sulphate	...	100 cc.
Water up to	...	200 cc.

This green filter was used with the "Spectrum" plate, and was designed to give an even record throughout the yellow, green, blue, and violet of the spectrum, in order to prevent the crimson ink from printing in the blues, since, owing to the want of transparency of crimson printing inks to violet and the transparency to some extent of blue printing inks to red, the result obtained by printing these together is often not what it should be—a blue-violet colour—but a dark purple. In this series of reproductions the blue and blue-violet regions will be seen to be reproduced as blue while the reproduction has somewhat in the yellow.

With these filters the dark blues are somewhat too light with the inks used, but with the usual commercial blue inks they would be better. The two colours upon which this filter fails are yellow and green, neither being sufficiently recorded in the green negative by the time the whites are fully exposed, the blue and violet of the white recording as well as the green, the result in each case being the printing of too much crimson.

No. 11. Bolt Court "C." This is a green filter, designed to record evenly between 5,000 and 6,000. In this green and the next the records are pretty even throughout the exposures. The filter was made up of equal parts of naphthol yellow S.L. (saturated solution in water) and 0.02 per cent. naphthol green, and was used with the Spectrum plate. With this filter one would expect to see blues too dark, but the advantage of a narrow even green, correctly placed, is that average greens will be fully recorded on a normally exposed subject. Practically all colours were fairly well rendered by this except the dark blues, which were too violet, because they are not sufficiently recorded in the green negatives.

No. 12. Bolt Court "D." The green filter in this case records the yellow, green, and blue of the spectrum up to 4,600, where it commences to change to violet. The third spectrum of this reproduction is perhaps the nearest to the original in the whole series. The plate used for the green negative was again the "Spectrum," and the composition of the filter was as follows:—

Naphthol yellow	...	0.03 per cent.
Naphthol green	...	0.01 "

This filter gave the best general rendering of all those tried, the dark greens were only rendered as green with this and the preceding green filter.

A. J. NEWTON AND A. J. BULL.

PREPARING TRANSPARENCY PLATES BY THE ALBUMEN PROCESS.

ALTHOUGH the albumen process has fallen into desuetude, the following notes by Mr. A. J. Jarman, in "Wilson's Photographic Magazine," may induce some to try it:—

The quality of an enlarged negative depends in a great measure upon the quality of the transparency from which it is made. There are a number of methods that can be employed to produce a good transparency for enlarging purposes. The carbon process yields excellent transparencies when a special tissue is used, also wet collodion, and the gelatine dry plate. When the last-named plate is used a special plate is necessary, and the developer must be changed in its composition if the best results are to be obtained. A rapid gelatine dry plate produces a transparency possessing a considerable amount of grain, which, being magnified, produces in the enlarged negative a coarse and objectionable result. The consequence is that an enlarged print made from such a negative shows very clearly that it is an enlargement. The main cause of this is that the transparency from which the large negative has been made was defective. The difference in two prints of the same size, one made from a negative taken direct, and the other from an enlarged negative, is always apparent unless the transparency from which the enlarged negative has been made was faultless. The ordinary dry plate being ready at all times is generally used because it aids rapid production, but the results are only too often very indifferent in character.

It is well known to many of the older photographers that some of the finest results ever obtained in the way of enlarged negatives were produced when the transparency employed was made by the albumen or collodio-albumen process. The finest transparencies that have ever been made for the stereoscope were also produced by this process. A transparency produced by this means possesses the soft and delicate qualities of albumen combined with clear shadows and strong high-lights which characterise collodion. It possesses all the qualities necessary for the production of perfect enlarged negatives. The method of production about to be described will enable anyone to prepare the plates from which these beautiful transparencies can be made. The basis is a collodion film, which can be produced in two different ways. First by a collodion emulsion, and secondly by use of a solution of nitrate of silver in the usual dipping bath. The first plan is somewhat intricate, although it would be the best if the plates were to be made upon a large scale. The second method, being somewhat more simple and easily applied, will be described here.

In the first place, decide upon the size of the plates it is intended to use, procure a number of them, clean them well in a hot bath of common washing soda (about half a pound of soda to one gallon of water), rub them well upon both sides with a small mop made by wrapping pieces of clean, white rag upon the end of a clean strip of wood. Rinse the plates one by one in a stream of water, then place them in a clean tray containing a mixture of muriatic acid (one part to twenty of water). This will rid the plates of any trace of soda. Make up the following, which is to form the substratum for a preliminary coating previous to collodionising:—

Albumen (white of one egg)	
Distilled water	50 ounces.

Do not allow a vestige of the yolk of the egg to become mixed with the albumen. Shake this mixture vigorously three or four times during the day. Then, after allowing to stand over night, filter through two thicknesses of cheese cloth tied over the top end of a kerosene lamp chimney, so that when the chimney is inverted it can be inserted into a wide-mouth bottle or placed in one of the rings of a retort stand. This filtered mixture may now be poured into a glass graduate and the plates taken, one by one, from the acid bath, rinsed in a stream of water from a faucet, and one side of the glass coated, the excess of the albumen mixture being returned to the graduate by allowing one corner of the plate to touch the top of the graduate. The plate must now be placed in a clean rack to dry. The rule to be adopted in coating plates with a substratum is to coat the side opposite the diamond cut, because a glass-cutter who is a master of his business always chooses the rougher side for his cutting stroke. When the plates have all been coated and dried they are ready for the next operation of collodionising and sensitising. Procure a half-pound bottle of collodion ready

iodised—the longer it has been iodised the better—and make up a solution of nitrate of silver as follows:—

Nitrate of silver	2 ounces.
Distilled water	20 ounces.
Iodide of potassium	2 grains.

Shake this solution well, stand it out in the sunlight for one day, filter it into a glass dipping-bath, and it is ready now for use.

The following albumen solution must be prepared and kept ready at hand for use after collodionising. It should be allowed to stand for twenty-four hours after preparation and before being used. All albuminous preparations have to stand some time before they can be filtered and used to insure a thorough and intimate admixture of the albumen with the other ingredients, as otherwise the albumen will clog up the pores or meshes of the filtering material, and completely prevent filtration.

Albumen Solution.

Albumen solution (of fresh eggs)	8 ounces.
Strong water ammonia	2 drams.
Bromide of potassium	10 grains.
Iodide of potassium	50 grains.
Distilled water	3 ounces.

The albumen must be well beaten up in a clean basin with a silver or silver-plated fork until it is well broken up, the bromide and iodide of potassium must be dissolved in the three ounces of water, then added to the albumen, lastly the ammonia. This mixture can be filtered in the first place by tying a piece of cheese cloth over the top of a glass funnel, and rubbing the mixture through it with a small stiff bristle brush. After this operation, it may be filtered through the lamp chimney-filter already described. It is now ready for use, and must be employed in the following manner:—

Three graduates will be required, two four ounces and one eight ounces. Each four-ounce graduate must be filled with the albumen. The eight-ounce graduate is to receive the excess of solution after coating each plate. Now proceed as follows:—Take one of the dried glass plates, coat it with the iodised collodion, drain the excess into the bottle, move it to and fro in the air, to cause the excess of ether to evaporate, then place it upon the dipper and insert it directly into the nitrate of silver bath without stopping. These operations may be carried on under a deep yellow-coloured light, not necessarily under ruby light. Move the plate up and down in the silver bath a few times, then allow it to stand still for about two minutes, lift the plate up. If a 5 by 7 plate, grasp it by the sides between the middle finger and thumb of the left hand. Drain off the silver solution, wash both sides of the plate carefully in a gentle stream of water from the faucet. Allow it to drain for a few seconds upon one corner. Now apply enough albumen to just cover the plate, and drain this albumen into the eight-ounce graduate. Turn the plate around and again coat with albumen, this time taking the second graduate. Drain again into the eight-ounce measure. The plate must now be put in a very clean rack to dry. The use of the two graduates may now be easily seen. It is to prevent any possible contamination of the albumen in use.

Where a sufficient number of plates have been coated, stand them away in a dark, warm closet to dry. As soon as dry they are ready for the next operation, which consists of sensitising the plates once more. This will render the bromo-iodised albumen surface sensitive to light. To accomplish this another nitrate of silver bath will be required, made up as follows:—

Recrystallised nitrate of silver	600 grains.
Distilled water	20 ounces.
Glacial acetic acid	10 drams.

The plates must now be dipped into this bath and allowed to remain in the solution for five or six minutes, using a glass or hard-rubber dipper, the same as employed in the previous sensitising. The plate must now be washed well, and flowed over with a strong solution of gallic acid, the strength being near to saturation point. The plates must now be allowed to dry spontaneously in a warm closet. They may then be packed the same as ordinary dry plates or placed in a dry, grooved plate box ready for use. Great care must be exercised to prevent the surface of the plate from coming into contact with the fingers, as every mark will show upon the development. Transparencies may be made with these plates either by contact or in the camera. If made by contact the negative should

be first varnished. The time-exposure will be about fifteen times as long as that required for an ordinary gelatine transparency plate. It will be found to be an advantage to over-expose rather than under-expose, because the development can be kept well under control. It will also be observed that the acid nitrate bath will turn a reddish-brown colour after the plates have been sensitised, but this will not prove detrimental to the sensitising of the plates. Having made an exposure upon one of the plates, develop in the following manner. The solutions for pyrogallic development must be made up as follows:—

1.—Pyrogallic acid	192 grains.
Alcohol	2 ounces.
2.—Potassium bromide	24 grains.
Distilled water	2 ounces.
3.—Ammonium carbonate	160 grains.
Distilled water	2 ounces.

Take twelve minims of No. 1 in a clean glass graduate, one dram of No. 2, and six drams of No. 3. Rinse the plate in a running stream of cold water, drain off the excess, then with one sweep flow the developer over the plate. Rock the plate a little, return the developer to the graduate, then flow again. Keep the developer in motion upon the plate by tilting. The image will now quickly appear. It will look very different from an ordinary gelatine plate. The image will be very thin when viewed by transmitted light. It will be very full of detail, but may require strengthening. This is done by applying a small quantity of the following developer with a few drops of a thirty-grain nitrate of silver solution added.

Pyrogallic acid	12 grains.
Distilled water	6 ounces.
Citric acid	3 grains.

The first developer must be washed off and about half an ounce of the above used to flood the plate. It will be observed now that the image becomes very much strengthened. As soon as the required density is attained, wash the plate and fix it in a solution of hyposulphite of soda, four ounces to twenty of water. When fixed, wash the plate for about a half minute in a gentle stream of water. It may now be placed aside to dry. Upon examination it will be observed that the image is of a wonderfully delicate character, possessing all the beautiful gradation necessary for the making of a first-class enlarged negative.

Ferrous oxalate developer may be employed with these plates which also gives excellent results.

It may be advisable to point out here that care must be exercised in the practice of making albumen transparencies, particularly in the developing of the exposed plate, which is accomplished by holding it by the top left-hand corner after it has been wetted, then pouring only just enough developing solution upon the plate to cover its surface, and admit of its being rocked slightly, so that the developer can be made to flow forward and backward upon the plate. To undertake to develop in a tray like an ordinary gelatine dry plate is not at all necessary. The developer used for the albumen dry plate should never be allowed to come into contact with a tray that has been used for another kind of developer. The quantity of solution required for development is very small. It is also pointed out here for the benefit of those who are not acquainted with the wet-collodion process that the dipping bath and dipper referred to consist of a vertical glass vessel made in various sizes. The one best suited for the above class of work would be eight inches wide and ten inches high, so that a plate 8 by 10 could be inserted, the depth of the vessel being about one inch, all the above being interior measurements. The dipper also mentioned is made either of glass or hard rubber, the latter being the best suited for the purpose. This implement is for lowering the plate into the bath and lifting it therefrom without contamination from the fingers. The plate may be dipped into the nitrate of silver solution for sensitising, and withdrawn at will. When the sensitising is completed, the dipper should be returned to the silver solution and allowed to remain there at all times until required for use. These glass dipping baths and dippers can be purchased from any large photographic stock dealer, fitted into a suitable case with cover for their complete protection from breakage or the action of light. All these processes for a small amount of wet-plate work, as this process is called, may be carried out in

ordinary dark-room with ordinary caution, provided that no ammonia is permitted, as this would be liable to injure the plate of silver solution. All that will be necessary will be to set this class of apparatus in a separate part of the dark-room upon sheets of thick blotting-paper, so that any solution of nitrate of silver that may be spilled will be instantly absorbed. The little trouble necessary to the production of the albumen transparency will be amply rewarded by the production of a transparency that has never been equalled by any other known process. It must be understood that only part of the wet collodion process is necessary to carry out the work required has been described. There being no protosulphate of iron employed, nor liquid developer made up with the above iron salt, nor other chemicals are used in the wet-collodion process, an ordinary dark-room may be employed to prepare these special plates without fear of injury to the gelatine dry-plate process that may be carried on in the same room. Development of prints made upon paper sensitized by artificial light may also be carried on under these conditions. The slight odour coming from the ether and alcohol of the collodion will not be in the least detrimental.

Exhibitions.

SOUTHAMPTON EXHIBITION.

By A SPECIAL CORRESPONDENT

Year to year the progress made by the Southampton Camera Club is exemplified by the improvement of the members' contributions to the annual exhibition, and this year, both in quality and quantity, the advancement of the members' work is very striking. Indeed, the late Mr. J. C. S. Mummery and H. Snowden Ward (Mr. F. H. Ward was unable, through illness, to be present), took the unusual step of appending the following remark to the award list: "The Club is to be congratulated on a stronger show in the members' classes and a general improvement in the same." As in former years, the same system of free transit between the three "Southern" exhibitions of Hove, Southsea, and Southampton, the offering of a special award to the exhibitor whose collection of exhibits is deemed the best by the judges of all three exhibitions (which are different at each exhibition), and comprise nine of the most well known judges of the day, and the preparation of large and high-class quality plaques, with separate design for each club, has resulted in securing the support of the best exhibitors, and throughout the whole of the exhibits arranged in the admirably lit art gallery there are but a very bare number of even indifferent works, and none that could possibly be called bad.

The catalogue, which is well printed, on good paper, and includes no less than four bromide photographs, and no advertisements not directly connected with photography, shows that there are 722 exhibits, comprising 196 members' productions and the remaining 526 in the open classes. This does not include the postcard section, which comprises over a hundred very beautiful cards of all styles, and to the visitors a never-ending source of pleasant interest.

Dealing with the members' classes first and the names in alphabetical order, the first frames we notice are those of F. E. Allen, A. C. Berry, and R. C. Batt, the latter of whom received an hon. mention for his Swiss scene, "Brienzen." L. Besley takes the first award in the portraiture class, with his picture "The Brushmaker," and deservedly receives an hon. mention for his landscape "The Fisher," which is an early morning river scene of good composition and full of atmosphere. R. T. Christopher has several exhibits, the most noteworthy of which is an old doorway, titled "The Cloister Door," in which the light and shade has been carefully treated. C. C. Cook is a prolific exhibitor, and his series of exhibits are well worthy of careful notice. He receives an hon. mention for "The Gathering Storm," in which the tone values of the rocks and sea and sky are carefully preserved, resulting in a very pleasing marine study. His other landscape, "A Lonely Shore," is treated in a much lighter manner. His "R.P.S." frame, "A Street of the Past," also receives an hon. mention. He takes the club's plaque, and the special medal given by the Editor of the "Photographic News" for the best slides in the members' class,

with a series of four Normandy street scenes. C. Daw is to be congratulated upon securing his first award, with "An Entrance to the Nave, Winchester"; his portrait study, "The Duet," will also repay inspection. H. Essex has a good, but somewhat hackneyed, subject, "An Old Street, York," and he receives a medal for his landscape, "A Moorland Glen." G. Fidge has five exhibits, of which the best is "Declining Day." A. E. Henley is recognised as the best photographer of flowers in the club. As in last year, he takes the first award in the still-life class, with No. 129, "Anemones," a graceful arrangement, together with good lighting and careful handling, takes this plaque. His other two frames in this class, "Old White Roses" and "Luscious Grapes," also call for special mention. His large number of architectural studies are somewhat uneven in their results, but two or three of them must have run the winners very close. The brothers C. D. and W. R. Kay are accountable, and deservedly so, for a large number of the awards. C. D. Kay's No. 33, "A Forest Glade," not only receives the first award in the landscape class, but also takes a special award for the best picture in the members' classes, a silver medal, presented by the Editor of the "Amateur Photographer." In addition to these awards he takes the champion gold plaque for the best average club exhibits. His street scene in the architectural class are especially good, and if they err slightly on the score of heaviness this fault is fully compensated by the variety of treatment and different stand-points. W. R. Kay also has a large number of exhibits, and, without exception, each one is worthy of close examination. His landscape, No. 43, "The Close of Day," is certainly one of the gems of the exhibition. A long foreground effect, beautifully subdued, with a middle distance of rushes and an extreme distance of mountains, surmounted by soft and appropriate clouds, has produced a picture full of individuality, and one which may be studied with advantage by those who maintain that photography is nothing but a mechanical process. Others of his landscapes, "On the Hillside," "River Clouds," and "Golden Autumn," three totally different subjects, call forth nothing but the strongest admiration. In the portraiture class he receives a bronze medal for "Improvisators," but we much prefer No. 55, "Portrait of an Artist," the lines of which are especially pleasing and the composition gains from its very simplicity. Mr. Kay takes the first award in the architecture class, No. 99, entitled "A Glimpse of the Nave." This is a composition again essentially simple, and a strong lighting effect lifts it out of the commonplace. No. 81, "A Gray and Grief Worn Aspect of Old Days," deserves more than a passing glance, and No. 121, "Syringa," is the better of his two flower studies. A further plaque, and also an hon. mention, falls to Mr. Kay for lantern slides, of which he enters three sets, all of which are of extreme beauty and technically perfect. Unquestionably the best of Mr. G. F. E. Kenny's exhibits is his medalled picture, "The Ambulatory, St. Cross," which is full of vigour and sunshine without being aggressively strong. Mr. S. G. Kimber, the hon. secretary, has entered four of his architectural studies, all of which are well known, and although each of them has been medalled in other exhibitions no award has fallen to this worker.

Messrs. S. E. and W. A. Max Mills show three exhibits between them, all of good pictorial quality. Mr. H. W. Miles is to be congratulated upon receiving a silver medal for his picture "On the Thames," but the one we most admire of his ten exhibits is No. 132, "A Gray Morning, Windermere," a quiet, restful lake scene, in which the relative planes are carefully preserved and the title well borne out. Miss Powell's "Study of Hazel Nuts" could not be passed over, and Mr. W. H. Trigg's two exhibits deserved better hanging than they received. Mr. G. Vialls has a large and interesting number of frames. He receives a medal for his flower study, "Rowans," and an hon. mention for No. 54, "Question," which is a somewhat original study of an old man's head. His landscapes are well thought out and skilfully produced, and, in addition to No. 54, he has a first-class figure study in No. 65, "The Evening Sun," in which an old man is seated outside his cottage door with the evening sun striking on the paper he is reading. T. M. Weaver has three architectural subjects, one of which, "The Crypt, Winchester," receives a mention. No. 100, "To the Altar, Christchurch," is also a very capable rendering of an unusually difficult subject.

In the open classes J. A. Angus has a good thing in 221, "Harvest Time," as has J. B. Anderson in No. 556, "The Cloister Door, Melrose." C. H. Austin has four exhibits, including his picture medalled at the "R.P.S." A. H. Avery's "Day Dreams" is a great favourite with visitors, and he receives a plaque for his unrivalled little seascape,

"Homeward by the Evening Light." Herbert Bairstow's "Street in Rouen" is perhaps the most effectively mounted print in the exhibition, and he receives a mention for 532, "A Vegetable Shop." Miss E. M. Barrows, 490, "The Three Graces," is well known. Mrs. G. A. Barton shows seven of her inimitable figure studies, which must have placed her in a most favourable position, when the judgment for the "Special Award" was considered. She receives a plaque for No. 525, "A Country Gentleman," and her whole series is expressive of that individual treatment which we always look for from her and obtain.

A. Bedding's architectural works are not up to his usual high standard, only one, No. 595, "The Undercroft, Wells," being worthy of special mention. Mr. Graystone Bird shows several of his outdoor figure groups, and we congratulate him upon striking out a new style in No. 403, "Childhood's Joys," which unquestionably is the most attractive study of children in the exhibition. Arthur Black's "A Wayside Cottage," is one of the best things in its class, the strong sunlight on the figure and the cottage having been skilfully controlled, and the whole production is picturesque to a degree. J. Howard Burgess, 610, "Fleecy Flocks the Hills Adorn," is the best of his series; and Robert Burnie and G. A. Booth send some capital slides of still life and natural history studies. G. H. Capper shows two fine landscapes, 263, "Light at Eventide," a very pleasing wood scene, and 336, "Toilers of the Harvest," which is a well rendered and breezy cornfield picture. W. Clayden's, "A Gleam of Light," and W. A. Clark's three architectural studies are well known. Of the latter we admire "A Flood of Light" immensely, but think that about two inches of the right hand side of the picture might be trimmed off with advantage. Mr. Clark receives an hon. mention for his lantern slides. A. E. Coleman's exhibits are on original lines, his No. 398, "A Game of Nap," being a pattern for all makers of figure studies. P. W. Crane receives an hon. mention for No. 554, "To the Altar, Wirksworth," but we think this far behind his crypt study, which took an award here last year. One of the finest portraits ever exhibited is W. Crooke's "Sir Henry Irving," which is awarded a plaque. We would suggest that this print might be framed close up rather than with the broad ornamental gilt slip, which greatly detracts from the beauty of this fine masterpiece. A. de Silva's (548) "Torcello Cathedral" is a quaint piece of architecture. It would be impossible to praise too extravagantly Rev. H. W. Dick's set of slides, for which he receives a plaque. Mrs. Dumas, Dan Dunlop, and Miss M. C. Eames are responsible for some interesting exhibits, and C. E. Etches shows two of his soft, suggestive landscapes, which, year by year, we are accustomed to see and admire. G. H. Faux has four frames, of which No. 326, "Off Lowestoft," is infinitely superior to the others. D. M. Filshill's two exhibits compare favourably with that worker's usual productions, being far too heavy in tone.

R. Forbes, No. 512, "Waiting," is one of the most charming figure studies conceivable, and receives hon. mention. H. A. Game has entered only two frames, but what he lacks in quantity is more than compensated for in quality. His 288, "The Far Off Sun Darts Distant Beams," which receives an hon. mention, is a charming snow picture, the skilful massing of light and shade and the beautiful gradation being beyond all praise; and his other frame, No. 412, "Friends," is in nowise behind his snow picture in composition or technique. W. H. Goy sends two remarkably fine sets of slides, one of still life and the other of landscapes, which earns him an hon. mention. We must give expression to a feeling of disappointment as we examine Dr. Grindrod's numerous exhibits, as nothing in this present exhibition will bear comparison with the portrait of Sir Henry Arbuthnot Acworth, medalled here last year, and the frame selected for hon. mention, No. 492, "A Village Scholar," was, if we mistake not, exhibited here in 1902. C. J. Hankinson shows several delicately treated open air figure studies. H. P. C. Harpur has five entries, which, with the exception of his architectural study, are amongst the best in the exhibition. In his set of slides he has one, "The Bridge, Norwich," which for its rich quality has no superior. This is W. A. I. Hensler's first year as an exhibitor at Southampton, and his work, both frames and slides, is of sterling worth; his picture No. 251, "On the Hillside," receiving an hon. mention, and his 327, "Reflections," is in no way behind it in pictorial merit. His slides are patterns of what slides should be, although we would suggest that a warmer tone might be more appropriate to his landscape set. J. Hepburn, like Mr. Hensler, makes his debut at a Southampton exhibition, and we hope that he

will become an annual exhibitor. He shows seven figure studies, which for distinctiveness and simplicity of treatment have no superiors, a series, in the exhibition. For No. 500, "When Once Life's Drawn Near the Gloaming," he receives a plaque; and "Granny Tired Bairn," "The Village Doctor," and "Sunday Morning," are examples which gain from the fact that, although they represent subjects of everyday occurrence, they have been treated with such masterly hand as to entirely lift them out of the commonplace. A. Hill has a print in No. 334, which is of a very fuzzy nature. It is entitled "The Clouds Lay Cradled Near the Setting Sun." There is, however, such a feeling of vastness and strength that the somewhat obscure manner of representation is overlooked, and the beauties of the picture grow upon one with more intimate acquaintance. His other frame, "Mo Nighean," is a gum print of a somewhat peculiar portrait study, being possibly the nearest approach we have seen to the work of Demachy.

Harold Hood has a good thing in No. 246, "Cliff Dwellings," as does E. Hoppé, in the "Burden of Age" (454). Mr. C. B. Howdill's "The Sculptor" is too well known to require more than a passing word of praise, and Dr. Ivatt's "Old Archway, Norwich," deservedly receives an hon. mention. Miss Brenda Johnson's portraits are characteristically forceful, and No. 399, "Study of a Head," is a particularly attractive production. Fred Judge has a good quality landscape in 262, "November," and Ellis Kelsey takes a plaque with his lantern slide of night scenes. D. W. Kyle's flower studies show remarkably good technique. H. C. Leat has several exhibits, and we admire his rain scenes very much. Viscount Maitland sends one landscape and two figure studies, of which No. 445, "Study of a Head," reminds us very much of Romney's portraits. Arthur Marshall has a large collection of exhibits, and the judges of the Hove, Southsea, and Southampton exhibitions consider his the best collective exhibit, and have therefore given to him the special award. He also receives a plaque for a wonderfully attractive picture, "The Student," and a special hon. mention for the well-known picture, "Shadows." He also receives an hon. mention for No. 376, "Hauling Sail," and amongst his other frames is the "R.P.S." medalled picture, "Devotion." B. J. Mitchell has three exhibits, his slides showing good quality.

Bernard Moore has a good thing in 360, "The Ford," as has Paterson (468) "The Search." W. Northwood shows a good landscape in No. 346, "The Crest of the Hill." G. W. Perkins has a good study of rushing water in No. 335, "The Lotefos"; his other landscape "Evening on the Mawddach," is of a much quieter nature and very pleasingly mounted. O. G. Pike has several of his natural history studies, including 643, "A Story of Two Worlds," depicting in four prints the hatching of a chicken, from the cracking of the shell to the perkiness of a fully dried chick. Messrs. A. and F. Read have two exhibits, for one of which they receive a plaque. This is No. 322, "Shadows," and depicts a partially overgrown churchyard, among the tombstones of which the sun casts soft and illusive shadows. Bale Rider has a good landscape in No. 305, "November," and in this architectural class he deservedly takes the plaque with his charming picture, "In Gloucestershire." Dr. G. H. Rodman shows a large number of very first-class radiographic slides of molluscal shells. W. H. Rogers has two landscapes, and the poorness of No. 358, "Woodland Pool," is amply compensated for by the soft and picturesque "Waning of Day," No. 343. Mr. F. R. D. Scroggs has four exhibits, all of even quality, although his picture (280), "Threshing Thro' It," is, of course, the best known.

As far as we are aware, Mr. E. Seymour is not an old exhibitor by any means, but there is no denying that his this year's still life productions have stamped him as one of the best flower photographers we have. Indeed, there has been no more consistent medal winner in this year's exhibitions than Mr. Seymour. He receives an hon. mention for his "Chrysanthemums" and his "Currants," and in a greater degree his "Nettles" are triumphs of still life photography and the admiration of all the visitors to the exhibition. C. J. Sheath has a good sunny landscape in No. 353, "In the Calm Dew and Freshness of the Morn." John Spark has three exhibits. His picture, "Impensive Mood," No. 381, is a wonderfully clever production, and must have run the winners in the portraiture class very close. J. Stabb's slides of "Lightning," and Dr. W. W. Stanthorpe's and L. J. Steele's frames and postcards are well worthy of studied attention, and Miss Hilda Stevenson's portraits are among the most attractive in the class.

H. Gordon Stollard has a particularly good thing in No. 295, "A Sussex Lane," and P. G. Terras' (417) "A Spanish Maid" is one of our greatest favourites. Mr. F. G. Tryhorn's slides are of splendid quality, and he receives an hon. mention for them. B. Ward Thompson shows two large frames, being photographs of a collection of old lustre ware, and he must have applied very considerable skill to have obtained such perfect technical results as he has.

T. E. Waltham, E. B. Wain, Rev. E. G. Watts, and W. H. White each show a number of exhibits, which will more than repay a passing inspection. J. M. Whitehead sends four exhibits. As would naturally be expected, they are all of the highest possible standard. Indeed, Mr. Whitehead gains the distinction of being the only exhibitor in the open classes who has been awarded two plaques. The first of these is given him for No. 354, his well known picture "Desolation," and the second is won in the flower class for his equally well known decorative study, "La Tulipe." Mr. B. C. Wickison's "The Vesper Hour," will always be received with intense admiration. It occupies the centre of one of the walls of the gallery, and has received an hon. mention. H. Wild's and H. Wormleighton's slides are of the best, and if T. Wright's exhibits are not quite up to his usual standard they are, nevertheless, of very excellent quality. A. B. Fellowes-Prynn receives a plaque for a smart little dog study of excellent technique, entitled "On the Qui Vive."

The postcard class is composed of a large quantity of very beautiful work. A. W. Cooper receives the plaque for his "Woodland Mist," which is one of a very fine series submitted by this worker; and Rev. E. T. Clarke takes the second award for "The Lavatorium, Gloucester."

Space prevents the mention of many workers whose exhibits are a continual source of enjoyment to the visitors at the exhibition, and whose work is extremely good and interesting. The complete list of awards is appended.

LIST OF AWARDS. Members' Classes.

Class F.—Landscape, River Scenery, and Marine.—Plaque: C. D. Kay, W. R. Kay. Mention: C. C. Cook.

Class G.—Portraiture and Figure Studies.—Plaque: L. Besly. Medal: W. R. Kay. Mention: G. Vials.

Class H.—Architecture.—Plaque: W. R. Kay. Medal: C. Daw. Mention: C. C. Cook, T. M. Weaver.

Class J.—Flowers, Animal and Natural History Studies.—Plaque: A. E. Henley. Medal: G. Vials.

Class L.—Members who have never won an Exhibition Award.—Silver medal: H. W. Miles. Bronze medal: G. F. E. Kenny, H. Essex. Mention: L. Besly, R. C. Batt.

Class K.—Lantern Slides (any subject).—Plaque.—C. C. Cook, W. R. Kay. Mention: W. R. Kay, H. Essex. Gold plaque for best average exhibits: C. D. Kay. Silver medal presented by the Editor of the "Amateur Photographer," for the best picture in the members' classes: C. D. Kay. Silver medal presented by the Editor of the "Photographic News," for the best set of slides in the members' classes: C. C. Cook.

Open Classes.

Class A.—Landscape, River Scenery, and Marine.—Plaque: A. and F. Read, J. M. Whitehead, A. H. Avery. Special mention: Arthur Marshall. Mention: B. C. Wickison, W. A. I. Hensler, H. A. Game, Arthur Marshall.

Class B.—Portraiture and Figure Studies.—Plaque: W. Crooke, John Hepburn, Arthur Marshall, Mrs. G. A. Barton. Mention: Dr. C. F. Grindrod, R. Forbes, Herbert Baisrow.

Class C.—Architecture.—Plaque: P. Bale Rider. Mention: P. W. Crane, Arthur Marshall, Dr. E. Ivatts.

Class D.—Flowers, Animals, and Natural History Studies.—Plaque: J. M. Whitehead, A. B. Fellowes Prynn. Mention: C. E. Walsley, E. Seymour.

Lantern Slides.

Class E.—Any Subject.—Plaque: Rev. H. W. Dick, Ellis Kelsey. Mention: W. H. Goy, R. Burnie, W. Farren, F. G. Tryhorn, W. A. Clark.

Postcards.

Plaque: A. W. Cooper. Bronze medal: Rev. E. T. Clark. Special award for best collection at Hove, Southsea, and Southampton exhibitions: Arthur Marshall.

SEFTON PARK PHOTOGRAPHIC SOCIETY.

THE sixth annual exhibition of this society was opened last week. The society has now eighty-one members, and the collection on view this year includes nearly 200 exhibits, divided, according to subjects into classes, eight for members only and three open. The awards, adjudged by Dr. J. W. Ellis, Dr. Thurston Holland, and Mr. C. F. Inston, are as follows:—Class A: Three excursion prints, H. E. Cubley (silver medal); three ditto, F. B. Bolshaw (silver medal); "Lym Lake," "An Old Gate," and "On the Shore," by Thomas Robinson (bronze medal). Class B: Woodland study by W. Riding (silver medal); "An Idyll," by J. Seddon (bronze medal). Class C: "Maidenhair" (portrait), by Herbert Broad (bronze medal). Class D: "A Norman Font," by H. E. Cubley (silver medal); "In Birkenhead Priory," by A. W. Parr (bronze medal). Class E: Set of lantern slides, by H. E. Cubley (silver medal). Class F: Set of slides for beginners, by A. W. Parr (bronze medal). Class G: For enlargements not retouched, "When Earth and Sky and Sea do meet in one harmonious glory," by W. H. Tomkinson (silver medal); "A Misty Morning," by C. N. Ellis (bronze medal). Class H: Contact prints, "Sandhills," by F. Massey (bronze medal). Class J (open for juniors): "Cousins," by F. B. Simpson (bronze medal). Class K (open pictorial): "Apples," by E. Seymour (silver-gilt medal); "Chemical Industry," by J. W. Towers (silver medal); "Winter," by J. E. Latham (silver medal); "Winchester Cathedral," by S. G. Kimber (bronze medal). Class L (open lantern slides): H. Wormleighton (silver medal); F. G. Tryhorn (bronze medal). Class M (open champion class): "A Gleam of Light," by W. Clayden (silver-gilt medal); "A Shaft of Light," by S. G. Kimber (silver medal). The exhibition will remain open during the evenings of the present week.

FORTHCOMING EXHIBITIONS.

December 28-31.—Wishaw Photographic Association. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January 12-14, 1905.—Boston Camera Club. Hon. Secretary, H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Mitchell, 180, Browning Road, Manor Road, E.

January 23-28, 1905.—Lancaster Photographic Society. Hon. Sec., R. T. Simpson, 21, Cheapside, Lancaster.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 16-18, 1905.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 25, Bank Street, Hillhead, Glasgow.

February 25-March 4, 1905.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11, 1905.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14, 1905.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

April, 1905.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15, 1905.—Photographic Society of Ireland. Hon. Sec., R. Benson, 35, Molesworth Street, Dublin.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
26 to 31...	Boro' Poly. Photo. Society	Tenth Annual Exhibition.
27.....	Nelson Photographic Society ..	Open Night.
27.....	Hackney Photo. Society	Photography Slides.
28.....	G.E.R. Mechanics' Institution	Silver Printing and Toning.
28.....	North Middlesex Photo. Soc.	Technical Meeting.
29.....	Watford Camera Club	(Scenes on the Pennsylvania Railroad.
29.....	Richmond Camera Club	Mr. W. H. Rau.
29.....	Leigh Photographic Society ..	Paper by Mr. G. Ardaser.
		The Amateur Prize Slides (1904). The Secretary.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On the 15th inst. Mr. Human read a paper on "Colour Sensitised Plates," illustrated with lantern slides, made upon the majority of colour sensitive plates on the market, a Reeves' water colour chart being used as the test, and supplemented with a number of fine flower studies.

Mr. Rapson said that the pot metal screens used by Mr. Human would contain a certain amount of black, which to some extent would influence the colour rendering, neither depth of colour, or tint, or the exposure ratio being any guide as to the true amount of colour correction a screen would give, a commercial screen he had, with a ratio of six, giving less colour correction than one dyed with ammonia picrate with a ratio of two only. Mr. Dyer pointed out that a ratio of, say, five, with one batch of plates, would require seven, or perhaps two, with another batch of plates, even by the same maker, and also was of opinion that the idea so often put forward that colour sensitive plates without a screen were better than an ordinary plate in taking a sunset, was not according to fact. The chairman said that better results upon colour sensitive plates were obtained in a bright light than in a dull one when using screens.

The hon. secretary announced that on December 29 Mr. Herbert Starnes would read a paper, entitled "A New Printing Process."

CROYDON CAMERA CLUB.

FOLLOWING his exposition on "Intensification," a note of which appeared last week, Mr. T. M. Sellors explained and illustrated a means of surfacing bromide prints, originated by himself, and apparently new, so far as the immediate purpose is concerned, although a somewhat similar method has long been employed for the so-called "fixing" of crayon and other handwork on the surface. The method in question, at first sight, may seem to be an heroic one and fraught with danger to the picture, but in Mr. Sellors' hands this was not so. It consists in partially melting the gelatine in the emulsion by means of steam, projected on to the image from a pipe in connection with a closed vessel containing water vigorously on the boil. An ordinary kettle, if its spout extends upwards, will suffice, but is inconvenient in use. Mr. Sellors showed a rough and ready appliance, constructed out of a tobacco tin, which served its purpose admirably, a tube about eight inches long, rising straight, with its free end bent over at an angle of about 45 degrees, being soldered to the lid. The jet of steam is directed on to the print, and the latter kept constantly on the move; the gelatine in the emulsion is thus brought almost to the melting point and acquires a semi-gloss, which is in a great measure retained. Heavy shadows—which so often show an inclination to be sunken—are thrown up and the whole image brightened and enriched to a remarkable extent. On the other hand, the dead matt surface—should it exist in the first place—naturally disappears, but what is lost in this direction may be more than compensated for in the other. With the very rough papers, owing to the small quantity of gelatine they contain, the effect is not so pronounced. The method in question is also applicable to carbon prints, provided they have not been alumed. It would appear desirable to temporarily attach the print to be operated upon to a board or other support somewhat larger in size. Mr. Sellors omitted to do this, and having inadvertently introduced his thumb between the orifice of the pipe and the print skipped like a little lamb for a second or two, much to the edification of all present.

During the evening the president (Mr. S. H. Wratten) informed the members that Messrs. C. E. Kenneth Mees and S. E. Sheppard had been unanimously elected honorary life members of the club as a token of appreciation of their photographic research, which was received with considerable applause.

New Materials.

The "Vivid" Flash Powder. O. Sichel and Co., 52, Bunhill Row, London, E.C.

This new powder gives an extremely brilliant flash and ignites quickly. It is sold in a wooden box, the lid of which serves to measure out the required quantity. To ignite the powder a small piece of paper is crumpled up and placed on the heap and the edge lighted. As soon as the flame reaches the powder the flash goes off. The powder should be placed on a piece of tin or an iron shovel. We prefer the latter as it can be held at a convenient distance without danger to the operator. The powder must not be used in confined magazine flash lamps.

"Titelitt." O. Sichel and Co., 52, Bunhill Row, London, E.C.

Here we have a new method of titling negatives. The outfit consists of a sheet of glass on which are about a thousand small opaque letters, with which is also a bottle of cement. To title a negative, the letters required are removed from the glass plate and cemented to the film side of the negative. The process is simplicity itself, and the letters absolutely permanent.

Patent News.

The following applications for Patents were made between December 5 and December 10, 1904:—

Colour Photography.—No. 26,573. "Colour photography." Edward Russell Clarke.

Development Apparatus.—No. 26,660. "An apparatus for facilitating the development of photographs in daylight." Frederick Harriott Goodwin.

Dark-Room Lamps.—No. 26,864. "Improvements in and relating to photographic dark-room lamps." Ernest Adolf Jahn.

New Books.

"The Optical Dictionary." Edited by Charles Hyatt-Woolf, and published by the Gutenberg Press, Limited, Fleet Street, London, E.C. Price 4s.

A compilation giving the meanings of the chief terms in visual and photographic optics. Each item necessarily receives the briefest notice, but perhaps one feature of the book which will particularly recommend it to students of optics is the inclusion of synonyms for technical terms used by writers on optics in French and German.

"Pour les Débutants." By MM. C. Puyo and E. Wallon. Published from the office of "La Revue de Photographie," 44, Rue des Mathurins, Paris.

Photography is not mentioned in the title, but the names of the authors and the place of publication sufficiently indicate to those who casually take up this little work that it is a text-book for the photographic beginner. It is the second of the series of manuals which is appearing under the supervision of the talented editorial committee of our handsome contemporary, "La Revue de Photographie." In the first Major Puyo described his own practice of the gum process, though why the committee did not persuade M. Demachy to take people into his confidence is a legitimate matter for inquiry. Now Major Puyo associates himself with M. Wallon, and the result is a workmanlike volume for the beginner, neatly produced, and with a few well-chosen illustrations.

Commercial & Legal Intelligence

SUMMONED at Marlborough Police Court on December 16 for exchanging for sale improper picture cards and stereoscopic slides, Alfred Rose and Alfred Coop, of 65 and 135, Regent Street, W., were each fined £20, with five guineas costs.—Solomon Goldstein, of 335, Weston Road, for a similar offence, was fined £10, with three guineas costs.

J. EDMUNDS AND CO., LIMITED.—The above-named company has been registered, with a capital of £1,000, in £1 shares. Object: to acquire the business of chemists, druggists, dealers in photographic apparatus, magic lantern manufacturers, opticians, etc. No general public issue. Registered without articles of association. Registered office, 33, High Street, Kingsland, N.E.

BREACH OF CONTRACT.—*Birmingham Photographic Company v. Birmingham, Shaw, and Co.*—This case came on for hearing at the Birmingham Assizes on December 16, and was an action in which the plaintiffs claimed of the defendants, who are shipping agents in Liverpool and London, damages for breach of contract. Mr. Wills and Mr. Sandlands (instructed by Messrs. Newey and Sons) appeared for the plaintiffs, and Mr. Hugo Young, K.C., with Mr. J. G. Hurst instructed by Mr. E. F. Freeland for the defendants. Mr. Wills announced, on the case being called on, that the cause had been withdrawn on the terms that defendants should pay the plaintiffs £100 and costs in settlement. Judgment for £100 and costs was entered.

A PHOTOGRAPHER Sent to Goal.—At the Ilkeston Petty Sessions on Thursday last, George Edward Shardlow, photographer, 10, Hadfield Road, Ilkeston, was charged on remand with being the bailee of a piano, value £19 8s., the property of Messrs. G. A. Gray and Co., London, and feloniously and fraudulently converting the same to his own use, at Ilkeston, on April 15. Mr. J. Ormond, solicitor, Ilkeston, appeared to prosecute, and said Mr. T. H. Richardson, auctioneer, of Ilkeston, was bringing a case before the court in the interests of the public and of auctioneers, who from time to time were defrauded. Defendant, it was alleged, obtained a piano on the hire system, and then took it to Mr. Richardson to be sold by auction. On going to receive the purchase money, defendant declared and signed a document that the instrument was his sole property, and he received a cheque for £11 3s. 6d. from the auctioneer, £2 6s. 6d. having been deducted for commission, goods sold, etc. Mr. Richardson had paid £11 11s. to Messrs. Gray as a compromise to their original demands. Defendant pleaded guilty, and Mr. H. Thorpe, solicitor, asked for leniency. The magistrates' clerk then altered the charge to obtaining a banker's cheque from Mr. Richardson with intent to cheat and defraud. Shardlow was sent to prison for three months, with hard labour.

LUDWIG LANDMANN, 7, Tivoli Road, Crouch End, v. Charles Joseph Parr, managing director of Parr and Co., Limited, 130, Westminster Bridge Road, and Gordon James Jack, manufacturer, 10, Queen's Square, Southampton Row, W.C. Claim for £24 in respect of wrongful dismissal. Mr. Beaumont Maurice appeared for defendants. Mr. H. Dobb, counsel for plaintiff, said his client was a photographer, sensitiser, and photographic chemist. He was in possession of a secret for preparing certain sensitive paper used for photographic purposes, and also by architects. Defendants were anxious to get hold of this secret, and they engaged him, an agreement for six months being entered into on June 7, 1904. As time went on defendants seemed to have some suspicion as to whether plaintiff was giving them the true secret of his process, and they employed a lad to watch him, and he (counsel) would show that they were all the time negotiating behind his back with another man to come and take his place. One Monday in September plaintiff stayed away, as, being a Jew, he was desirous of attending an important feast, and on returning to work on the Tuesday he was at once dismissed. Mr. Beaumont Maurice raised an objection that the action was wrongly founded, inasmuch as in August the business was taken over by a limited company. The dismissal took place in September, and therefore the company ought to have been sued. Plaintiff said it was only on the day of his dismissal that he heard of the limited company claiming the right to discharge employees at a

moment's notice. Charles Joseph Parr, one of the defendants, said the company was formed on August 24. Two days later he informed plaintiff of the fact, and, further, that if he did not keep better time it would mean instant dismissal. At the end of a legal argument his Honour said he was sorry to decide that the action was wrongly founded, but he felt that the evidence of Mr. Parr was certainly the strongest, and ought to be accepted. He must enter a nonsuit, with costs to defendants.

A CASE Adjourned.—A case was mentioned at the Barnsley Borough Court on Thursday, in which Dennis R. Thompson, photographer, of High Street, Sheffield, charged Edward Dawes, photographer's manager, of Doncaster Road, Barnsley, with embezzling the sum of £10 on November 26. Mr. Carrington, the magistrate's clerk, said he had received a letter from the complainant asking that the case might be withdrawn, but he pointed out that the charge was one of felony, and felony could not be summarily compromised in that manner. He advised the Bench to adjourn the case, and two others in which the same complainant was interested, for a week, and in the meantime he would communicate with the complainant with regard to his attendance at court. It seemed to him (Mr. Carrington) that he was seeking to use the court as a debt-collecting agency. Mr. Rideal, who appeared for Dawes, said there was no doubt that had the case gone in the ordinary way, his defence would have been that it was a matter of account. His client was a collector with complainant, and during the time the snow was on the ground he met with an accident, and lost some of his money. He reported the matter by letter, and he had paid his employer certain moneys for which he held receipts. Afterwards a summons was taken out on December 6 for £8, embezzled on November 26, which amount was clearly and altogether wrong. Mr. Rideal read a letter written to defendant subsequently, showing an amicable relationship, and handed up to the Bench the receipts to which he had referred. The Mayor: What about the Inland Revenue? These receipts are not stamped.—Mr. Rideal: Yes, I know, sir. He added that Mr. Thompson was right in the letter he had written, but he (Mr. Rideal) did not want any suspicious circumstances to attach to defendant. The Mayor said they would follow the advice of their clerk. They were not going to allow the court to be made into a debt-collecting agency, and were not going to allow Mr. Thompson or anyone else to settle felony outside the court.

AN Appeal Dismissed.—In the Court of Appeal on December 16, before the Master of the Rolls and Lords Justices Stirling and Mathew, was an appeal by the plaintiff, Mr. Thos. Corns, from a decision of Mr. Justice Grantham in an action brought for a declaration that he was entitled to a rescission of a contract to take 500 preference shares in Paul Boyer, Limited, a French company now in voluntary liquidation; and he also claimed damages against the defendants, Lord Dunmore and Count Max Hollander, as directors, for breach of duty and negligence, and for an indemnity against any claims which might be brought against him by the liquidator of the company. At the trial the point raised was similar to that arising in the case of "Sir William Broadbent v. Dunmore and Others," that preceded the present case in his lordship's list, and which resulted in a verdict and judgment being entered for defendants. It was therefore agreed by counsel when this case was called on that the judgment in Sir William Broadbent's case should be binding upon the parties in this, but without prejudice to the plaintiff's right to come to the Court of Appeal. Mr. Asquith, K.C., and Mr. J. R. Willis (instructed by Slark, Edwards, and Co.) appeared for the appellant; Mr. Eldon Bankes, K.C., and Mr. Martelli (instructed by Messrs. Beyfus and Beyfus) for Lord Dunmore; while Mr. Rufus Isaacs, K.C., Mr. Gore Brown, K.C., and Mr. E. Ford appeared for Count Max Hollander. It appeared from the statement of Mr. Asquith, for the plaintiff, that there was no allegation of fraud made against any of the defendants. The only question was whether as to the plaintiff's application to become a shareholder, being, as his case was, subject to a conditional precedent that a certain number of the shares should be taken up in France before shares were allotted him, which condition was not, he said, fulfilled. He was now entitled to recover from the defendants the £250 which he had paid in respect of his application for shares. Their lordships, at the close of the arguments, held that the appeal failed on every ground against all the defendants, and they accordingly dismissed it with costs.

News and Notes.

WILLING'S Press Guide for 1905, which is just to hand, is the thirty-second annual issue of an extremely useful compilation of all the newspapers published in the United Kingdom and Ireland, and also of the leading American papers.

THE death is announced of Mr. A. W. Allard, who was formerly in business as a professional photographer at the Abbey Studio, Tewkesbury. At the time of his death, which took place suddenly at Cheltenham, Mr. Allard was proprietor of the Plough Hotel.

EASTMAN Kodak Company of New Jersey.—The usual quarterly dividends of $1\frac{1}{2}$ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding Preferred stock and of $2\frac{1}{2}$ per cent. (being at the rate of 10 per cent.) upon the outstanding Common stock have been declared by the Eastman Kodak Company of New Jersey, payable on January 1, 1905, to stockholders of record at the close of business on November 30, 1904.

DONCASTER Camera Club.—On Tuesday the seventh meeting of the season was held at the Albany Hotel. Mr. H. G. Snow gave a lecture entitled "Round the North Welsh Coast with a Camera," which was well illustrated with about sixty lantern slides, amongst them being a series of very fine sunset studies, the clouds being on the same plate as the landscape. The usual vote of thanks to the lecturer was proposed by Mr. Sutcliffe and seconded by Mr. Yates.

SOUTHPORT Photographic Society.—The members of this society heard a very enjoyable lecture on Thursday evening by Dr. Payne, entitled "What I saw in Norway." Dr. Payne gave an interesting account of a fortnight's tour in Norway, illustrated by a large number of lantern slides shown by Mr. Cross. Mr. D. Edmondson Benson presided, and there was a large attendance. Thanks were passed to the lecturer, on the proposition of Mr. R. Todd, seconded by Mr. E. Webster, and supported by Mr. C. H. Brown. It was decided to send a letter of condolence with Mr. J. Lambert on the death of his mother. The Secretary (Mr. Cross) was instructed to invite prints of views of old Southport for the album which was to be prepared by the society.

THERE were sixty-one entries for the four competitions held by the South London Photographic Society at their last meeting. The first to be decided was the Lecturette Slide Competition for views taken on the society's excursions, the silver medal going to H. C. Beckett for an architectural detail set, second and third awards going to E. W. Taylor and J. F. Gardner. In the Beginners' Class for four slides, also from excursion negatives, V. Emmett was adjudged winner. For a print representing "Eventide" the award went to Gideon Clark, and for the best print by a member who had not previously taken any award T. Milburn was successful. Messrs. Tryhorn and Clear, of the West Surrey, were the judges, and at the close Mr. Tryhorn gave a short address on the competition in general. He said what had struck him most was the lack of tonality in the majority of the slides. The distances were often rendered as strongly as the foreground, and in some cases most unsuitable skies had been printed in. In many cases also the camera had been placed far too high, which caused the foreground and the middle distance to appear as if on the same plane.

INDUSTRIAL Alcohol.—Some of the European Governments, which have at hand the means of making alcohol in large quantities at small cost, have undertaken to encourage the manufacture of spirits. The Emperor of Germany, for instance, has given the matter some considerable personal attention, and has offered prizes for efficient designs of engines and lighting apparatus making use of alcohol. The result has been that great strides have been made, and the new devices are used to quite a large extent. The same thing has been done to a minor degree by the Russians, but it has been discovered to be a lamentable fact that, as the manufacture of alcohol increased, the amount consumed as a beverage also grew lamentably larger and larger. The alcohol habit has taken such a hold on the Russians, that recently the Imperial Minister of Finance offered a prize of 50,000 roubles, which is equal to \$25,750, for the discovery of some means by which the alcohol would be rendered so distasteful that it could not be consumed in this manner. Pamphlets giving the conditions of the award have been distributed among the Russian

Consuls in the various countries of the world, and it is hoped to stir up a universal interest in the contest.—"Scientific American."

THE annual report of the Paris Observatory for 1903 deals with a number of researches of special interest. The seventh section of the Atlas of the Moon has appeared, containing seven plates which seem the most successful yet issued, and in some respects to show considerable advance over the best views of the moon obtained by the eye at the telescope. With respect to the Astrographic Chart eleven plates have been passed as satisfactory, and thirty-five charts containing the triple images of 47,300 stars have been distributed. It is hoped that the second volume of the Photographic Catalogue will appear by the end of the current year. The determination of the solar parallax from the photographic observations of Eros is advancing toward completion. Of standard stars 1,661 meridian observations have been made, and 10,858 photographic observations of comparison stars, of standard stars, and of stars near the path of Eros. Three important researches based upon new methods are included in the programme for the future work of the observatory: the first relates to the determination of latitude and of its variations; the second is for the precise determination of the constant of aberration, two portions of the sky, distant 90 deg., being presented in the field of the instrument at the same moment by means of a double mirror; and the third relates to the employment of M. Lippmann's photographic object-glass in meridian observations.

COPYRIGHT in America.—The following is taken from the "Standard" of Saturday last:—"Through Laffan's Agency, Washington December 16.—The Copyright Bill passed by the House of Representatives gives the author or the proprietor of a book published in a foreign language, belonging to a nation extending similar privilege to the United States, the right of copyright in an English translation or dramatisation made within twelve months after the first publication of the book in the foreign country. The Bill has yet to pass the Senate." The statement from Washington that the House of Representatives has passed a Bill granting foreign authors the privilege of copyright has been read with considerable interest in London. This the more so because those most interested in the question here were unaware that anything was being done in America at the moment. The last official communication between the English Society of Authors and the United States in reference to copyright was on March 29 in this year, when Mr. Thring, secretary of the society, forwarded to the United States Copyright League report of his sub-committee on the amendment of the United States Copyright Law. The present state of Anglo-American copyright is governed by the Act of 1891. By that measure a system of reciprocity was supposed to be established, and English authors were enabled to copyright their works in America by conforming with certain somewhat stringent requirements. Those demanded of American writers in England were not so severe, and the genuineness of the reciprocity has often been called into question. The Americans have benefited enormously since the Act by the sales in England of works of many of their best-known authors. There is no reason to suppose that they would lose, however, if an Act were passed which would automatically confer the copyright in America upon works of English authors and *vice versa*. Indeed, the strongest champions of a new Copyright Bill are the big American publishers." It will be noted that this applies only to literature, no mention being made of artistic works.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

THE ASSOCIATION OF PHOTOGRAPHIC EMPLOYEES.

To the Editors.

Sirs,—I would esteem it a favour if you would allow me to announce your columns that I have been appointed (provisional) Hon. Secy. of a (proposed) new organisation to be entitled the "Association of Photographic Employees," which will, I feel sure, meet the requirements of the various correspondents who have inquired about such an organisation.

The main idea is to meet the employers in a sympathetic spirit, and to strive mutually for the uplifting of the calling. All employees who can produce two signatures (with addresses) testifying that they are bona-fide employees in commercial photography are eligible to join. The payment suggested is 1s. as entrance fee, and 6d. per week subscription.

Benefit when unemployed will also be paid to those who join that section and pay extra for said benefit. For the present, membership of this section is limited to persons (of both sexes) under forty. A sick benefit section will also be added in due course.

All who desire to help should commence by sending their names for registration, and 1s. towards our initial expenses, to—Yours faithfully,
GEORGE PALMER.

20, Bishopsgate Street Without, London, E.C.
December 13, 1904.

ALL INVOLVING THE ABOLITION OF EXEMPTIONS AND ABATEMENTS OF INCOME TAX.

To the Editors.

Gentlemen,—I have read with surprise the extraordinary recommendation of the Central Board of the Traders' Defence Association that "All limited liability, joint stock, Civil Service, Army and Navy, co-operative societies shall be treated as units for the purpose of collection of Income Tax *without rebate* to the individual members shareholders thereof." This body has even gone to the length of sending a Bill for submission to Imperial Parliament calling for legislation to that effect.

Now, the Traders' Defence Association, it was generally understood, was appealing to the Committee, now sitting, to consider the incidence of Income Tax, to rectify the alleged abuse of the non-assessment of co-operative societies. In this, their endeavour, I was heartily at one with them, and quotations from a book of mine were widely in the public press in support of the movement. The Traders' Association, apparently not wishing to receive where they did not give, have now offered in exchange for £500,000 the amount it is estimated the Government is losing by non-assessment of co-operative societies—to give a sum of, say, six millions sterling. Now the proposed gift is at the hands of the small investor, and is probably one of the most extraordinary suggestions which have been made for many years past by a presumably responsible body.

The result of the passage of such a Bill through the Houses of Parliament would be that every penny deducted by the secretary of a company from dividends would be irrecoverable.

The widow, for instance, who had £150 a year from investments could pay £7 10s. in Income Tax, which sum would not be recoverable, as at present. Again, the labourers' savings, whatever his income, would oblige him to pay the tax on the fruits of, perhaps, his ceaseless toil and commendable thrift.

It would be absurd to suppose that a Bill of such a character could even receive the serious consideration of the House. It would doubtless be blocked at a very early stage. Still, it is a grave danger to the community that a representative body which is receiving general support, should incorporate—presumably to appease—their recommendations one so drastic and ill-considered.

In 1902-3 the Income Tax exemptions and abatements allowed exceeded £167,000,000, whilst the total deductions allowed exceeded £71,000,000. It may be assumed that the Association was scarcely

aware of the far reaching extent (millions would be affected thereby) of this recommendation, and will not be unprepared to evacuate an untenable position.

Another clause of the Bill is to the following effect:—"Any such society (joint stock, co-operative, etc.) declaring no dividend, but giving the benefit of profit to its members or shareholders in any other form, shall be taxed on 10 per centum of the annual turnover or value of business done." Is it suggested that:—

(1.) There is no such thing as a loss in business;

(2.) An assessment of 10 per cent. on turnover is a fair estimate of the net profit of the average business.

It would be interesting to put this latter question to tradesmen, great and small, in a variety of businesses.—Yours faithfully,

T. HALLETT FRY.

Manager, Income Tax Reclamation Association.

14, Queen Victoria Street, London, E.C., December 19, 1904.

THE ALKALINE DEVELOPMENT OF P.O.P.

To the Editors.

Dear Sirs,—In an article in to-day's B.J. you are good enough to say that "one of the simplest formulae" for development "is that suggested by the Paget Prize Plate Co."

Will you permit us to point out that our connection with the matter is much closer than this would seem to imply; the whole process of alkaline development of P.O.P. having been first made possible by us in 1893. In the B.J. of that year, page 562, there is a description of a demonstration of the process made for the first time at these works, in the presence of several representatives of the photographic Press; and on page 672 of your paper, 1904, in an article on the same subject, containing the following statement:—"Proceeding on the lines of the old silver development methods on silvered paper, acid development with either pyro or gallic acid had been found superior in every way—although far from perfect in its action—to any alkaline method, until Mr. W. J. Wilson demonstrated the possibility of successful development by first converting the silver chloride in the paper into bromide. Then, at last, the difficulty of developing printing-out papers disappeared."

The matter is not one of any great importance, but as the process, whatever its value, has been more than once attributed to other sources, it may be as well, for the sake of historical accuracy, to keep the facts on record.—We are, dear Sirs, faithfully yours,

PAGET PRIZE PLATE CO., LTD.

Watford.

December 16, 1904.

METRIC WEIGHTS.

To the Editors.

Dear Sirs,—Your "Ex Cathedra" leader states that no dealer of photographic material stocks the metric weights. No doubt that is correct, but they can easily be procured in this country, and at a very reasonable price.

When last I read a paper on the metric system before the London and Provincial Photographic Association, for which I was fiercely attacked in the photographic Press, I showed a set of weights such as can be easily procured in Paris, and I obtained to order of members of the said L. and P. Association about two dozen sets of these weights, ranging from 1 centigram to 100 grams, for a mere trifle.

If amongst such a society as the L. and P. there are to be found some twenty members who take the first opportunity of obtaining these weights, how many must there be amongst the general body of photographers who would seize the same opportunity if it was offered to them?—Yours truly,

J. R. GORTZ.

215, Shaftesbury Avenue, W.C.

December 15, 1904.

A FIRE broke out last week at the photographic supply house of Messrs. O. H. Peck and Company, Minneapolis, U.S.A., and spread to the adjoining furniture house of Messrs. Boutell Brothers. A high wind carried the conflagration through a closely-built retail district, causing losses estimated at over three million dollars. Assistance arrived from St. Paul, and the flames were checked.

Answers to Correspondents.

- * * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- M. D. Morley, 91, Belgrave Road, Leicester. Photograph of the Leicester Town Walls.
- W. L. Allison, 13, Donegall Square North, Belfast. Photograph of the Rev. T. Yates.
- A. J. Siedle, 29, High Street, Newport, Mon. Photograph of the late Rev. M. Bailey.
- B. G. Brock, 237, Wellingboro' Road, Northampton. Photograph entitled "Winter."
- W. H. Warburton, Harris Promenade, Douglas, Isle of Man. Photograph of the Douglas Town Council Sitting in Council Chamber at Municipal Buildings.
- S. H. Greenway, 27, Abington Street, Northampton. Photograph of the Northampton Town Football Club, and Photograph of the Northampton Football Club.

"C. B."—We beg to acknowledge the receipt of your letter, and, whilst we sympathise with you on the unfortunate result, we congratulate you on having remained firm not to sign the iniquitous document.

BURNISHER.—"G. H. T." asks: "Could you tell me where I could get roller of 'Globe' Burnisher repolished, and about cost of same?" In reply: You had better inquire from Jonathan Fallowfield, Charing Cross Road, London, W.C., who, we believe, is the agent for the "Globe" Burnisher.

PICTURE FRAME MOULDINGS.—W. FINCH says: "Would you kindly inform me in BRITISH JOURNAL OF PHOTOGRAPHY, if possible, two or three firms of picture-frame moulding manufacturers, etc., preferably English, cheap and good, reliable for one starting in small way in the country, that makes to order and supplies materials, including gilt for oils?" In reply: If you will look in our advertisement pages you will find the announcements of several makers of picture-frame mouldings.

WORKS ON HALF-TONE AND TRI-COLOUR WORK.—C. R. DODD asks: "Which is the best and most complete work on half-tone process work and tri-colour work, and who are publishers, and where am I likely to be able to purchase?" In reply: We should recommend "The Half-tone Process," by Julius Verfasser, price 5s., and "Three-colour Photography," by Häbl, translated by Klein, price 7s. 6d., both published by Penrose and Co., 109, Farringdon Road, E.C., who could supply.

CRYSTAL PYRO.—"SUBSCRIBER" says:—"Kindly let me have the address of where I can procure pyro in transparent crystals. I suppose it is German. I refer to article, 'Pyrogallic Acid and its Use,' page 1065, BRITISH JOURNAL OF PHOTOGRAPHY this week." In reply: Pyro in crystal form can be obtained from any large dealer in this country, and doubtless also in France, whence our querist writes. One brand is made by Merck, of Darmstadt.

COPYRIGHT.—"PROFESSIONAL" writes: "(1) If I take a photograph and register same, then grant a firm 'sole right for post-card use,' would I be in a position to sell the copyright of that photograph to any one else? (2) The same query as above, only instead of 'sole right' I only grant 'use for post-cards'? (3) Does granting 'sole right for post-cards' debar the author and owner from reproducing the photograph in post-card form?" In reply: (1) You can only assign copyright for purposes other than post-card. (2) If by "use" you mean the assignment of copyright for a particular and specified series of cards, you are at liberty to dispose of the copyright in other directions for post-card purposes, but such assignments should be drawn up in writing and the terms of sale clearly stated. (3) Certainly it does.

PHOTOGRAPHIC CHEMISTRY.—"PHOTOGRAPHER" writes: "I want study chemistry, both from a photographic and scientific point of view. Can you inform me:—(1) Title and price of a book on photographic or other chemistry? (2) Can I obtain a book or pamphlet, etc., giving a list of all known chemicals? (3) Or poisons and antidotes? (4) There is a book published and used by all chemists containing formulas approved, I believe by the Pharmaceutical Society. Can this be obtained commercially, and from where, and at what price? (5) Can you give me the name of a wholesale firm or manufacturer who could supply almost any chemical? Our photographic chemist cannot. (6) Is it a fact that a limited company retail poisons although no qualified chemist is employed? Or that any one can supply scheduled poisons wholesale? (8) Some plates are stated to be orthochromatic. What does this mean? Is it exactly the same as isochromatic?" In reply: (1) Meldola's "Chemistry of Photography," Toxend's "Chemistry for Photographers," Roscoe's, or one of the many other manuals of elementary chemistry may be studied. (2) You had better get the list of chemicals from one of the large manufacturing chemists, such as Messrs. Harrington Bros. (3) No such book is published. There is a number of standard works dealing with the chief poisons. Consult the list of a publisher of medical works. (4) I refer to the Formulary recently issued by the "Pharmaceutical Journal." Particulars of the terms on which it is supplied can be obtained from the office of our contemporary, Bloomsbury Square, London, W.C. (5) Merck, of Jewry Street, London, E.C., or Baird and Tatlock, Cross Street, Hatfield Garden, E.C. (6) A certified chemist must be employed. Yes. (8) Commercially speaking, the terms "isochromatic" and "orthochromatic" signify the same character of color sensitive plate.

"ENLARGER" writes: "I have an enlarging apparatus, as enclosed photo, which has not been put to its full use, and has only been used for daylight enlarging. Having spent considerable time experimenting without success, I would be obliged if you would answer the following queries through the medium of your inquiry column:—(1) What are the correct positions each part? (2) When used in the following way, the image of mantle shows in centre of image of negative—why is this? (3) What distance should burner and negative be from condenser? (4) Is one Welsbach burner suitable as source of light? (5) The condenser is 10 inches diameter, and is understood, only suitable for negatives to be enlarged from size up to 8 by 6—why, then, are there arrangements 15 by 12 inch negatives—can I not also enlarge these? If how? Is condenser any use for these? (6) Can any lens be used for enlarging? The one with apparatus does not clearly, the edges being all out of focus. For daylight enlarging I have used a Ross No. 2 Universal, which gives very satisfactory results. (7) There are also two stands with paratus; what use are they to be put to? A is evidently large enlargements, but I am not clear about B; is it negative making?" In reply: (1) The order of the parts of the baseboard should be as follows:—Condenser, ground glass, negative carrier, lens, dark slide. (2) By adjusting position of the ground glass between the condenser and negative you should be able to prevent the image of the mantle showing in the enlargement. (3) The position of the burner from the condenser should be fixed (by trial) so as to get clear, evenly-illuminated disc. The negative may be placed close to the condenser (the other side), but the exact position is not important. (4) Yes, for fairly thin negatives, but exposures may be inconveniently long if the negative is a dense one. For this a Nernst electric lamp is the illumination to be named next in order of convenience. (5) A 10-inch condenser will take a whole plate negative, not larger. In the case of a 15 by 12 plate, you can enlarge only from an 8 by 6 portion of it. (6) As a general rule, a lens which will cover a plate of the size to be enlarged, when photographing in the ordinary way will answer properly in the enlarging lantern. (7) The pivot stand is apparently intended for use in enlarging from negatives which suffer from the distortion caused by tilting the camera without swinging the back.

EX CATHEDRA.

Hydro-sulphite. Hydrosulphite of soda, on which MM. Lumière and Seyewetz wrote last week, was used in the developer as an anti-stain before its developing properties *per se* were pointed out by MM. Lumière before the French Photographic Society. L. O. Lammann recommended its employment with the pyro developer in these pages in 1877, and we believe he was the first to mention the compound in photographic literature. But he does not appear to have noticed any particular advantage from substituting hydrosulphite for sulphite. Hydrosulphites are powerful bleaching agents, and one use for them which at once suggests itself to us is in discolouring dyes such as are used in the daylight development of plates or in the preparation of plates rendered anti-halation by a coloured substratum.

The Two Hyposulphites. MM. Lumière, in their paper, adopt the old name, "hydrosulphite," originally given to the compounds by their countryman, Schützenberger, who discovered them in —. But the name now generally adopted is "hyposulphite," as hyposulphurous acid comes next to sulphurous acid in the series of sulphur acids. Our universal hyposulphite is the thiosulphite of the chemist. The distinctions should be borne in mind in looking up the chemistry of the compounds which MM. Lumière regard as possible developers.

Catatype. In further perfecting the method of contact printing without light which was originated by Professor Ostwald, Dr. O. Gros now recom-

mends the conversion of the silver image of a negative on glass or paper into one of the higher oxides of manganese. His object appears to be the production of an image which retains its chemical acidity towards hydrogen peroxide for a greater time. The treatment recommended consists in the employment of a solution of manganese peroxide in excess of tartaric acid with the subsequent addition of sufficient caustic soda to render the liquid alkaline. Or a solution of potassium permanganate may be mixed with sodium tartrate solution so as to leave an excess of the latter. Whichever mixture is employed, the print is afterwards washed for a short time and transferred to an alkaline solution of potassium ferricyanide.

The New Patent Law. On January 1, 1905, the new patent law comes into operation, which may be briefly said to be the institution of a system by which, on an applicant lodging a complete specification at the Patent Office, a full and careful search will be made by the examining staff among all patents taken out within the last fifty years, in order to ascertain whether the invention claimed is really new. If a prior patent is found, which more or less anticipates the invention, the applicant will be apprised of it. He can then either amend his specification or argue against the Controller's opinion. If, after hearing the arguments, the Controller is still of opinion that the applicant is anticipated by the prior patent, he will have the power, subject to an appeal to the law officer, to cause a reference to be inserted in the specification to the prior patent. The value of this system will depend obviously on the examiners; but we think that there is no safeguard against the patenting of a well-known principle or a fact which has long been common property through prior publication in the journals.

The Humours of Ballooning. The Rev. J. M. Bacon, whose death we very much regret to record, was as much at home on the lecture platform as in the car of his balloon. Many photographic societies will have lively recollections of his discourses on aerial photography and of his enjoyment of the comic side of his adventures. On one occasion, when scanning the country for a spot on which to descend, the choice fell on a clear paddock which stood with some buildings in a walled area. The premises turned out to be a lunatic asylum, and the aeronauts were cordially received by the superintendents, with whom they stayed to dine, after their balloon had been packed up and ignominiously sent home by train. After dark, Mr. Bacon and his companion were setting out from the gates of the asylum when the watchman stopped them. "Where are you going?" "Back to town," was the reply; "we came this afternoon." "Not through here," opposed the watchman, suspecting de-

serters. "Oh no, we came in a balloon." "Ah," was the watchman's answer, as he closed the gate, "I've heard that before."

Another Art Addition to the Royal Exchange.

Gradually the panels at the Royal Exchange are being filled up with the works of the greatest painters of modern times, such as Millais, Sir Frederick Leighton, and others of similar note, presented by generous donors, amongst whom are some of the City Companies. On Monday last week the Lady Mayoress, accompanied by the Lord Mayor and Sheriffs, unveiled a new one. This is painted by Mr. Edwin Abbey, R.A., and was presented by the Merchant Taylors' Company and the Skinners' Company. A large number of persons do not appear to be aware of the fine works of art that are to be seen in the City. Apart from the fine pictures, frescoes, in the Royal Exchange, there is a most excellent (permanent) collection at the Guildhall by some of the best masters. It is open daily, and the admission is free, for the Corporation, whether with its loan exhibitions, or its permanent one, does not stoop to "gate money." It is thought by some that the only idea in the City is the making of money, but if they visit its art shows they will see that the Corporation have consideration for more than mere money making. It hopes in time to make its art collection still more worthy of the greatest city in the world than, it must be confessed, it is at present, good as it is.

"Pyro" and its Uses.

Referring to our article on this subject a fortnight ago, the query from a correspondent which we replied to last week suggests the usefulness of a few further remarks. It is evident from the fact that any one should write to ask where the crystalline form was obtainable, that pyro in that particular form is not well known, and this is rather remarkable, seeing that its use spells economy, and we know too well that in most studios of late every means of "saving a penny" has usually been well thought out. But it is so very easy to buy an ounce bottle of the old form, fill it up with water, give the whole one or two shakes, and have a solution ready to hand at once. Yet it must be remembered that, though the bottles are not "charged for," yet they are paid for by the buyer. Half-pint, wide-mouthed corked bottles are not given away in tens of thousands for nothing, and the price of a pound of pyro in one-ounce bottles ("bottles free"), even buying wholesale, will be found to be quite 30 per cent. above the cost in tins of one pound; in other words, the money that will buy sixteen ounces in bulk will only suffice for twelve separate ounces in bottles—a loss of at least half-a-crown in the price of a dozen! This half-crown and a further sum (from eighteenpence upwards) are saved by the use of the crystals (bought in bulk), which, as we said, cannot be distinguished in use from the old kind. We may add a slight caution. The crystals are very soluble; still, their dissolution is not so virtually instantaneous as the flocculent form, and it is desirable to watch the disappearance of the crystals (an occasional shaking is all that is needed), as, otherwise a portion might remain undissolved at the bottom of the bottle, and so the solution vary in strength as the residue gradually got taken up by the water.

The Cheapening of a Rare Metal.

Some of our readers will be able to recall to memory the time when metallic aluminium was a chemical curiosity, priced in the lists at so much the grain. The progress of invention has gradually brought its manufacture to such a

state of perfection that it is now not much dearer than copper, weight for weight, while bulk for bulk it is actually cheaper. It is, as we need scarcely say, much used in photographic work, though in many ways it is an unsatisfactory metal to work or to use. Later, the so-much-grain price of magnesium metal became reduced to less than a shilling an ounce, and as such it has been largely used in photographic purposes for the brilliant light with which it burns. Little further use was made of it till its combination in the alloy named magnalium was put on the market, this alloy being in every way superior to aluminium itself, though it has not made much headway popularly. We believe, however, it is largely used in certain Government manufacturing departments. The latest rare metal to be brought to a popular price is calcium, which, though priced in last year's list at half-a-crown a grain, we learn can now be obtained in quantities at 12s. per kilogram, that is to say, a little over 5s. per pound. It is early to speculate to what use it can be eventually put in matters photographic. It melts, according to Watt's Dictionary, at a full red heat, and then burns with a yellow flame and production of much heat and light; does not oxidise in dry air, but in ordinary air is quickly coated with lime. It decomposes cold water rapidly. In the first edition of the same work magnesium is described in somewhat similar terms, save as to the colour of the flame. We may hope to hear something about calcium in alloy as an analogue of magnesium.

A New Mode of Dissolving Platinum.

Many of our readers are, no doubt, familiar enough with the process of dissolving gold to obtain home-made chloride, and they will have found it tedious enough to get the whole of the metal into solution, that is to say, where the metal is in bulk, such as in the form of gold coin, etc. Gold precipitated from old toning baths is quickly dissolved. If they try platinum the time occupied is still more prolonged, though, as a matter of fact, we have not met with any who in their use of platinum employ any form but the bought crystals of whatever salt containing the metal that they use. Hence the interest will be theoretical rather than practical, with most of our readers, in learning that a new mode of dissolving platinum has been published by MM. André Brochet and Joseph Petit in the "Bulletin of the French Chemical Society." In Series 3, Vol. XXXI, No. 12, they describe their method. They make use of an alternating current of electricity through strips of platinum immersed in solution of cyanide of potassium, and in their "Conclusions" say, "Platinum therefore is easily dissolved in cyanides under the influence of an alternating current. This point is the more interesting as this metal offers a special resistance to chemical agents. The cause of this solution, which could not have been predicted, appears to us to be of great theoretical interest." One of the costly but necessary adjuncts of Röntgen-ray work is the platino-cyanide screen. Possibly MM. Brochet and Petit's investigations may lead to some reduction of price here, for they further state: "Our researches have led us to the establishment of a process for the manufacture of platino-cyanide, particularly that of barium," and they describe the intricate and troublesome method which only has been available up to the present.

Some Unexplained Phenomena.

Some years ago Dr. W. J. Russell observed peculiar photographic effects, which seemed to be connected with a radiation given off by hydrogen peroxide. The radiations passed through paper, gelatine, celluloid, and ebonite, and

L. Graetz, of Munich, announces in the "Physikalische Zeitschrift," that the rays can also penetrate through thin foils of silver, gold, and aluminium. The effects cannot directly be due to vapours of hydrogen peroxide. This is, indeed, hardly likely, because the peroxide is less volatile than water, and can be concentrated by evaporating aqueous solutions. Graetz obtained images when placing the metallic object at the back of the photographic plate while exposing the sensitive front to the radiations from hydrogen peroxide. The phenomena are perplexing, however. Thus he found that metals give bright pictures on dark ground, and liquids dark pictures on bright ground. On further investigation it resulted that objects or portions warmer than their surroundings turn out bright, and colder portions dark. Temperature differences of 0.02 deg. Cent. can be distinguished in this way. The edges of the pictures differ, moreover, from the central portions, which may be brighter or darker. It would appear that those parts become bright towards which the heat flows, and those parts dark from which the heat flows. We have, therefore, apparently a radiation with a polarity. Without expressing any opinion as to the primary cause of the phenomenon, Graetz thinks that both hydrogen peroxide and heat have something to do with the effects. Ozone is generally thought of in such phenomena, and it has recently been suggested again by Schenk and Richarz that ozone will photograph and will produce electric discharge and phosphorescence. Dry ozone, Graetz, Ladenburg, and Aschkinass maintain, however, has none of these effects.

Albumen Transparencies for Enlarging From.

In our last issue was reproduced, from "Wilson's Photographic Magazine," an article by Mr. A. J. Jarman, on the preparation of transparency plates by the albumen process. There is no question that albumen transparencies are admirably suited for making enlarged negatives from, but whether, in practice, they are better than those by other and simpler methods—say, the carbon, for example—may be somewhat doubtful. Few reading Mr. Jarman's article will, we imagine, be induced to make albumen transparencies by the troublesome method described by him. This method is the old collodio-albumen process, not the albumen process proper, which, by the way, is simpler to work—only the sensitising of the plate being required—while the results for the object in view are the same. However, if any one should be inclined to experiment with the former process, we will here give a few hints that may save them some little trouble, because the directions as given in the article quoted are not in accord with the process as it is, or rather was, worked in this country. In the first place the preliminary coating of the glass with albumen is quite unnecessary if the glass be thoroughly cleaned. Mr. Jarman says the sensitising of the collodion film must be done in the dark room, and the plates also dried in the dark. This, also, is quite unnecessary. Workers of the collodio-albumen process know quite well that all the operations up to the sensitising of the albumen film may be done in full daylight, as the iodised albumen undoes any action the light may have had on the sensitised collodion. The proportion of bromide to iodide is larger than was usually employed by the best workers here—some used none at all—while the silver bath given for the albumen coating is much weaker. The silver bath employed by them usually contained forty-five grains of nitrate of silver and forty-five to fifty minims of glacial acetic acid to the ounce of water, and the solution was also saturated with iodide of silver before it was used. We should fully expect that, if the bath given by the author of the article in "Wilson's Magazine" was used with-

out this being done, the iodide of silver in the film would be dissolved away in the silver solution in the five or six minutes, the time given for the immersion of the plate in the solution. From half a minute to a minute is the time usually given, and no more. We have not used the developer recommended by Mr. Jarman, it is true, and shall not be inclined to, as we should prefer an acid developer somewhat similar to that given by him as an intensifier. It was the practice with some workers, who used to employ the collodio-albumen at the time it was so largely in vogue, to immerse the plate, in the first instance, in a weak plain solution of pyrogallie acid—or one with a drop or two of ammonia added—until a faint image appeared, and then complete the development with an acid pyro developer, to which a drop or two of a solution of nitrate of silver had been added. If any one is inclined to utilise albumen transparencies for producing enlarged negatives from, we should advise them to read the articles, "The Albumen Process in Practice," which appeared in our volume for 1903, pp. 264,323. These were written for the production of lantern or stereoscopic slides. What was then said applies equally as well to transparencies for enlargement if the toning be omitted. The fixing may also be omitted. Some long time ago the production of albumen transparencies for enlarging from was sold as "a secret process," and in that a point was that they should be used without being fixed.

We have to announce that with this issue of the JOURNAL Mr. Thomas Bedding, F.R.P.S., retires from the position of Editor-in-Chief, which he has occupied since November, 1895. Mr. Bedding has had this step in contemplation for a considerable time, and has taken it in order that he might devote himself to other journalistic work with which he is identifying himself. Notwithstanding Mr. Bedding's retirement, we understand that his interest in photography will not cease.

PROCESS.—A small exhibition of students' work will be open free from Wednesday, December 28, to Saturday, December 31 (inclusive), between 10 a.m. and 5 p.m., at the London County School of Photo-engraving and Lithography, 6, Bolt-court, Fleet Street, E.C. (The entrance to Bolt Court is between 151 and 152, Fleet Street.) On January 26 Mr. A. G. Cooke will lecture at Bolt Court on "The Light and Power of Modern Illustration—Electricity." Admission to this lecture, which is one of a series, dealing with illustration and process work, is free on application to the Principal.

THE Liverpool Coroner last week held an inquest concerning the death of John Monroe, aged nineteen, an apprentice plumber. For three months Monroe had been experimenting in connection with an invention in the shape of a miniature gas-maker, which could be installed in a small cottage, and could manufacture gas for consumption on the premises. Monroe had obtained the gas from a mixture of water and carbide of calcium: He had constructed a small gasometer at the rear of his father's house. On Saturday the father heard an explosion in the yard, and found his son lying insensible on the ground, bleeding from the head, and injured in various parts of the body. He died without regaining consciousness. Mr. C. R. Bellamy, Liverpool Corporation Tramways manager, explained that the apparatus which the deceased had prepared was very crude, and any test made with it was necessarily attended with danger. Scores of deaths had resulted from similar experiments. Probably deceased had mixed an amount of carbide of calcium out of proportion to the holding capacity of the gasometer. An escape would follow, and if there was any light in the neighbourhood a forcible explosion was bound to result. A verdict of Accidental Death was returned.

CEMENTED OR UNCEMENTED LENSES.

SOME of the earliest of the useful photographic objectives, and which may practically be considered to be typical of certain classes of modern lenses, were distinguished by the introduction of air spaces or air lenses, the Petzval portrait lens being one that will at once recur to the mind of every one. For some years the correction of aberrations was, however, effected, partially or completely, by an increase in the number of the individual lens elements in each cemented combination, and four and five lens combinations were quite common. Then came a revulsion, as it were, and a reduction in the number of lenses and the introduction of air lenses, till we have reached the simple separate four lens construction, with air lenses of calculated form and a total absence of any cemented surfaces whatever.

To the theorist at once occurs the question as to whether there is not a great loss of light by the thus necessary multiplication of reflecting surfaces, because it is well known that perfect refraction without reflection is difficult, nay, impossible, of attainment, and therefore the more we increase the number of refractive surfaces so much the more do we increase the reflective surfaces. Assuming on the other hand that the refractive surfaces are cemented together, there is no loss by reflection, but if the thickness of the glass is increased, or, what comes to the same thing, the number of the glasses and cementing surfaces be increased, then we must have a corresponding increase in the absorption of light by the increased glass mass, and this, while visually undetectable, may play no important role when photographic action is taken into consideration.

In the summer of last year M. Cousin read a paper before the French Society, in which he estimated the loss by reflection from the multiplication of surfaces as high as 40-60 per cent. of the incident light under certain conditions; this was reported in our columns at the time, but later the statement was much disputed.

Recently at a meeting of one of the Frankfort photographic societies this topic cropped up, and finally a circular letter was sent to the leading opticians asking which was the better lens of the two (a) the newer anastigmats with separate lenses, or (b) those with cemented lenses; further, how did the two types of lenses compare one with the other as regards light efficiency with equal apertures, taking into consideration the strong reflections of the former and the absorption of light by the cement and the increased thickness of glass in the latter. The answers to these questions appear in the current month's issue of the "Photographische Correspondenz," and are not without general interest.

Dr. Hans Harting, of Voigtländer and Sons, is of an opinion that the difference between the uncemented surface and cemented surfaces is practically negligible, but that naturally there is a limit, and that the number of elements in a combination must be taken into consideration, and the use of two four lens systems is accompanied by considerable absorption of actinic light. Far more dangerous, he says, however, is the non-correction for coma, and he states that an objective free from coma permits, on account of the more complete combination of the rays and greater brilliancy, a marked shortening of the exposure in comparison to other lenses which possess this fault.

Goerz, of Berlin-Friedenau, believes that for the majority of "amateurs" an objective with cemented lenses of an aperture of about F7 was the most suitable, but gave as his reasons the easier cleaning of the surfaces and the considerably less chance of the scratching of the surfaces, and considered that with equal ratio aperture lenses possessed equal light efficiency, and that the loss by absorption of the cemented surfaces was equal to that caused by the more repeated reflection from the free surfaces.

Zeiss, of Jena, through Dr. Rudolph, says that the question cannot be answered as it stands, and that individual cemented and uncemented systems must be compared. In any case, it may be said that the correction of spherical aberration—which produces increasing indistinctness in the image in the neighbourhood of the axis, when the aperture is increased in size—is generally to be easier effected with the other corrections in uncemented than cemented systems. With regard to the question as to the comparison of the light efficiency between cemented and uncemented objectives with equal ratio aperture, it is, he says, practically the same, or the question is of no moment; "with objectives of short focus the loss by repeated reflection from uncemented surfaces is a few per cent. greater than in cemented; with large objectives the ratio may be unfavourable to the cemented lenses. This is due to the fact that generally with cemented objectives a relatively great lens thickness is necessary, so that finally the loss by absorption, which naturally increases with the amount of the lens thickness can surpass the loss by reflection, which is not dependent on the size of the lenses. In any case it may be said that the small difference per cent. with lenses of equal ratio aperture is not of importance."

Steinheil, of Munich, considers it extremely difficult to obtain two lenses to compare, as for certain photometric work two objectives of equal ratio aperture, of an equal number of lenses, of equally thick lenses, of the same kind of glass, and of the same smelting, should be compared to obtain results of any value as regards the answering of the questions. For the practical photographer it would be advantageous to make clear for what purpose the lens is most suitable. For outdoor work an objective with cemented lenses is to be preferred to one with uncemented lenses, as with the latter there is far greater danger of reflex images, whilst on the other hand the uncemented system has the advantage when projection work is in question, and the lens is subjected to the action of heat, as with cemented surfaces they may be easily damaged. In the studio with diffuse light the separate lens systems may be used without fear. A real decision as to which is the better type of lens Steinheil considers it not possible to give.

Martin, of Rathenow, of the Optische Anstalt, previously known as Busch, combats Martin's views, and considers that as regards reflection the loss of efficiency is about 10 per cent. more with a triple lens than with a double lens, and again about 10 per cent. more for a quadruple than a triple lens. As regards the loss by absorption, Herr Martin considers that it cannot be neglected, particularly when five, six, eight, or ten lenses are used. The important point to be considered, however, is the applicability of the lens, as defined by Steinheil, and last, but not least, its price.

SOME SEASONABLE HINTS.

VARNISHING, important as it is in itself, is almost equally valuable on account of the manipulative facility which much practice confers. If a negative can be varnished cleanly and evenly, the worker will find no difficulty in coating plates for any purpose. The value of this will become apparent as the photographer progresses. If experiments with wet collodion are conducted, the manipulations resemble varnishing minus the preliminary heating. Collodionising temporary supports for carbon, either matt or polished, substratum for carbon transparencies, sensitising for the dust-on process, all are similar to varnishing. We could give a list of other processes which require glasses to be hand-coated, but the above will suffice to show what a valuable asset is a little skill acquired in such a necessary, useful, and yet cheap process as negative varnishing.

Porcelain pans are constantly being recommended by the photographic press for boiling solutions. It requires very little advanced work to demonstrate the fact that such a pan should be found in any well-equipped workroom.

In any process requiring boiling, as with all other photographic processes, absolute cleanliness is an essential. A new enamel iron pan may act for a time, but cannot be compared to the proper article. Moreover, they have the disadvantage of heating up too suddenly. The correct thing is really a pan within a pan, the space between being filled with water. The inner pan is thus practically heated in a water bath, the temperature rising gradually.

Such a pan can be used for heating a great number of things. Among the more common may be mentioned: the developer in winter, bichromated gelatine substratum for lantern slides and transparencies, sizing for home-salted and gum bichromate papers, and for gelatine emulsions of any description. The price paid for all this is not much. My pan was sold as an invalid's food pan. It holds one pint, and costs 3s. 6d.

Printing Frames.—Be careful when buying printing frames. A cheap printing frame is a snare and a delusion. They are nearly always, even if not badly made in other respects, too big for the negative. We have tried all makes, but find nothing to beat the old-fashioned style. Three-quarter-view frames are useful at times, but do not appear to hold paper in such close contact with negative as the ordinary kind.

The backing cloth placed between back and negative should, wherever possible, be thick and soft. We use good pliable felt for print-out papers. For platinotypes and carbon (the latter is as susceptible to damp as the former) indiarubber cloth in the small sizes and American cloth with felt in large sizes are found very handy.

When piling frames one above the other see that all the frames are of one size; a smaller frame between two larger may press on and break the bottom negative.

When choosing a frame see that the backs will lay perfectly flat. With many the join is slightly lower than the ends and presses more on the negative. All backs should have about 1-16 in. space between the two halves. We have had quite an epidemic of breakages with new frames when the hinges have drawn the halves too close together. A frame with solid back, i.e., in one piece, is frequently recommended for papers judged by actinometer. We do not agree with this, as the papers frequently curl, and it is very difficult to get the back on properly, even if it be in two halves.

There have been a great many articles written on print and mount trimming, but none seem to have recognised the very best tool for getting correct rectangularity. Most go in for the clumsy T-square and others the set square, which is seldom large enough for anything over half-plate. The very best thing in our opinion is known as the "Practical" cutting shape. I admit that the common or garden glass shape is of no use

for modern methods of trimming; but this is not a common shape. With it any size print (less than the shape) can be cut with perfect accuracy. This is achieved by the ground-glass face being crossed at intervals of half an inch with transparent lines. These lines being parallel to the sides and at right angles to one another, it is perfectly easy to get any four lines rectangular.

Dark-room Waste-pipe Stoppages.—We have hit on rather a good way to clean out the waste-pipe of a sink which happens to be choked in any way. The pipe should not be bigger than 1 in. in diameter. Water-pressure is used to remove the obstacle and is much handier, and can go into more intricate curves than the usual cane. As most of our readers will have experienced the joys of a flooded dark-room sink, we will describe the method. The only apparatus necessary is a short length of stout indiarubber pipe which can be fixed on to the tap. Any description of nozzle will do for this. The other end is merely placed into the plug hole and tied round with a cloth. This cloth is fixed tight round tube and rests on bottom of sink. When this is done, press the rag down as hard as you can and turn the tap full on. The pressure will probably force a little water into sink for a moment or two, but if you keep the cloth tight round the tube and press it well down the pressure of the water should remove the obstacle in all but very stubborn cases in a moment or two.

Cleaning Opals.—Many a time does a carbon on opal outlive its popularity, making the owner only too glad to use the support for something else. Carbons are extremely difficult to remove, however, so the following hint may be of service. The only way found at all efficacious is to pickle the opals for a day or two in dilute nitric acid, say, 1 oz. in 20 oz. After this rinse well and scrub off with very hard brush. In very bad cases two opals ground together with sand between usually removes the last trace of film.

Clearing off negatives in large batches is neither clean nor rapid work. The handiest way is to soak for twenty-four hours in water, and then to plunge into hot water containing carbonate of soda.

It is a great waste of time and trouble in carbon work to safe-edge every negative. The better plan is to clean off some wasters, safe-edge these, and place in front of the negative to be printed. Do not be too stingy with the binder; a narrow safe-edge often leads to disaster.

Another useful carbon hint is to mark the wrong side of drawing or etching papers before soaking them, as it is almost impossible to recognise prepared side when wet. The well-known method of testing exposure by printing P.O.P. proof deep is always reliable in any light. But, when printing from paper negatives, printing may have to be postponed for the night, and continued in the morning. In this case do not forget to make allowance for increase in depth during the night. This increase varies considerably, but I usually add six tints, and find it fairly correct.

W. FOSTER BRIGHAM.

THE Hastings and St. Leonards Photographic Society's Exhibition will be held from January 11 to 13, 1905. There will be a special class for pictures rejected at this year's Salon and Royal. Seven open classes. Entries close January 2, 1905. Prospectus and entry forms from the Secretary, Fred Judge, 21a, Wellington Place, Hastings.

It is with pleasure we have to announce that the Duchess of Portland has kindly promised to open the popular Grantham Industrial and Fine Art Exhibition on January 18, an announcement which will give universal satisfaction in the neighbourhood. The visit of the Duchess of Portland on January 18 and the Duchess of Sutherland on January 19 will help considerably to make the exhibition a success. The prizes will be distributed by Lady Marjorie Manners on Friday, January 20.

THE PRACTICAL PERFORMANCE OF TRI-COLOUR FILTERS.

III.

While many think there are valid theoretical reasons for the use of curve filters, they must suppose at the same time perfect photographic plates with unlimited power to render gradation, that is to say, a straight line law for photographic action, which it can never follow, the plate to be perfectly exposed and the printing to be done in perfect inks, but the spectrum reproductions with graded exposures prove conclusively that the action of a photographic plate is such that they cannot be made to follow any definite set of curves, such have been suggested in various hypotheses of tri-colour reproduction. This result was to be expected, if the facts are taken into account when theorising, for only in the case of very slow plates is there any proportionality between the light stimulus and the opacity produced in the negative, and in this case only over a small part of the total range of action. Now slow plates are useless in all cases where an extended scale of gradation has to be rendered, as in an oil painting, for this purpose fast plates have to be employed, and with these there is scarcely any region of proportionality at all, as was proved by Messrs. Hurter and Driffield. Another consideration is that such curve filters, even if possible, would be difficult to make, and we think we are safe in assuming never have yet been made (although approximations have), and if they were they would certainly break down in use. The fact that the exposure on the lower slopes of a curve will often fall below the minimum of the effective stimulus (so-called photographic inertia) causes these to be lost entirely, restricting the recorded regions to the higher parts of the curve. On the other hand, in practice it is found they are not necessary, since the spectrum can be tolerably imitated, and all natural colours fairly well reproduced by using filters and plates recording three even bands, the blue-violet extending to wave length 5,000, the green record extending from wave length 4,600 to 6,000, and the red record extending from wave length 5,800 to the end. The ultra-violet should be cut out, since it can have no possible utility, and does in certain cases exercise a degrading effect on some colours. Such filters appear to us to give the best results throughout a range of contrast within the limits of the plate.

The influence of the sensitiveness and the capacity for rendering gradation of the plates is very great, thus no plate records the extreme red, and with some so-called panchromatic plates used for three-colour, even a light red is reproduced more or less as black. However, in the case of pinachrome bathed plates and collodion emulsion dyed with ethyl violet, the red is recorded much farther than usual. With regard to gradation it is obvious that with a plate having a very steep range, the light tones of the picture will be fully exposed long before the deeper ones have had time to fully impress themselves, and this becomes of the utmost importance where the complementary colours are strongly contrasted in the opposite way to the record desired, thus a dark green and light crimson, a dark blue and pale yellow, a deep orange and pale blue; in each of these pairs the dark colours should be more or less fully recorded and the light ones more or less stopped, but with normal filters and normal exposures on a plate having steep gradation this is not done, as we have proved in the case of wet collodion and collodion emulsion.

The ideal conditions of filter and plate would be that colours should always record evenly throughout, even with the longest exposure, not extending beyond the limits laid down, and even with the shortest going all the way, though the deposit were less opaque. It should not be forgotten that in an ideal three-colour negative the selected colours should be at least as well recorded as white itself, because if there is any less opacity,

then it means the subsequent printing there of some part of the antagonistic complementary. Thus, if a white and a pure green do not record equally well through the green filter, then it means, when printing, the degradation of the green by the addition of some crimson ink because more crimson ink will print on the green than on the white. Needless to say this is not attained in practice, and a possible compromise in the case of subjects having complementary colours, widely antagonistic in contrast, may be found in narrow-banded filters, correct in the principal position. The greens are nearly always the trouble, chiefly because they are generally of low luminosity and do not get recorded on the plate before the complementary colours (minus green) are recorded. Thus one has seen a girl with pink cheeks in a green dress, the cheeks reproduce white, while the dress is nearer brown than green, owing to the large amount of red printed over the yellow and blue.

To discover the suitability of the filters, it is not necessary to go to the length of reproducing the spectrum in half-tone in the way we have done, as a simple examination of the spectrum negatives, made in the same ratio of exposure as camera exposures, after a little experience will at once enable one to determine if the records are correct or not, and from them to prophesy with practical certainty what colour will reproduce well and what badly. Nor need the spectra be reproduced in order to determine whether inks are suitable or not, for after some experience the mere printing of a solid patch, singly, in pairs, and all superposed, will indicate at once whether they are suitable or not. We conclude that:—

1. It is not possible nor is it desirable for any filter and plate to follow either the colour sensation, colour mixture, or certain other calculated curves.
2. The effect of using plates, having maxima with broad banded weak filters, is to cause a degradation of any pure colour occurring in the band of insensibility, therefore plates showing gaps in the spectrum record should not be used for the green negative.
3. Ultra-violet should not be recorded, as it will exercise a disturbing effect where it is reflected by colours other than blues and violets, as is the case with some browns, scarlets, and yellows, these reproducing with a distinct bluish tint.
4. As much red should be recorded as possible; ethyl violet in collodion emulsion, or pinachrome bathed dry plates, at present give the best record of red.
5. There should be no unrecorded gaps in the visible spectrum, for while these may not be important, for certain mixed colours of pale tints, they are fatal to correct rendering of colours whose spectra do not extend beyond the gap.
6. We think that we have proved that the filter records should be even, end abruptly, and overlap each other as follows: the blue-violet and the green should overlap from 4,600 as far as 5,000, and the red and green should overlap from 5,800 to 6,000.*

A. J. NEWTON AND A. J. BULL.

LATE last Wednesday night the shop tenanted by the London Photographic Co., Taff Street, Pontypridd, was completely gutted by fire.

At a meeting held last week the Kettering Camera Club was successfully launched on what we hope will be a prosperous and lengthy voyage. It is intended to have senior, junior, and honorary members, and Mr. Claypole was appointed hon. sec.

* NOTE.—This latter point has been stated before the Optical Society in December of last year, but it has been found necessary in practice to extend the overlap of the green and blue-violet records into the blue.

STOCKTAKING AND RESOLUTIONS.

BY AN OCCASIONAL CORRESPONDENT.

"First and last I have spent three hundred pounds in stock." So said a proud professional photographer to me as he showed me over his studio. "Why, I've three cameras, and one of them cost me £20."

I learnt that only two of the cameras were ever used—the third one was altogether antiquated and useless. But all three of them stood in the studio, and were likely to stand.

We had been talking about the value of his "tools of trade" during a chat about stocktaking. "Why should I take stock?" he asked. "I know that three hundred pounds of good money stands there, and I don't pay more than its worth for anything. I know what I've got. Why should I bother about turning the place upside down?"

Probably many photographers are in the position of my friend; not knowing where they stand, simply because they are so sure that they do know. The eve of a new year is the time-honoured date on which business men endeavour to learn exactly "where they are," and it is a good date for calmly thinking about business. Give to this matter a few minutes of the time supposed to be devoted to new year resolves and resolutions. Only remember that in this case the resolution must be put into action at once—at the close of the year—not during the coming one.

The actual work of making a list of the stock, etc., can be done in one or two evenings. The figuring may come later, and this figuring it is that tries a man's self honesty. One man will write himself down worth £200; another man will take the same assets and make himself worth a thousand. And yet both are honest men, and are simply trying to learn the truth for their own information.

Take those stacks of negatives—perhaps 10,000 of them. What are they worth? Some of them may be worth pounds. Granted; all know of the family who suddenly discover that a negative of grandma is in existence—now that the lady herself is not. They at once rush to order half-a-dozen of the best enlargements. Suppose the negatives are worth only one shilling each (most absurd suggestion), the whole stock is worth £500. There is a certain amount of speculation in keeping old negatives. I know, but an approximate idea of their value can be obtained by reckoning how much income has been derived during the year from all negatives more than twelve months old; £25 is 5 per cent. on £500. Have the old negatives paid this 5 per cent. on their value, plus the time and material absorbed by these re-orders? If not, they are estimated too high at one shilling each; but whether they are worth a penny or a pound, the time spent in discovering that worth is time well spent.

There is a stock of platinum paper which has spoilt. Ought it to be put down as an asset at the price it was invoiced and paid for, or ought it to be left out of the balance-sheet and put into the dust-bin—honestly now?

Then the backgrounds. Surely they are not worth what was paid for them, for one or two are never used, and others are much worn. The cameras, perhaps, which are in use are as good (for practical work, not in appearance) as when bought. They may not wear out in the present generation, but they may be superseded, like the idle one in the corner. In estimating their value, a certain percentage should be written off each year. The same on the other apparatus and accessories—even, in most cases, on the lenses.

Many a photographer who is doing a prosperous business buys more material at a time than he needs. The traveller who calls gets a bigger order than the firm would have got had the order gone by post. And there are photographers (or assistants) in existence who put the fresh stock on the front of the shelf and push the old stock back. There are—well, perhaps "skeletons"

is hardly the word—in many a photographer's store-room. The man who has not taken stock for years may find a revelation if he goes into every corner and lists everything.

The goodwill of a business is a curious quantity. I suppose it is what it will fetch in case the business is sold, and he is a very prescient man who can say what the price will be. I will not attempt it.

It is a simple matter, except in the case of those who give long and dubious credit, to put down on paper the money due and owing. And it is easy to put down the value of paper, plates, etc., in current use. They are worth invoice price. But on the more permanent apparatus, and such illusive things as goodwill and stock negatives, an honest approximation of value is often far from easy.

Once a stock sheet is made and digested, it should be put in a safe place. A series of them are mighty valuable when you come to sell a going concern. And they may even—I hope they will not—be useful in the unfortunate event of a fire. Of course, I am supposing that the fire premiums are promptly paid.

The new year is said to be a great time for the manufacture of paving stones for the nether regions. But soundly thought out resolutions are good things in spite of proverbs. A sort of mental stocktaking of a past year is no bad venture; particularly where the year has been a poor one. Often there are sufficient causes for all the depression which there has been, and always there are plenty of reasons to be found for it. But, unfortunately, the discovery of the causes does not remove them, nor prevent their recurrence in the future. And the causes are very real hard facts. Many a wide-awake, hard-working man feels the shoe pinch at one time or another, and he sets about trying to ease the shoe. But to return to the mental stock-taking.

What are the causes of the depression? Perhaps money has been scarce all round, and people have not had it to spend on what, after all, is scarcely one of the necessities of life. It may be that there is really undue competition; two fighting for support where there is business for only one. We have had a sufficiency of the first cause of late; and the second cause exists in many places. How are they to be remedied? There is one mistake which is responsible for much of the failing trade—the mistake of sitting down and waiting for work. If trade does not seek the photographer, he must seek the trade. How is he to do it; by advertising, by circular, by personal canvass? The two first cost money; the latter is impracticable in many cases. And neither advertising nor circular—both of which are sound investments when judiciously done—will draw or hold trade if the work of the studio does not back them up. Is the work up to a good standard, or is it all turned out by rote—"three styles of pose and two styles of printing"? Are the mounts and the styles of printing up to date? Is the reception-room a place to pleasantly impress visitors? Are the dressing-room and the studio clean and tidy? Is the show-case always displaying some new thing through a clean glass; or is it untended for weeks? Minor things, perhaps, but many minor things combine to make a determining factor. I am not on a hunt for reasons; I am only stating one or two not uncommon ones—in failing businesses.

They are causes which can be remedied without cash outlay, and that is why I refer to them. If the photographer will make a list of the things which may advantageously be done during the waits for sitters, and devote some of his "waste" time to doing them, he may find that his new year resolutions bring paying results.

DETECTED by Finger-prints.—At the Clerkenwell Sessions, Walter Rose, 22, and Henry Margrie, 25, were sentenced to twelve and six months' hard labour respectively for burglary at Poplar. They were arrested after finger-prints left by Rose had been photographed.

PHOTOGRAPHIC PERIODICALS IN THE PATENT OFFICE LIBRARY.

THE following list of the periodicals in the library of the Patent Office in Southampton Buildings, London, E.C., is reprinted here from the official catalogue just issued, as many students of photographic literature will be glad to have at hand a memorandum of the journals which they are at liberty to consult. The Patent Office library is open to the public, and the shelf-arrangement of the volumes is such that a given subject can be traced more easily and rapidly than in any reference library, English or foreign, with which we are acquainted.

THE ACTION OF METALS ON THE PHOTOGRAPHIC PLATE.

[Abstract of a paper by Professor G. W. A. Kahlbaum before the Naturforschender Gesellschaft of Basle.]

IN the course of some experiments on the distillation of metals in vacuo, the author was led to investigate the effect of different metals on the photographic plate when there is absence of contact between the metal and the film of emulsion. The conditions of the experiment were as follows:—A photographic plate was laid in a shallow case of black paper, covered with a strip of paraffin paper, and a cardboard frame, about 1.5 or 2 millimetres in thickness, laid upon this. Next came four strips of aluminium, iron, zinc, and lead, which were supported in the middle by a little cylinder of paper.

On these was laid a second piece of paraffin paper, next another cardboard frame of the same dimensions as the first, and finally another sensitive plate, but with the film side turned away from the metals. The case was closed, and the whole laid in the horizontal position for five days in a perfectly dark place. On development it was discovered that there was a very strong, well-defined image of the four metals on the lower plate, whilst the upper plate indicated only a weak action from the zinc and a still less, scarcely recognisable, effect from the aluminium. The metals had been previously examined for their transparency to Röntgen rays. Other plates which had not been exposed to Röntgen rays, and others which had lain for four days exposed to radium, were found to exhibit the same marked differences in their action on the upper and lower films, except that the action of the unexposed zinc and aluminium was more distinct in the case of the uppermost plate. On these plates being subjected to Röntgen rays for some time the images ceased to appear on the upper plate. These experiments, which were repeated a number of times with the same result, seemed to suggest that the phenomenon was connected with an emanation from the plates, which was subject to the action of gravity.

On making the experiment with the metals and sensitive plates in a vertical position the action was the same on each plate, but very much weakened in both cases; whilst on placing a strip of lead diagonally between two photographic plates a weak image, distorted into parabolic shape, was produced. An experiment with plates, 3 and 2 cm., arranged staircase fashion above and below a zinc plate, gave images the intensity of which varied with the distance of the film of emulsion from the zinc, but also showed a difference between the upper and lower plates to such an extent, the zinc furthest from the lower plate produced a greater effect than that nearest to the upper plate. The deposits of silver were measured with Marten's

apparatus. If the zinc plates were kept on a centrifugal in motion during the exposure of forty hours two images were obtained on each plate, but the difference between upper and lower was still recognisable. The emanation, therefore, appears able to pass through glass. The temperature and humidity of the air appear to have great effect on the intensity of the action, which has been observed so far in the cases of aluminium, iron, nickel, copper, zinc, lead, and uranium. Of these, iron, nickel, copper, and lead were the only ones to give distinct images on the lower plate. Aluminium gave a very weak image on the upper plate, and so did zinc and uranium.

THE METRIC WEIGHTS AND MEASURES.

With reference to our note on this point last week, we reprint from our contemporary, the "Pharmaceutical Journal," the following comment on the three new designations which will be read with interest:—

"The inconvenience caused by the lack of any officially recognised subdivision of the litre, smaller than its one-thousandth part, and the consequent difficulty of expressing doses of potent liquids in convenient metric quantities, should shortly cease to exist, as we understand that the three new designations—mil, decimil, and centimil—are to be inserted in a reprint of the Board of Trade Regulations dealing with inspectors' metric standards.

"The new apothecaries measure will, presumably, be as follows:—

METRIC APOTHECARIES MEASURE.

1 Centimil (1/100th Millilitre).....	=	0.1689 Minims.
1 Decimil (1/10th Millilitre).....	=	1.6894 Minims.
1 Mil or Millilitre (1/1000th Litre).....	=	{ 16.8941 Minims. or 0.2816 Fl. Drachm
1 Centilitre (1/100th Litre).....	=	{ 2.8157 Fl. Drachms, or 0.3519 Fl. Ounce.
1 Decilitre (1/10th Litre).....	=	3.5196 Fl. Ounces.
1 Litre.....	=	1.7598 Pints.

The minim is equal to nearly six centimils, the fluid drachm to rather more than three and a-half mils, and the fluid ounce to nearly three centilitres, thus:—

1 Minim.....	=	5.9192 Centimils.
1 Fluid Drachm (60 Minims).....	=	3.5515 Mils.
1 Fluid Ounce (8 Fluid Drachms).....	=	2.8412 Centilitres.
1 Pint (20 Fluid Ounces).....	=	0.5682 Litre.
1 Gallon (8 Pints or 160 Fluid Ounces).....	=	4.5459 Litres.

"While referring to this subject, it may be stated that a decimetre scale, which is graduated to one hundred parts, and can be obtained from the Decimal Association for a few pence, will be found useful for making metric measures of length more familiar. The scale is one millimetre thick, one centimetre wide, and one decimetre long; its volume is one cubic centimetre, and its weight in grammes is the specific gravity."

A MAGIC Postcard.—So many crimes are committed in the great name of advertisement, that (according to the "Bromide Monthly") one more does not appreciably affect the iniquitous total. But it has been reserved for an inventor, Joseph Rieder, to perpetrate a scheme against those who would escape from the snare of the advertiser. Explained in a word or two the insidious plot is as follows:—The victim will receive a postcard addressed as usual, but blank on the picture side. Out of innocent curiosity he will keep the card. He will soon see signs of a semi-latent picture. Further exposure to daylight will develop an infant reared on somebody's food or of a young person in somebody's corsets. By these means it is hoped to fix indelibly the nature of these articles upon the recipient's memory.

A GELATINE DAGUERRETYPE PROCESS.

[A Paper from the "Photo-Beacon."]

The production of photographs upon a highly polished silver surface, by the process originated by Daguerre, is difficult to obtain unless an apartment is specially fitted to carry out the various operations successfully. An excellent imitation of the Daguerreotype can be produced by the transfer of a gelatine film after it has been properly treated and its colour changed so that it has the colour which closely resembles the deposit upon a Daguerreotype plate. This can be accomplished in a manner that is practicable in the workrooms of the modern photographer, so that there is no necessity for special rooms to sensitise the silvered plate in, nor a special room for the development with mercurial vapour; all that is necessary is to prepare a special developer and a stripping solution, one that can be relied upon at all times for a sure removal of the film from the original glass plate.

The gelatine plates best suited for this class of work are those that work slowly, so as to give very clear and transparent shadows. The silvered plate can be procured in sizes required from a maker of reflector plate. This consists of a sheet of copper which has been coated with pure silver upon one side and polished, but the surface does not possess the requisite polish for the purpose required, so it will be necessary, after the plate has been cut to the various sizes, to have them planished, that is, to have them carefully flattened, and polished to a high degree at an electro-plating establishment. They must then be carefully packed so that the surface will not become scratched, with a soft layer of wadding between each. The following solutions must be prepared and kept on hand ready for use:—

DEVELOPER.

Distilled water (warm).....	18 ounces.
Metol.....	10 grains.
Hydroquinone.....	30 grains.
Sulphite of soda.....	220 grains.
Carbonate of soda.....	160 grains.
Potassium bromide.....	3 grains.

Dissolve the chemicals in the order given. As soon as the liquid is cold it must be filtered through absorbent cotton into a clean bottle.

The fixing solution may be made up as follows:—

Water.....	45 ounces.
Hyposulphite of soda.....	1 pound.
Sulphite of soda.....	1 ounce.

Dissolve the above and add thereto the following solution:—

Water.....	15 ounces.
Chrome alum.....	1 ounce.
Sulphuric acid.....	1 dram.

The chrome alum should be powdered and dissolved in warm water. When the two solutions are mixed, they should be filtered and the fixing bath kept away from dust and dirt. A glass or porcelain dipping bath is best suited for holding the fixing solution. All the solutions must be kept very clean, otherwise all specks and marks will show up prominently when the image is transferred. The mercury solution is made up as follows:—

Distilled water.....	15 ounces.
Bichloride of mercury.....	100 grains.
Bromide of potassium.....	100 grains.

The distilled water must be brought to boiling point in a glass flask, together with the above salts. When all is dissolved, add fifteen ounces more of cold, distilled water, then filter the solution. With these solutions ready, the exposure may be made upon a slow-working gelatine plate. The exposure must not be so long as for a full-bodied negative. As soon as it has been made, say upon a 4 by 5 plate, proceed to develop with the developer above given. It will be seen that the image comes up fairly well, but presents a weak appearance. This is just what is required. Do not attempt to force the development. If this is attempted the shadows will become degraded instead of remaining clear. Development being complete, wash the plate well and fix in the solution described. Allow the plate to remain in the fixing solution for some time after fixation is complete; then take out the plate, wash well for at least half an

hour in running water, then allow it to dry. As soon as the plate is thoroughly dry, place it in a clean tray and pour upon it enough of the mercury solution to cover it well. Rock the tray so as to expose the surface of the plate to fresh action of the solution. Whenever the film appears white, remove the plate and wash it well. Return the mercury solution to the bottle for future use, as this solution can be used over and over again. Place the plate once more aside to dry. When the plate has become thoroughly dry, the operation of removing the film and its transfer may be taken in hand.

Take one of the polished, silvered plates and clean it in the following manner:—Prepare a solution of lye by dissolving four ounces of potash lye in twenty ounces of warm water (this solution must always be used in a warm condition), hold the plate to be cleaned at one corner with a pair of pliers, then dip it into the warm lye and wipe over its surface the solution with a piece of absorbent cotton pressed into a six-inch length of vulcanised rubber tube so as to form a miniature mop. These precautions are necessary to prevent the lye from coming into contact with the fingers, because it might injure them and cause soreness. As soon as the plate has been carefully mopped, it may be washed under the tap: If the water runs over the plate so as to leave no greasy streaks, and remains upon the plate uniformly, the plate is then perfectly clean. It must now be coated with the following mixture:—

Gelatine (hard)	20 grains.
Distilled water	2 ounces.
White sugar	10 grains.

To which five drops of chrome alum solution have been added, compound of fifteen grains of chrome alum to one ounce of water. Filter this while still warm through two thicknesses of cheesecloth, and flow over the wetted surface of the silvered plate. Pour this gelatine mixture upon the plate two or three times, returning the superfluous solution to the glass tumbler from which it was poured, always allowing the corner of the plate to touch the side of the tumbler so as to prevent the formation of air bubbles. Set the plate to stand aside away from dust to dry. As soon as it is dry it is ready for use. Now make up the following solutions for stripping the gelatine film from the plate. These solutions will keep in good working condition for several weeks if kept separately:—

A.	
Fluoride of sodium	60 grains.
Water	5 ounces.
B.	
Citric acid	120 grains.
Water	5 ounces.

Place the gelatinised, silvered plate into a tray of clean water to soak for five or ten minutes, then place it into a small tray of distilled water and it is now ready to receive the gelatine film.

Take two ounces A and mix with two ounces of B; immerse the plate containing the image in this mixture, rocking the tray backward and forward and sideways. In the course of two or three minutes the film will be seen to wrinkle at the edges. As soon as this takes place the film may be easily lifted clear off the plate with the forefingers and thumbs of each hand. It must then be placed in a tray of clean water. This is to wash off the excess of stripping liquid. Lift the film from this tray and place it into the tray containing the silvered plate, then with the forefingers and thumbs of each hand raise the plate and film together so that the water runs from between them. The plate must now be laid flat, say upon the top or bottom of a glass tumbler, and the film carefully adjusted by a soft camel's-hair brush. When in proper position it must be left in a horizontal position to dry.

It will be observed that the film has become enlarged somewhat by the operation, so that a 5 by 4 film will fit a 6 by 5 silvered plate. This slight enlarging of the film is in one way an advantage, because in stretching it makes the shadows thinner and more transparent so that the bright silver surface shows through it better. When the transferred film has become dry and the operation has been carried out with care and cleanliness, the plate will present an excellent imitation of the Daguerreotype, and, when mounted in a suitable frame and tinted with a few light touches of dry powder colours, the effect is that of a tinted Daguerreotype, and is scarcely distinguishable from one of these beautiful productions.

It will be found absolutely necessary to have all the solutions perfectly clean, and the last trays *must* be filled with distilled water, because ordinary water contains such impurities as lime and organic matter, which, in drying down upon a bright metal surface, will always show up in a very pronounced manner, and thus spoil what would be in every other respect an excellent picture.

The gelatine solution used to form a substratum upon the silvered plate may be made in quantities of a pint or more, as it will keep for several weeks, especially if one ounce of alcohol is added to each pint of mixture, and well incorporated by stirring when the mixture is hot.

The fluoride of sodium and citric acid mixture must be discarded after it has been mixed for an hour; several films may be detached with the same solution during an hour, the stripping effect holding good for this time.

This stripping mixture is also very good and useful in stripping a film from a cracked negative, providing the gelatine film is not broken. It can then be transferred to a clean glass plate, which should be of larger dimensions than the negative, so as to give working space, the plate then being cut down to the original size. The developing solution given herewith can be used several times over; in fact, after it has been used two or three times the pictures produced are of a good quality for the process described. In the process of development, do not try to force the image; let it come up weak and thin, because a picture that has been forced in any way will not give the desired result. It must be borne in mind that the shadows must be as transparent as possible, for only thus is the Daguerreotype effect secured. If the shadows should be at all muddy, the beautiful quality and effect so desirable in a picture of this kind are entirely lost. Plates of highly-polished copper may be also used for transferring the image upon, and this gives an effect exactly like an electrotype made from a Daguerreotype, in which a bright copper surface replaces that of silver.

If dry powder colours are used for the tinting, any excess of colour can be easily brushed off the surface with a clean, dry pencil or camel's-hair brush, and the colours fixed upon the plate in a very stable manner by simply breathing upon the surface of the picture after the colours have been applied, the moisture contained in the breath supplying all the damping effect that is needed to make the colours stick to the semi-hardened gelatine film.

The transfer of these films has not been satisfactory when attached to aluminium, as the polished surface of aluminium gives a white reflection, while that of silver is the reverse in effect. The clear parts of the image, such as the hair, a black coat and a velvet collar, are all represented as black when viewed at a suitable angle, as exemplified in the Daguerreotype. As to the varnishing of these pictures, that will prove to be a matter of taste. All ordinary varnishes do give a slight tinge of colour to the film, and consequently are not to be recommended. There is a varnish that can be used, which is prepared by dissolving celluloid in amyl acetate, and usually sold under the various names of celluloid collodion, crystalline varnish and albaline and a special liquid which is called "thinner," to thin down the thick, viscous collodion. Judging by the odour of this last liquid, it appears to be amyl alcohol. Albaline, when thinned down, forms an excellent varnish, perfectly transparent when dry, as well as protecting the film from the effects of moisture, alkalis, or acids. It may be dried by heat or allowed to dry spontaneously; in either case the result is the same. The cost of the above varnishes is not at all high, and they can be relied upon as a perfect protector of the film.

A. J. JARMAN.

SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.—Messrs. J. T. Ashby, F.R.P.S., H. W. Bennett, F.R.P.S., and Frederick Holley, F.R.P.A., have kindly consented to act as judges at the Sixteenth Annual Exhibition, to be held March 4 to 11, 1905. There are open classes for portraiture, architecture, landscape, lantern slides (sets of four), and stereoscopic slides (sets of four), in which silver and bronze plaques will be awarded at the discretion of the judges. A gold medal will be awarded to the best picture in the open classes. Entry forms will be ready in a few days, and may be obtained from the hon. secretary, Mr. H. Creighton-Beckett, 44, Edith Road, Peckham, S.E., who would also be pleased to hear from any one desiring to join the society.

THE THEORY OF FLUORESCENCE.

[A portion of a paper in the "Physical Review."]

THROUGHOUT the progress of the experiments that have been described in the present paper and in those which precede it we have naturally tried to form some picture of the underlying mechanism of the phenomena studied. It is perhaps needless to say that serious difficulties have been encountered; but although we have not succeeded in forming a wholly satisfactory picture of the molecular processes involved in fluorescence, the considerations stated below have nevertheless led us to the adoption of a working hypothesis regarding the general character of these processes, which has been of considerable assistance.

In attempting to form a theory of fluorescence it is natural to turn to the other, and in some respects simpler cases of luminescence for assistance; for it is difficult to believe that the many resemblances noticeable between luminescence phenomena of different types are merely superficial. In the case of several classes of luminescence phenomena the first steps in the development of a theory have fortunately already been taken. Thermo-luminescence, for example, has been explained as the result of some chemical change in the luminescent substance, during the progress of which the molecules are thrown into such violent vibrations as to bring about the emission of light. Luminescence ceases in such cases when the change has been completed; and some outside stimulus is required, such as that furnished by cathode rays, to restore the substance to the sensitive state. Not only is this explanation of the thermo-luminescence a plausible one, but in several instances conclusive evidence has been found that the assumed change really occurs.

A somewhat similar suggestion has been made by E. Wiedemann in the case of phosphorescence. According to this view some change is produced in the phosphorescent substance by the action of the exciting light, and the gradual restoration of the original condition after the excitation has ceased is accompanied by luminescence. Although it has not yet been possible to determine the exact character of the assumed change, or even to demonstrate by direct tests that such a change occurs, the view suggested by Wiedemann has undoubtedly been an important aid in the more recent study of phosphorescence.

If, as seems not unlikely, the difference between phosphorescence and fluorescence is chiefly one of the duration of luminescence, the hypothesis just stated may be applied to the latter class of phenomena without essential modification, and we may assume that fluorescence is also due to some temporary change in the fluorescent substance. We must assume further that the return to the original condition is almost instantaneous; so that luminescence persists for only an inappreciable time after the removal of the exciting cause. According to this view fluorescence involves two processes: (1) the alteration in the fluorescent substance brought about by the exciting light; (2) the spontaneous return of the modified substance to its original state. These two processes occur simultaneously; and one or both must be accompanied by the emission of light.

This view lends itself readily to an explanation of the increase in absorption that accompanies fluorescence, for it is clear that during the progress of such a change as is here assumed the substance may possess properties that are entirely different from those of the original substance. It is natural also to expect some intimate connection between fluorescence and fluorescence absorption, for the increased absorption during fluorescence is doubtless due, at least in part, to the same molecules or atoms whose vibrations bring about the emission of light. Without more detailed assumptions regarding the nature of the change produced by the exciting light it is not possible to predict the laws of fluorescence absorption, e.g., the dependence of the effect upon wave-length, intensity of fluorescence, etc. But, on the other hand, the experimental study of these laws will afford a firm foundation for the further development of the working hypothesis.

The considerations which make it natural to expect a change in absorption during fluorescence apply equally well to all cases of luminescence in which there is a change in the active substance during excitation and a return to the original state during luminescence. We should therefore expect a change in absorbing power in the case of thermo-luminescence, chemi-luminescence, and phosphorescence. In fact, it seems not improbable that some modification of Wiedemann's original hypothesis may be found to be applicable to all classes of luminescence, and in this case we should

expect every type of luminescence to be accompanied by a change in absorption. So far as we are aware, no experimental study of absorption during luminescence has been undertaken except in the case of fluorescence.

A hypothesis which assumes that luminescence results from some chemical or physical change in the luminescent substance evidently implies not only a change in absorbing power during luminescence, but also temporary alteration in the other properties of the substance. The study of these changes, if such are found to occur, offers a promising means of attacking the general problem. This field of investigation also appears to be practically untouched.

It has generally been assumed, by those who regard Wiedemann's suggested explanation of phosphorescence and thermo-luminescence with favour that the change accompanying luminescence is of a chemical nature. Various suggestions have been made regarding the character of the reactions produced by the exciting light (or other cause), and attempts are not lacking to trace a connection between luminescence and chemical constitution. It appears to us that it is desirable to take into consideration changes of a different kind, which do not involve, necessarily, any chemical action. The simplest change of this kind is dissociation. In cases of photo-luminescence this is just the effect that we should expect the exciting rays to produce. We can scarcely doubt that the absorption of the exciting light is the result of resonance on the part of the molecules or atoms of the active substance, and although the vibrational energy thus imparted to the molecules is rapidly transformed by collisions into translational energy (heat) yet under favourable conditions the molecules might be thrown into such violent oscillation as to be torn apart. Since chemical activity is usually increased by dissociation, chemical changes of the usual kind might occur as a secondary effect. Many instances of increased chemical activity due by the action of light on fluorescent substances might be cited.

If we look upon light as an electromagnetic phenomenon we should expect the vibrations produced by the exciting rays to be such as tend to separate the positive and negative parts of the molecule, and the resulting dissociation would either be of the usual electrolytic type or similar to that produced in a gas by the action of Röntgen rays. In the case of fluorescence the latter type of dissociation seems most probable; but in either case, if the view outlined above is correct, fluorescence should be accompanied by an increase in the electrical conductivity of the fluorescent substance. It was in order to test this conclusion that the experiments described in the third section of this article were begun. A more detailed discussion of the hypothesis outlined above, and of the experimental facts which tend to confirm it, is reserved for a later communication.

E. L. NICHOLS AND ERNEST MERRITT.

SPECTROPHOTOMETRIC STUDY OF SOLUTIONS OF COPPER AND COBALT.

[Abstract of a paper presented at the St. Louis meeting of the Physical Society, and published in the "Physical Review."]

THE effect of dissociation upon the colour of solutions may be studied in two ways—by the photographic or by the spectrophotometric method. The latter has the advantage of quantitative determination of absorption both in strong and in dilute solution. The latter method has been used by a number of observers, who have generally confirmed Ostwald's law, viz.: "That the colour of dilute solutions having a common ion is identical."

The method consists in the study of the absorption of such solutions in the concentrated and dilute form. It occurred to the writer that these solutions could be diluted in another uncoloured solution containing a common ion of great concentration, and thus prevent a large part of the dissociation, or, what is the same thing, repress the dissociation by the principle of mixed electrolytes.

The present experiments are limited to the study of the sulphate, chloride, nitrate, and acetate of copper; and the sulphate, chloride, and nitrate of cobalt. They have been given the usual treatment and have besides been diluted in strong acids corresponding to the negative ion of the salts. The method eliminates the absorption of all components except the one which is studied.

All the copper salts in dilute water solutions have identical absorp-

tion per equivalent in the strong absorption region at the red end of the spectrum. The cobalt salts also give identical absorption in dilute water solutions in the green band. In the more transparent regions, blue and red, the indications are that the cobalts might be identical in great dilution. They are, however, far from it at the dilutions studied. In the regions nominally transparent the copper salts show great divergence in the dilute water solutions, and the indications are for larger divergence with greater dilution. The standard solution of copper sulphate and this solution diluted both in water and acid give identical absorption per equivalent in the red band, i.e., in this region the colour of the ion and molecule are identical. In this same region the nitrate and chloride become relatively more transparent upon dilution.* When diluted in acid they become relatively darker and, if the acid is of adequate strength, even become darker than the original solutions. The acetate shows identical absorption in all solutions, and in the red region the absorption is more than twice that of the sulphate. The three cobalts become relatively more transparent upon dilution. Treating then with acids darkens the dilute solutions of the chlorides and nitrates but makes the sulphate more transparent. Possibly some of the cobalt sulphate was precipitated by the sulphuric acid treatment.

B. E. MOORE.

MODERN PHYSICS IN RELATION TO PHOTOGRAPHIC OPTICS.

THE review of the development of photography in England was not very gratifying, the lecturer stated. Foremost in the fields of theory and practice at different periods, England had allowed herself to be overtaken. George B. Airy had, in studying the camera obscura in 1830, grasped the problems of astigmatism and curvature of field; but his researches remained almost unheeded until Rohr drew attention to them. The early English opticians, on the other hand, to whom photography owed so much, were not mathematicians, and continued to follow empirical rules until the leadership was no longer theirs. William Hamilton gave the complete theory of the formation of images six years after Airy had published his researches, but Finsterwalder and Thiessen had to point out the importance of Hamilton's work, and to make it intelligible to practical British opticians, who then counted few men like Traill Taylor and Chance. In those early days Petzval, in Vienna, was the only man who carried out in practice theoretical lens combinations. In 1856 L. von Seidel showed clearly the defects we have to overcome in lenses, and now we can correct them; a complete account of his investigation was not available before 1880, however, and it was only in 1898 that the Bavarian Academy published a full edition of his memoirs, upon which S. P. Thompson dwelt in his fourth Taylor memorial lecture. Dr. Glazebrook referred repeatedly to this lecture by Professor Thompson. By 1870 the necessity of a new departure was recognised in England, and Stokes and Harcourt began to experiment on new glasses to meet the demands of optical theory: work that was soon afterwards taken up by Abbe and Schott, in Jena, with such signal success.

Dr. Glazebrook explained how problems, such as the imperfections of lenses offer are attacked. We must first get our data settled and stated; to express them in mathematical symbols we have to make assumptions simplifying the problem, though such assumptions may appear strained; when the formula is solved, we have to investigate its physical meaning, and to apply it. The phenomena are so complicated, even with perfect lenses, that we confine ourselves, with Gauss, to flat object problems, and, in the first instance, to monochromatic light. With these restrictions we have to consider five chief sources of error. Firstly, rays parallel to the optical axis are not all brought to the same focus; this defect is known as spherical aberration. Secondly, a point in the object, situated at a small distance off the optical axis, will give one image, produced by the rays falling upon the central portion of the lens, and another image produced by the marginal rays; this very

common defect of lenses is known as zonal aberration, coma, or obliquity effect. Thirdly, when the rays are more oblique, they are united, not at a point, but in a line, the primary focal line; they spread out again afterwards, and are once more brought to a secondary focal line. A flat object gives two more or less curved images, which coincide only at the principal focus; and when we observe the image of a point on a screen we see, at various distances, a vertical line, an ellipse (vertical axis long), another ellipse (vertical axis short), and a horizontal line. The field of a point is hence not stigmatic (not a point). The fourth and fifth defects—curvature of field and distortion—are connected with these aberrations. Seidel gave definite equations for the differences between the actual and the correct image; when his s_1 is zero, the lens is corrected for spherical aberration; when $s_2 = 0$, for zonal aberration; when $s_3 = 0$, for astigmatism, and so on. To satisfy all his equations, when $s_1 + s_2 + s_3 + s_4 + s_5 = 0$, is impossible with one lens; for we can, if restricted to one material, only vary thickness and curvature. But when we combine lenses, and change the materials to obtain the desired refraction and dispersion, we can also correct for s_6 (chromatic aberration), which was incompatible with flatness of field, until new optical glasses were prepared out of hitherto unused materials in suitable proportions. The remarkable results achieved were explained by diagrams which illustrated Steinheil's skill. When Steinheil commenced his researches, the image of a star in an ordinary lens appeared at the focus as a small circle with a dot in its centre; one degree from the centre of the lens it produced three more or less concentric oval curves. If the screen were pushed in or out by a fraction of a millimetre, the circle changed into three large concentric circles, and the ovals into three oddly shaped curves. Applying the corrections, Steinheil succeeded in suppressing these peculiar defects more and more.

Dr. Glazebrook then passed to instruments, spherometers, etc., designed for the systematic examination of lenses and exact measurements of their defects. An ingenious instrument of this kind—an optical bench designed and constructed by Messrs. Beck, and presented by Mr. Beck and Mr. Stuart to the National Physical Laboratory—was on view. It consists, Dr. Glazebrook pointed out, of many parts sliding in one another, and swinging in ball bearings about their centres, together or separately, and it can be used in a variety of ways. A graduated screen or an artificial star serves as an object. The lens revolves in its carrier on two hundred balls; both the lens and the cross hair-screen can be swung, and the microscope be racked; the equivalent focal distance is measured in the usual way, or half this distance is determined by shifting the lens through a certain arc; measurements for astigmatism can be made within a few minutes. Dr. Glazebrook also referred to the novel systems of testing due to Professor Hartmann. Instead of examining a distant object, Hartmann prefers, for certain purposes, to bring the object close to the lens; and he has further devised a method of tracing the paths of distinct rays. As worked out by Mr. Chalmers, this method consists in covering the lens under test with a diaphragm perforated at three, five, or more spots. The rays passing through these apertures will not converge to a common focus, but they will cross more or less near the focus; and if we place a sensitised plate between the lens and the focus, and another plate afterwards beyond the focus, the two pictures obtained will enable us to determine the directions in which the rays travelled. The obliquity of the incident rays is varied in such experiments.

Having shown examples of the excellent fruit which the application of these various methods of measurements has borne, Dr. Glazebrook concluded by expressing his regret that the National Physical Laboratory had so far not been able to apply any significant portion of its scanty grant to the aid of the optician. He would be a real benefactor who brought home to the Government the full recognition of the fact that such institutions had been created in order to facilitate the application of science to manufactures. He was glad, however, to announce that an optical convention would be held in London next May, which, it was hoped, would bring together practical and scientific opticians from all parts of the country for common deliberation concerning all sides of the question: theoretical, practical, and commercial.

We call the above report of the Traill Taylor Memorial Lecture from our contemporary, "Engineering," as this year we have not received from the hon. secretary of the Traill Taylor Memorial Fund, probably for very good reasons from his point of view, the lecture for report in full in our pages as in previous years.

* Muller in *Drude Ann.*, XII, p. 767, states there is an increased absorption of the copper nitrates and acetates upon dilution.

PHOTOGRAPHY COMPARED WITH PAINTING.

Although painters admit that photography can render the minute intricate details of Nature more faithfully than brush or pencil can do, they are apt to think it a mere mechanical operation in which little skill is required to meet with success, and they contend it is the light that records the impression on the plate, and therefore is unworthy of a place in the category of art. They imagine it requires no culture to arrange a composition, or to select the best point of view that will suit a subject, and to know when to seize it when the lighting is most effective, to avoid violent contrasts, overcome spottiness, to secure the greatest amount of relief, at the same time preserving important detail often lost in heavy shade.

Whatever opinions we hold respecting their views on this subject, the fact remains photography depicts Nature truthfully, in her simple, unadorned dress, and does not attempt to wrap its themes in mysterious symbols and enigmatical allegory—a caprice we often see of the painter. These knights of the brush portray historical events oftentimes from inaccurate description and conjecture, that accounts for the many different interpretations we see of the same subject bearing little similarity to each other. Photography on the other hand depicts scenes and episodes as they actually are, absolute facts we cannot refute, and the pictures obtained can be reproduced to any extent, and by many processes; this being one advantage over painting.

Photography has contributed much knowledge to mankind in general, and added many fresh pages to the book of Natural History; we have only to glance through the magazines to-day to prove this fact. Every phase of bird-life it has depicted from the embryo chick to the full-grown mature bird; even in those remote isolated tropical islands the camera has been much in evidence of late in taking those bird farms where the sacred albatross swarm in such immense numbers, and that make quite an industry in collecting their eggs. The queer methods and the subtle means employed to conceal the operator and his camera from view, when snap-shooting those gay-plumed birds known as flamingoes, are there shown in those unique pictures. Were it not for the camera we should know but little respecting the haunts and habits of these rare specimens of the feathered species.

By the camera's aid successful pictures have been taken in the jungle and swamp, showing voracious beasts in their wild state roaming in search of their prey, and good photos of savage reptiles basking 'neath the tropic sun have been secured. Gambier Bolton, Sir H. Johnston, and J. Lodge have made a speciality of this kind of work, and the success they have achieved is known to all and needs no further comment here. In this risky work the painter would utterly fail.

If the camera lacks that imitative vision which painters possess, it has points in its favour that compensate for that deficiency. Just think of the service it has rendered to the cause of science when accompanying those expeditions sent out to explore the unbeaten tracks unknown to the mind of man, and the pictures attained speak for themselves when thrown on the lantern screen, which later on we find reproduced in magazines to illustrate articles on the subject.

If we take a retrospect and compare the respective progress of painting and photography in the past, we shall find the latter has flourished, and the former—paradoxically speaking—has gone backward. The works of the old masters, such as Titian, Michael Angelo, Raphael, of the Florentine school, Velasquez, and a few others, surpass the productions of our contemporary modern painters, the Royal Academicians; for to-day the gems of those old masters are in great demand and fetch fancy prices, but the works of living R.A.'s are ignored and not appreciated, and when sold go for a mere trifle in comparison.

But if we now compare the progress of photography we shall find a striking contrast. Let us go back to its inception, when Niépce and Daguerre joined in partnership and submitted to the world the results of their labours, and see from what a minute germ this vast power has sprung. It was thought then very astonishing that a portrait could be taken in a few minutes instead of having to give many sittings of long duration to a painter; and if we compare the ill-defined smudge of seventy years ago that required minutes—in some cases hours—to produce, with the highly elaborate, delicate, and exquisitely-finished results we now get, and that with an ex-

posure made with a flying shutter—because the hand is not quick enough—who can say we have not advanced with wonderful strides? Photography has proved one of the greatest aids to science to-day, and the achievements it has wrought are simply marvellous; its influence and power are universally acknowledged, bringing all countries in touch with each other, and thus proving the adage of the immortal bard, "One touch of Nature makes the whole world kin."

TRIPOD.

ORTOL. ITS ADAPTABILITY TO PROFESSIONAL USES AND GENERAL APPLICATION.

AMONG the new developers that have stood the test of time and have substantiated the claims made for them by many prominent workers, Ortol has proven a particular favourite. By the great class of professional and amateur photographers who, accustomed to the handling of Pyro were eagerly awaiting the arrival of a substitute that would possess most of its unarguable characteristics without its inconvenience and that could be used by them without the wearisome necessity of studying for weeks a new system of development, Ortol has been hailed with delight. As long ago as 1899 so conservative a man as W. D. Welford expressed himself as follows: "As a user and believer for many years in that reagent (Pyro) far be it from me to cast even a shadow of suspicion upon its virtues, and I confess, that up to the present, not one of the developers introduced since Pyro has been equal to it as an all around first-class developing agent. Minor advantages have been gained, there can be no cavilling at this statement—skirmishes have been successful, but when the main battle has come off, Pyro has always won.

"I make the assertion that, if any developer will shake Pyro to its foundations, it is Ortol. It is no use saying that it will take the place of the other, because there are many who will never change—but I'll guarantee that, if Ortol be given a three months' earnest trial, spread over all classes of work, the dear old Pyro bottle will quickly find its way to Stevens."

This extract has been given in extenso because it expresses very well the general consensus of opinion obtaining among our best scientific and professional workers, including some of the staunchest supporters of Pyrogallic development, such as Professor H. C. Bothamley, Professor H. W. Vogel, Schnauss, Pizighelli, J. Gaedicke, Andrew Pringle, Professor Stolze and others.

Ortol is a chemical combination of 1 molecule, 1.4 dioxybenzol, with 2 molecules Ortho-methyl-amido-phenal-sulphate. The latter salt by itself a very fine developer, giving negatives of exquisite delicate gradation but lacking generally in density. The possibility of combining it chemically with a substance of great covering power like 1.4 dioxybenzol (hydrochinon), or 1.2 diaxybenzol (Pyroca-techin) enabled Dr. Anderson and J. Hauff to produce a developer admirably balanced in its chemical composition and adapted to the widest range of work. Like with Pyro, the image of an Ortol developed negative appears step by step and gains steadily in density; the progress of development can be easily regulated, hastened or slackened, following exactly the same principles and the same methods as with Pyro development; the only difference is that Ortol has taken the place of Pyro in the formula. Unlike Pyro, however, it can be usefully made up as a single solution, can be used several times over, is excellent for gaslight and for bromide papers alike, for transparencies and for lantern slides as well. It does not stain plate, paper, or fingers, even when old, and has excellent keeping quality. The colour of the negative can be regulated at will between black and brown; the rendering of tone values is perfect. The speed of development is slightly greater than that obtainable with Pyro, slower than that of Metol. It is readily amenable to the action of bromide of potassium, or other restrainer, including the physical restrainers, such as cold temperature of bath, colloids, sugar, etc., etc., and in consequence it is extremely elastic and able to compensate great excesses of exposure. It is also excellent for tank development on account of its keeping and non-staining qualities. Finally, it should be mentioned that below 70 deg. F., frilling is practically unknown with this developer, as it exercises a decided tanning action on the gelatine.

Dr. Eder, who made extensive experiments on the comparative behaviour of the different developing substances, speaks very highly of

the advisable adaptability of Ortol to general work. Sensitometric tests prove that Ortol will show when properly handled a higher sensitometer number than Pyro (Scheiner Sensitometer), and even with a shorter development yield more density as well. For instance, two similar exposures having been given with foregoing instrument and developed one with Pyro, the other with Ortol, all conditions of temperature being equal, Ortol allowed a reading of 15 Scheiner after two and a half minutes' development (photo grammetric density 0.41), as against 14 deg. Sch. (density 0.29) for Pyro, and of 17 deg. Sch. (density 0.49), after five minutes' development, as against 15 deg. Sch. (density 0.35) for Pyro. With Ortol a few drops of bromide of potash of citrate of potash solution 1.10 go a long way and act very powerfully as restrainers.

For great underexposures the best methods are either to resort to stand development or to add to the normal developer a few drops of a 10 per cent. solution of caustic soda or caustic potash.

As a general developer for all around work the following formula will be found exceedingly useful:

A.—Water	20 oz.
Metabisulphite potash	70 gr.
Ortol	140 gr.
B.—Water	20 oz.
Soda carbonate crystals	2 oz.
Soda sulphite crystals	1½ oz.

Normal developer 1 part A, 1 part B, and 1 part of water.

Greater softness is obtained by increasing the water or alkali or both.

Greater contrast by increasing the quantity of "A" and adding bromide of potassium (1.10 solution), as required.

For very crucial work, however, and when the greatest power of modification is required, it is best to make up the developer in three solutions after the suggestion of W. D. Walford, the sulphite being kept separate from the carbonate, thus:

A.—Ortol	1 oz.
Metabisulphite potash	½ oz.
Water	60 oz.
B.—Carbonate of soda crys.	8 oz.
Water	50 oz.

Some writers suggest as an addition to this solution 1-3 ounce of a 5 per cent. solution of hypo.

C.—Sulphite of soda crystals	10 oz.
Water	40 oz.

Normal exposure, vigorous negative: 1 part A, ½ part B, ¼ part C. Bromide solution 1.10 as necessary, generally about two grains per ounce of mixed developers.

Normal exposure, softer negative, add 2 to 3 parts of water to above and reduce the amount of bromide to ½ to 1 gr. per ounce.

Over exposure, 1 part A, ¼ part B, ½ part C.

Bromide 5 to 10 grains per ounce.

Under exposure, 1 part A, 1 part B, 3 to 4 parts of water, no bromide.

After the negative is fully developed, but for the finest detail, and it is feared that density might be too great, a good method is to flood the plate quickly with a weak solution of soda, say 1 part B and 6 to 8 parts of water. After having allowed it to act for a few seconds rinse the plate and immerse without delay in the fixing bath.

As previously stated, Ortol is admirably adapted to the development of bromide paper yielding with them, under proper conditions, a beautiful black deposit, which comes nearer to that obtained with Ferrous-oxalate than is possible with any other developer. We give here Hauff's original formula:

Water	1,000 gms. 32 oz.
Metabisulphite potash	7.5 gms. ¼ oz.
Ortol	15 gms. ½ oz.
Water	1,000 gms. 32 oz.
Carb. of potash	60 gms. 2 oz.
Soda sulphite crystals	100 gms. 6 oz.
Potassium bromide	1-2 gms. 15-30 grs.

Normal developer: One part A, 1 part B, 4 parts water. With

warm water the resulting image will be softer with less, distinctly harder.

For gaslight papers the same developer may be used to great advantage as follows:

One part A, 1 part B, from no water to two parts of water. By modifying the amount of the latter and the amount of the bromide, the colour of the print can be modified to suit the taste of the operator from pure black to brown, and even to red, by further addition of some carbonate of ammonia, an ammonia bromide, and the suppression of the soda sulphite in solution B.

Any of the formulas previously given is admirably adapted for the production of transparencies and lantern slides, and it is unnecessary to enter into further particulars on that subject. We cannot resist, however, the temptation to reproduce the following formula (Andrew Pringle), which has given in many hands the first warm-black and brown slides we have ever seen.

A.—Water	20 oz.
Metabisulphite potash	34 gr.
Ortol	150 gr.
B.—Water	20 oz.
Carbonate soda crystals	3½ oz.
Soda sulphite crystals	2½ oz.

One part A, 1 part B, 1 part of water, and from ½ to 2 grains potassium bromide to the ounce of mixed developer. We strongly advise lantern-slide makers to try the foregoing, preferably on some slow plates, and they will find it all that can be desired. We may add that the same formula is very well suited for the development of plates and bromide paper.

We have referred to the use of Ortol for stand development. By it negatives of admirable delicacy and gradation may be obtained even from very much underexposed plates. Usually the speed must be so regulated that development will be completed within an hour. Occasionally this might be extended to three hours. There is no advantage, however, in fact rather prejudicial. The normal developer may simply be diluted from 30 to 50 times, or, if very slow development be preferred, the following might be substituted for it:

Ortol	20 gr.
Soda sulphite crystals	150 gr.
Metabisulphite of potash	10 gr.
Soda carbonate	130 gr.
Potassium bromide	3 gr.

Water, about one pint.

More or less water will respectively slacken or increase the speed of development.

All the formulas given above have been carefully chosen from the most popular ones that have stood the test of thorough investigation and practical work. We wish, however, to caution the reader not to use them without taking into account the fact that every formula published has to be adjusted to the particular plate one is using as well as to the ultimate results contemplated in the print. This is true of Ortol, of Pyro, or of any other developer, but for a photographer accustomed to Pyrogallic acid development Ortol will have but pleasant surprises, and he need not modify his ordinary methods and processes to suit the new reagent. The change from the one to the other will cause him no trouble or spoiled plates if he has read carefully the preceding remarks, and he will feel pleasantly gratified at the advantage of using Ortol.—"The Photo-American."

On Friday evening last week the Fire Brigade was called to a fire which had been discovered in the premises of Mr. C. R. Chaplin, photographer, Rose Cottage, Sea View Terrace, Colwyn Bay. It was found that the wooden partition of the picture-framing room was all in flames, and were it not for the prompt action of the Brigade and some neighbours, the whole building would have been destroyed. As it was, damage to the extent of about £60 was done, this loss being only partly covered by insurance. It is not known how the fire originated, but it is surmised that a drying-cloth hanging over the door was blown by a draught over the gas-flame and was thus ignited, the fire passing to the woodwork.

FIRST AMERICAN SALON.

The following abstract of a note by Mr. F. Dundas Todd on the above subject will be read with interest, and it is a strong argument for the trial in England of the system of having a jury composed of artists and artists only, in order that we may have some of our own strange gods overthrown and bring some of us back to the paths of sanity and common sense:—

Notwithstanding the pooh-poohing that has been liberally poured upon the proposition by individuals on both sides of the Atlantic, the photographic world has practically received it with open arms, and pictures by the thousand have been pouring into New York during the month of November. At the date I am writing I am unable to give the exact figures, but a rough estimate is to the effect that about seventy-five hundred frames were contributed from America and about sixteen hundred were received from abroad. To handle such an enormous collection was in itself no mean task, and on a recent visit to the rooms of the Metropolitan Camera Club I found over one dozen members as busy as bees, trying to reduce order out of chaos.

Even more remarkable than the numbers submitted is the status of the jury of selection, which consists of the most eminent artists this country has ever seen. On the first day of selection no less than eleven of them appeared and on the second day an even dozen, comprising such men of fame as John La Farge, Childe Hassam, Edwin H. Blashfield, and Kenyon Cox, being a jury the like of which never was brought together in the history of photography, and one whose opinion must unquestionably be final in photographic art matters, because whoever cavils at the decision of such a jury can appeal to no higher court.

I happened to be in New York city on the first day of the judging, and on the day following, along with a number of brother editors, I was permitted to look through such pictures as had been selected in order that I might make a choice of a few pictures for reproduction in this month's issue, so that the readers might have an opportunity of forming a broad estimate of the character of the selection made by the jury. The impression that I received was rather startling, because, much to my surprise, I found that this jury of artists had—use a slang expression—practically upset the photographic apple cart, for they had, in a large number of instances, overthrown the strange gods the photographic world had in former years bowed down to and worshipped. Some of the first pictures to catch my eye were models of perfect definition and pure photography, in fact, would gladly be selected by lens, plate, and paper manufacturers as first-class mediums for advertising the quality of their goods; such pictures as we have never seen in salons for many years. On the other hand, one could find many specimens of the mud-flat school and my offhand opinion was that the most striking feature of the display to the average man will be its broad catholicity, for here he will find everything to his taste and much that will not please him. On the walls will be pictures that are fuzzy, some that are sharp, many that are murky, and others that are as clear as fine definition can make them. In subjects there will be as much variety. A casual glance shows snow scenes, waterscapes, landscapes, portraits, genre subjects, and, in fact, everything that one expects to be rendered as pictorial photography.

I did not have an opportunity of looking over the rejected mass of pictures, but I was informed that many that had figured in past salons had been unfortunate in this; while many that had been rejected formerly were now to hang on the walls—the labels on the back of the pictures being accepted as a proof of this.

The foreign pictures submitted had not found their way out of the custom-house when I was in New York city, but a recent letter from Mr. Bell informs me that both England and many other European countries are splendidly represented, notwithstanding the incessant efforts to belittle the salon.

The most important conclusion that came to my mind from the brief overhauling of such pictures as had been selected on the first day is this: That the jury of the highest ability in the artistic world has proclaimed to everyone that it is possible to produce pictorial photographs by straight photographic methods, and it seems to me that the world-wide proclamation of this fact will give incentive to those who at present have really no sympathy with the faking methods so much in vogue.

New Books.

"Subject List of Books on Fine and Graphic Arts (including Photography) and Art Industries in the Library of the Patent Office." Published at the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C. Price 6d.

The Librarians of the Patent Office have withdrawn the list dealing only with photographic books and periodicals and have substituted for it the above. In doing so they have somewhat modified their classification, and have included the volumes added to the library since the issue of the previous list. As the Patent Office possesses the finest public collection of technical literature in this country, if not in the world, we shall refer further to this catalogue in our next issue. In this issue, however, we print the list of periodicals in the belief that it will be of value to those who have any occasion to undertake any research into the literature of photography.

"Penrose's Pictorial Annual for 1904." Edited by William Gamble. Published by Penrose and Co., 109, Farringdon Road, London, E.C.

Known probably as well by its sub-title, "The Process Year-Book," this annual has made a distinct place for itself in photographic literature, which also seems quite unattainable by any other work, and personally we know of no other which can take its place. This, the tenth volume, is no whit less interesting, instructive, or poorer in illustration than its predecessors; in fact, one must admit that there is generally an advance. To every process worker, or to every photographer who is interested in keeping a record of one of the largest and most important applications of photography this book is indispensable, for to him who has little or no interest in the text the illustrations will provide not only pleasure, but profit in the examination of their beauties, which are of a very high standard both in monochrome and colour. Handsomely bound and beautifully printed, the volume is alike a credit to the editor, the publishers, and the printers.

Patent News.

The following applications for patents were made between December 12 and December 17, 1904:—

Coloured Photography.—No. 27,141. "Coloured Photography." Herman Dahl.

Lighting Powders.—No. 27,267. "Improvements in and relating to powders or compositions for use in artificial lighting for photographic purposes." Gottlieb Krebs.

Lighting Powders.—No. 27,268. "Improvements in and relating to powders or compositions for use in artificial lighting especially for photographic purposes." Gottlieb Krebs.

Shutters.—No. 27,375. "Improvements in and relating to camera shutters." William Frederic Butcher.

Photographic Identification.—No. 27,384. "A new or improved method for the utilisation of photography for the identification of living objects, articles of furniture, works of art, and the like." Herbert John Haddan.

Colour Photography.—No. 27,418. "Improvements in colour photography, animated or otherwise." William Norman Lascelles Davidson.

Flash Powder.—No. 27,465. "Improvements in flash powder for producing artificial light for photographic and other purposes." Hans Lutke, Paul Arndt, and Ernst Leopold Lowengard.

Flash-light Cartridges.—No. 27,466. "Improvements in flashlight cartridges for producing artificial light for photographic and other purposes." Hans Lutke, Paul Arndt, and Ernst Leopold Lowengard.

Artificial Light.—No. 27,589. "Improved artificial light for photographic purposes." George Wilson Morgan.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
2.....	South London Photo. Society....	<i>Some Architectural Details.</i> Mr. H. Creighton Beckett.
2.....	Bowes Pk. and Dis. Ph. Sec.	<i>Enlarging by Artificial Light.</i> Mr. H. Stuart.
2.....	Southampton Camera Club	The Annual General Meeting.
2.....	Nelson Photographic Society	Open Night.
3.....	Border City Camera Club	Members' Lantern Slides.
3.....	Sheffield Photographic Society	<i>Amateur Photographer Prize Competition Slides.</i>
4.....	Edinburgh Photo. Society	<i>Michael Angelo.</i> Illustrated. Mrs. J. Lauder Thomson.
4.....	G.E.R. Mechanics' Institution	<i>Enlarging at Home, without Expensive Apparatus.</i> Demonstrated. Mr. Green.
4.....	Boro' Poly. Photo. Society	Members' Night.—An Exhibition Talk.
5.....	Hull Photographic Society	<i>The Platinotype Process.</i> Demonstrated. Rev. C. O. Stewart.
5.....	Watford Camera Club	Holiday Prints. Competition.
5.....	Gateshead Camera Club	<i>Pictorial Composition.</i> Mr. W. F. White.
5.....	Southport Photo. Society	<i>Toning of Bromide Prints and Lantern Slides and the Intensification and Reduction of Negatives.</i> Demonstrated. Messrs. Burroughs, Wellcome, & Co.
5.....	Batley and District Photo. Soc.	<i>A Naturalist's Rambles with his Camera.</i> Mr. Riley Fortune, F.Z.S.

ROYAL PHOTOGRAPHIC SOCIETY.

TECHNICAL Meeting, December 20; General Waterhouse in the chair. A paper by Mr. Max Levy on "Half tone Screens" was read.—The lecturer dealt shortly with the early historical side from Nièpce and Talbot, mentioning the discovery by Ponton, in 1839, of the properties of chrome gelatine compounds, giving rise to the colotype process; then Woodbury type and photo-lithography.

The half-tone process, at the present time the simplest of the photo-mechanical processes, was only developed gradually. Mr. Levy's own experience of a connection with photo-mechanical work dates back to 1875, when he joined his elder brother, Louis Edward Levy, in Baltimore, who had just patented the original Levy type process.

At this time there were only three parties commercially engaged in photo-engraving in America.

From 1881-1885 the method of etching on zinc from an impression obtained directly on bichromatised albumen came into general use. This advance removed a whole range of difficulties in the way of the progress of the half-tone process. The last great difficulty now presented itself in the way of obtaining a suitable ruled screen for the work. Meisenbach, in Berlin, was the first to appeal to the trade, offering large printed sheets, and also rulings on glass, from which photographic copies were made by the user. Mr. Ives had abandoned his original process, and was using screens which he ruled for himself.

From about 1886 Mr. Levy gave himself to the work of making a proper ruling for a screen, making rulings on steel and copper plates and also on glass, the latter being one of the most elusive undertakings he has ever attempted. He determined that two things were vitally important—the one an automatic machine, which could be taken, if necessary, to some quiet spot in the country; and the second, a suitably ground and polished cutting tool of diamond, as all other substances had proved totally inadequate.

To design an automatic machine on the lines of the one which he had was Mr. Levy's first task, and, after gradually overcoming the difficulties met with, about the fall of 1888 he had an automatic machine ready for the belt. With this and a suitable diamond point it was possible, with sufficient effort, to produce a thoroughly good and serviceable ruling up to 15 x 12 inches, and of the necessary fineness for direct work. His brother was impressed with the idea that if the lines could be etched into the glass and filled with a black pigment it would produce an ideally perfect screen. After numerous attempts complete success ensued, but by no means ended the difficulties encountered in producing screens commercially. In the fall of 1890 Mr. Max Levy started to work, and about six months later a commercially satisfactory screen was produced. At this time Messrs. Levy and Mr. Ives were the only users of cross-line screens. As is well known, the introduction of these screens gave a great impetus to half-tone work. The study of the underlying optical phenomena was taken up with a view to establishing the best possible

relation between the black and white elements of the screen. Some of the results of these studies are contained in a paper read before the Photographic Society of Philadelphia in 1896. These studies tended to establish the equal black and white line as the best proportion.

About 1890 a screen of 120 lines to the inch was nearly as fine a ruling as could be advantageously used for high-class work, and 130 lines to the inch for small and fine work. Nowadays 200-line ruling is not at all uncommon, and screens of 300 and 400 lines to the inch find occasional use.

The years 1896 and subsequent gave rise to a demand for something which should be less flat and have a less mechanical texture than was characteristic of the half-tone produced by the cross-line screen. The outcome of this was the four-line screen, which showed a distinct advance in the rendering of detail and variety of tones, but the mechanical character of the screen was somewhat exaggerated.

After dealing shortly with the irregular grained printing plate, the lecturer closed his remarks.

SOUTHAMPTON CAMERA CLUB.

THE usual weekly meeting of the above was held on the 19th inst., while the club exhibition was in progress, opportunity being made to present the awards to the successful exhibitors. After the competition slides had been put through the lantern, the Mayor, Colonel Bance, J.P., in congratulating the club upon the excellent display in all the classes at the exhibition, made some very interesting references to his early experience in the art, and then proceeded to distribute the plaques and medals. Later the Mayor was called upon to make another very interesting presentation, in the shape of an album containing a specimen of work of practically every member of the club to the esteemed president, Mr. W. B. Hill. Mr. Kimber, the hon. secretary, expressed the feelings of the members towards the president in the warmest terms, and that gentleman having replied the meeting terminated with a vote of thanks to the Mayor for his attendance.

BURTON AND Y.M.C.A. PHOTOGRAPHIC SOCIETY.

THE above society held a general meeting on Monday, December 19, when there was a good attendance. The result of the judging of pictures sent in for the competition for "the best photograph taken during the current year" was announced, Mr. T. Grundy being awarded the silver medal, the bronze medal going to Mr. J. W. Woodhead; judge, the Rev. E. Gilmour. These are the first medals presented by the society. There was a large entry of high-class work. The annual election of officers took place, when it was proposed that Mr. Peet be asked to accept the presidency and the Rev. E. Gilmour the vice-presidency. The following officers were elected: Chairman, Mr. Knight; secretary, Mr. G. Moore; reporting secretary, Mr. T. Grundy; committee, Messrs. Abrahams, Lawley, Shreeves, Jefferson, Woodhead, and Barrett. A very satisfactory balance sheet, showing improvement on previous years, was presented by the secretary, who also announced an excellent programme for the ensuing session.

FORTHCOMING EXHIBITIONS.

January 12-14, 1905.—Boston Camera Club. Hon. Secretary, H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Mitchell, 180, Browning Road, Manor Road, E.

January 23-28, 1905.—Lancaster Photographic Society. Hon. Sec., R. T. Simpson, 21, Cheapside, Lancaster.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grande-Armée, à Marseille.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 16-18, 1905.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 25-March 4, 1905.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11, 1905.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14, 1905.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

April, 1905.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15, 1905.—Photographic Society of Ireland. Hon. Sec., R. Benson, 35, Molesworth Street, Dublin.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E..

Commercial & Legal Intelligence

At an extraordinary general meeting of the Alliance Roll Film Camera Company, duly convened, and held at 88, High Holborn, London, W.C., on the 29th day of November, 1904, the following special resolution was duly passed; and at a subsequent extraordinary general meeting, also duly convened and held at the same place on the 14th day of December, 1904, the following special resolution was duly confirmed: "That the company be wound up voluntarily, and that Mr. J. D. Garside, of 34, New Bridge Street, E.C., be and he is hereby appointed liquidator for the purposes of such winding up."

A CASE of Likeness.—Wishing to make presents to his mother and his fiancée, Horace Cope, a Stalybridge tailor, obtained coloured photographs of himself from Mr. Hallas, of Market Street. He did not like the pictures, and refused payment. So he had to answer a claim for two guineas in the Salford Hundred Court of Record last week. Obviously the easiest way of settling the case was for the jury to compare the presentments with the original, and this was done. "Had that man's face been dabbed in a pat of butter you could not have got a better likeness," commented Mr. Ray, who appeared for the photographer. All Judge Shee had to ask the jury was, "Do you think these are reasonably good coloured photographs?" and the jury thought they were.

A CHARGE Withdrawn.—Mr. A. Muir-Wilson appeared on Thursday at Barnsley Borough Police Court in a case mentioned a week ago in which Edward Dawes, photographer, of Pontefract Street, Barnsley, was charged with having embezzled £8, the property of Denis R. Thompson, photographer, High Street, Sheffield. A week ago Thompson wrote, asking that the case might be withdrawn, but the Bench refused to permit this to be done so summarily. Mr. Wilson, for Thompson, said he was there to do what his client ought to have done, instead of writing to the Court. He knew, almost better than anyone else, that Courts of that kind must not be used for anything suggestive of a debt-collecting agency, but his client acted with fairness, if he did not treat the Court with proper courtesy. Mr. Wilson related the facts of the case, stating that at the outset his client believed Dawes' explanation to be a fairy tale. He added that for the mistake his client had had to pay. "He has had to pay me," added Mr. Wilson, "for, as your Worship may know, I do not come here for any nominal fee." Mr. Rideal observed that his client had a good answer to the charges, and he asked that the case might be dismissed, in justice to his client's character. The Mayor replied that he thought the withdrawal of the case, and the observations of Mr. Wilson, met the matter, and the case was accordingly struck out.

News and Notes.

THE Aberdeen Photo Art Club held its fortnightly meeting at 62, Fonthill Road, last week. The President, Mr. G. L. Smith, occupied the chair. Mr. D. Duff read the criticisms on "Christmas cards" sent in for competition. The first places in this competition were taken by Mr. John D. Stephen, Miss M. R. Smith, and Mr. J. Dalgity. The helpful and instructive criticisms by the adjudicators, Mr. Findlay and Mr. David, were heartily appreciated. The President gave a practical demonstration on "Mounting," aided by prints sent in by the competition judges. Mr. Smith showed, by careful selection of the tints used in building up a mount, how much pictorial value can be added to a print by such means. The remainder of the evening was occupied by a demonstration on "Flashlight Photography," by Mr. J. D. Stephen. The demonstrator, in an interesting manner, showed the various easy methods by which photography may be employed during the dark days and nights of winter. Mr. Stephen purposely employed the simplest means, which, he said, could be accessible to every worker. His lesson in this attractive branch of photography was much appreciated by the members.

THE third in-door meeting of the Derby Photographic Society was held last week. In the course of the evening the President, Dr. E. Collier Green, commented upon the fact that this was the inaugural meeting in the new home of the society, which promised to be very comfortable, and eminently suitable for the purpose. The hon. secretary, Mr. A. H. Bennett, announced the awards made by Sir William Abney, to whom the competition prints had been submitted for adjudication. In the open class Sir William awarded the medal to Mr. J. Huxley, of Derby, for a picture which the judge, in his notes on the competition, said was delicate, had a good deal of feeling about it, and was technically good. In the novices' class the medal went to Mr. J. W. Tempest, of Duffield, whose work was described as excellent, the "Yorkshire Beck" being technically and artistically good, and a beautiful photograph. The whole of the competition prints were hung on the walls of the room for the inspection of members. Two new members were elected, and Mr. W. R. Bland then proceeded to read an instructive lecture on "Principles of Composition and Selection of Subject," by Mr. W. E. Tindall, R.B.A. The lecture was illustrated by lantern slides, the lantern being manipulated by the hon. lanternists, Messrs. S. Finney, C. E. Etches, and W. Wilkinson.

WARPED Printing Frames.—A local amateur (says the "Oxford Times") for some time past had been considerably exercised by a fuzziness which appeared in the centre of some prints of an architectural subject. Persons who examined the print were unanimous as to "flare-spot," and the unfortunate worker, whose camera was but a recent investment, was considerably dismayed. Curiously enough, prints from quarter-plates which had been used in the same camera with an adapter developed no such defects, and the mystery thickened. Determined to discover the source of the trouble, the victim carefully examined the half-plate negatives which had given the faulty prints, and finding every portion of the image sharp, he turned his attention to the printing frame, and, after careful examination of the hinged back, found that the wood had warped considerably in the centre, rendering it impossible to get sufficient pressure on the paper to secure a sharp image. It is evident that other persons have had similar experiences, for the manufacturers are carefully rabbetting the backs of all the decent frames made at the present moment, and this without any addition to charge of the old and inferior article. Printing frames are but one of the many minor necessities in photographer's equipment which need periodic overhaul and which may cause untold disappointment and expense if neglected.

MORE Rays.—It might be thought that discovery in the direction of obscure rays would be resting awhile; but still another set of rays is claimed to have been discovered by M. di Brazza, a student of Liège. Their results have been rendered visible to the outsider by employment of orthochromatic plates. Professor Charpentier, of Nancy, had surmised that the brain is the seat of the emission of the N-rays, and M. di Brazza thinks he has proved it and that his rays, called I-rays, differ from N-rays by being able to pass through moist substances. When an experimenter concentrates his will, the

I-rays from his brain cause changes of luminosity in a phosphorescent tablet. When his attention is not concentrated, the light does not flicker. The rays are not emitted equally from every part of the head. They are nil at the forehead and upper part of Broca's centre, increase at the temples and eyes, and reach the maximum behind the ears. A question of profound importance is hereby raised. If it be possible to produce a visible physical effect on objects external to an experimenter or operator, what ground is left to stand on by those who object to the idea that the person's mind is capable of influencing that of another without the ordinary senses of touch, hearing, seeing, etc., being brought into play? If M. di Brazza can bring his orthochromatic plate results into the court of science, and win a verdict in favour of I-rays, a most momentous epoch will have been initiated.

THE First Christmas Cards.—In these days of photographic greeting cards, the following from the pen of Mr. Percy Collins will be read with interest. We clip it from "The World's Work" for January, 1905:—When we realise that for several seasons past something like 35,000,000 Christmas cards have been transmitted annually through the British Post Office alone, the fact that the production of Christmas cards forms no inconsiderable item in the world's work is self evident. Of all the national institutions with which we are accustomed to celebrate the festive season, the card of kindly greeting can boast of having had the smallest beginning and the most steady growth. Not a few among us can look back at the time when Christmas brought no cards; for, as far as can be ascertained, the first genuine Christmas card was not entrusted to the care of the Post Office until the year 1844 or thereabouts. The sender of this solitary token of goodwill was the late W. A. Dobson, R.A.—at that time just a very young man earning his living as a master of the Government School of Design at Birmingham. He had a friend from whom he had received certain courtesies of which he desired to show his especial appreciation. The time was Christmas. So after some thought he made a sketch symbolising the spirit of the festive season and posted it to his friend. This sketch—the first Christmas card of which any record is preserved—was done on a piece of Bristol board about twice the size of the modern letter-card. It depicted a family group toasting absent friends among appropriate surroundings of holly and evergreens, and was supported by panels illustrating deeds of benevolence. The unpretentious little picture gave so much pleasure to its recipient and was the cause of so much envious interest among his friends, that Mr. Dobson was prevailed upon to repeat his experiment. Then, two years later, he etched another design, had a block made by a local lithographer, and posted copies to all his friends. A really happy inspiration does not long remain the exclusive property of the inspired. The next year, several of Mr. Dobson's artistic acquaintances were producing their own Christmas cards and sending them to their own friends; and with each succeeding season this circle of imitators grew wider. Ten years or so later, some one suddenly saw money in the notion, and thus the Christmas card of commerce was put upon the market.

COPYRIGHT in Magazine Illustrations.—A case of some importance to photographers who supply illustrated articles to the magazines recently came before Mr. Justice Darling. Although the case concerned artists' drawings, it is to be presumed that the decision of the Court would apply equally to photographs. Drawings supplied for magazine articles remain the property of the artist (reports the "Daily Chronicle"). This was the conclusion arrived at after hearing a number of expert witnesses by a jury in Mr. Justice Darling's Court yesterday. The plaintiff was Mr. Ormrod Maxwell Ayrton, architect; and he sued Messrs. C. Arthur Pearson, Ltd., for £173 5s., the value of eleven drawings. Mr. Ayrton supplied materials for an article on weather vanes, and fifteen drawings for the purpose of illustrating it, receiving £10 for his services. When he applied for the return of his drawings he received a letter saying that eleven of them had been mislaid or lost in a spring cleaning. The defendants also said they were not liable, the custom of the profession being that all drawings became their property. Mr. A. Lys Baldry, art critic of thirty years' standing, stated that he had never heard of a custom that the drawings of artists became the property of the proprietors of magazines in which they were published. Where there was no special arrangement for the return of the drawings it was an understood thing that they were returned. In cross-examination, Mr. Baldry admitted that in the case of illus-

trated journals the drawings were generally bought outright. There was a great difference between illustrated journals and magazines. Mr. Clement Shorter, editor of the "Sphere," was called for the defence. He said he had had fifteen years' experience of illustrated journalism, and had been editor of the "Illustrated London News" and the "English Illustrated Magazines." There was a custom as between contributors to and proprietors of illustrated magazines and journals that drawings sent to illustrate articles became the property of the proprietors. Mr. Shearman, K.C. (for the defendants): In your experience is there any distinction between monthly magazines and weekly or daily papers?—None whatever. What do you say as to the amount claimed for the drawings?—I think it is quite absurd. Mr. Geo. F. Hammond, art editor of the "Illustrated London News," stated that his journal received a large number of drawings, and in the absence of any special contract they became the property of the proprietors of the journal. He had seen the four drawings which had been returned to Mr. Ayrton, and in his opinion it was preposterous to say they were worth £15 15s. each. Mr. Shearman: What do you say is a fair price for drawings of this class?—I can get as many as I require for a couple of guineas each. Mr. Stanley Wood, artist, stated that he had had sixteen years' experience as a black and white artist, and knew the custom was that the original drawings always belong to the proprietor of the magazine. Several other witnesses having stated that the custom in regard to magazines was that the drawings became the property of the proprietors, the jury found a verdict for Mr. Ayrton, and assessed the damages at £40. Judgment accordingly with costs.

DEATH of the Rev. J. M. Bacon.—We much regret to record the death of the Rev. J. M. Bacon, which took place on Christmas night at his residence, Cold Ash, Newbury, Wilts. The deceased gentleman was well known to photographers, through his lectures and writings on photography, as applied to scientific aeronautics, although his use of the camera was more in the direction of the popular presentation of his subject than in its more serious aspects. Describing Mr. Bacon as the "leading scientific aeronaut in England," the "Chronicle" says: "He was born in 1846, and was the son of Mr. John Bacon, and grandson of the Royal Academician of the same name. His early years were spent in the North of England. After the usual course of school and university education he decided to take Holy Orders, and was ordained in 1870, at the age of twenty-four. An active life followed his entry into the ministry, and he inaugurated and presided over many local institutions, but he first came to the front as a scientist in 1896, when he took part in the expedition sent by the British Astronomical Association to Vadsø, Lapland, to take observations of that year's eclipse of the sun. So well did he acquire himself of his charge that when another expedition was organised to study the solar eclipse of 1898, he was placed in full control, and successfully directed the operations of a party of astronomers at Buxar, India. In 1900 he took out a third party of scientists for a similar purpose to Wadesboro, North Carolina. Of late years Mr. Bacon was best known for his very numerous balloon ascents, and the equally numerous articles he wrote in connection with them. He was one of the most enthusiastic aeronauts in the country, and his fearlessness in pursuit of his favourite hobby seems to have communicated itself to his daughter, Miss Gertrude Bacon, who accompanied him on many aerial adventures. Nearly all his experiments had for their object the elucidation of some scientific problem—generally connected with either acoustics or meteorology. He made several essays in military ballooning. One of the most recent was connected with the possibility of delivering dispatches by balloon to a beleaguered city. During the summer of 1903 he carried out a trial on these lines, leaving the Crystal Palace grounds and dropping the dummy, "General Jacqueminot," on Blackheath—being attended through his course by a party of military cyclists. His latest and perhaps most valuable experiments, from a practical point of view, were conducted this year at his residence near Newbury, and had for their object the construction of a safe and effective hot-air balloon. The main features in his invention—in which he had the co-operation and assistance of Mr. J. N. Maskelyne—were a petroleum vaporiser and an asbestos safety tube or neck. It was anticipated that inflation by the new process would have the advantages of economy and efficiency, as compared with that by hydrogen or coal gas, and it is much to be regretted that his death has come to cut short these most interesting trials. Besides writing a great number of articles and scientific papers, Mr. Bacon narrated his aerial experiences in his books, 'By Land and Sky' and 'The Dominion of the Air,' and delivered many lectures on his favourite pursuit. During the course of many scores of balloon trips by land and sea he had some exciting experiences."

Correspondence.

THE EMPLOYEES UNION.

To the Editors.

Gentlemen,—I am glad to see there is a movement on foot to start an association of photographic employees. Several times I have been on the point of writing to suggest the desirability of such a movement, feeling that with the growth of photographic "industries" or "works" distinct from portrait businesses the number of persons engaged in photographic work who must necessarily expect to remain employees without the prospect of going into business on their own account is now so great that they can no longer afford to neglect the advantages to be gained by organisation. From the first suggestion by the P.P.A. of a means of classifying assistants by certificates and examinations, it has appeared to me that this would pave the way considerably to some method of fixing a standard minimum wage for a given efficiency on the part of an assistant. While there are no means of officially grading the workers according to their capabilities, it would be difficult, with so much inequality in the work turned out by professional portrait photographers, and the consequently varied attainments required, to do anything at all in the way of fixing wages. Now prospects seem better. What I am wondering is whether, considering the way in which photographic employees are scattered and the difficulty of getting any number of them together in any given time, it will be possible to get them to unite in sufficient numbers to make the scheme a success. The Shop Assistants' Union seemed likely to be one that should take the receptionists, though I was doubtful if it would be open to retouchers. The remarks of "Assistant" on page 1,078, line 32 from top left-hand column, although not mentioning any union by name, rather indicates that this would not be practicable. If, however, employees show no more enthusiasm for organisation than their employers have done, I am afraid it will be some time before anything in the way of sick benefits will be obtainable. All assistants, at any rate, should write to Mr. Palmer, and employers in sympathy with the movement might very well bring the matter under the notice of their staff.

I am afraid the average employee, like a good many P.P.'s, only reads his "Journal" when a change of crib or an answer in the "query column" is wanted.—Yours faithfully
 EMPLOYER.
 December 26, 1904.

AMMONIA IN EMULSIONS.

To the Editors.

Gentlemen,—To hear at the present day that a patent has been granted for an emulsion prepared with ammonia is ancient history, and, as the late Traill Taylor would say, "is cauld kale het agin."
 I believe I was the first to publish the ammonia formula, yet I believe that the credit is given to Dr. Monkhoven. I am very jealous of anyone getting credit where it is not due. Not only did I publish the double decomposition method, but the certain way of regulating the speed by the addition of ammonia carb. I read a paper before the Convention at the first meeting in Derby "on a method of increasing speed and density by stewing finished emulsion, with the addition of bromide and nitrates to prevent fogging." I believe you published the paper. I have also exhibited negatives taken on emulsion that had been subjected to acid treatment—sulphuric. The negatives were marvellously clear and dense. The development took only a few seconds, but the emulsion was slowed very much. Some time ago I came across a formula in a text-book. Had my name not been given I would not have recognised it. The compiler had evidently mixed several formulas together with some of his own. This to me is worse than plagiarism. I may say that, as far as I know, I have produced plates far, in a way, more sensitive than any produced at the present time by my published methods. Very few experimenters succeeded, for the simple reason that they were like "the cow that gave a good pail of milk and kicked it over"—i.e., spoiled it afterwards. We have a great deal to learn yet about emulsions. I regret that my arrangements and health do not permit me to continue these investigations.

Should any of your readers require any further information on this subject, I will not be able to reply before May 20, 1905, as I am en route to Sydney, Australia.—I remain, Sir, yours truly,

A. L. HENDERSON.

THE FIRST AMERICAN PHOTOGRAPHIC SALON.

To the Editors.

Gentlemen,—The note under the above heading on page 1,082 of your last issue makes for very serious thought, and if the exhibition is at all up to the standard outlined by your American contemporary it must be somewhat unpleasant, if not galling, to those who so strenuously opposed it and hysterically raved about the promoters being unfit to associate with and the two-pair back room of a second-class picture dealer.

Can you tell me whether there are any reproductions of pictures in this exhibition in any of your American contemporaries, and whether it is possible to see the same anywhere in London?—Yours faithfully,
 WILL EVANS.

London, E.C., December 24.

[Our American contemporaries are nearly all of them filled with reproductions of the said pictures, and we believe that every American photographic journal published may be seen in the library of the Royal Photographic Society, 66, Russell Square, W.C. Possibly some may also be seen at the Patent Office Library, Chancery Lane, W.C.—Eds.]

METRIC WEIGHTS AND MEASURES.

To the Editors.

Gentlemen,—In your issue of to-day I see a statement that by the Weights and Measures Act of 1897 the cubic centimetre ceased to be a legal measure of capacity, and you state that the processes of volumetric analysis the results would be vitiated by the employment of one unit instead of the other.

Inasmuch as the Order in Council made under the Act you name includes the cubic centimetre among the units whose standards are to be kept, I think that your meaning must be different from what I read it; but as to the difference in capacity being of any practical importance, I would point out that it required a long and expensive series of experiments to determine the difference (such as would be quite out of the question in the course of any analysis), and that, after all, the approximate amount of the difference between the litre and the cubic decimetre is about 2½ minims, a quantity which a small difference from the strict conditions of comparison would annul. Whether it is desirable to use the term "millilitre" or "cubic centimetre" for the small measure or to devise a new term is another question entirely; practically, I believe that the term millilitre is obsolete in the countries using the metric system. The litre is considered as consisting of 1,000 cubic centimetres, and when we are seeking to conform to general practice it seems undesirable to introduce new variations. There is, too, a strong objection to the use of "mil" for the name, because that has already been long proposed as the name for 1/1,000 of a pound sterling in a system of decimal coinage which is the logical accompaniment to decimal weights and measures.

As to the difficulty of procuring metric weights, etc., your correspondents need not wait to send to France. Messrs. Griffin, in Sardinia Street, or Messrs. George in Hatton Wall, have them always in hand, and there are many others who supply them. Prices will, of course, vary according to the nature of the purchaser's wants.—I am, Gentlemen, your obedient servant,
 J. F. T.

SURFACING OF BROMIDE AND CARBON PRINTS BY STEAM.

To the Editors.

Dear Sirs,—A slight inaccuracy has crept into your report of my demonstration before the Croydon Camera Club in your issue of the 23rd inst.

It is stated that the process is not applicable to carbon prints that have been treated with the usual alum bath. This is not the case, as I have used none but prints so treated. If the process were only applicable to non-alumed carbon prints its usefulness would be practically nil.

I have found, however, that the steaming has practically no effect on bromide prints toned by the hypo-alum boiling method.—Yours truly,
 J. M. SELLORS.

19, Dornton Road, Croydon.
 December 27, 1904.

Answers to Correspondents.

- *** *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- *** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- *** *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*
- *** *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

D. G. Bain, 1, Abbeymount, Edinburgh. *Photograph of the Rev. A. Bisset.*
 F. Coghlan, 31, Carlisle Road, Londonderry. *Two Photographs of St. Eugene's Cathedral, Londonderry, one showing the Bishop's House.*
 P. Ingham, Winton House, Ashton-upon-Mersey, Cheshire. *Photograph of Two Horses in Buggy with Miss E. S. Ross and Brother.*

CECILY.—You are likely to obtain what you want from Underwood and Underwood, of 3, Heddon Street, Regent Street, W., or W. Winter, Königstrasse 12, Leipzig-Connewitz.

AN 18 YEAR'S PRINTER.—The firm are perfectly with in their right in dismissing your son, though it is a mean shabby thing to do. You are quite helpless, and must just put up with the position of affairs.

COPYRIGHT.—"J. P. S." writes: "I have taken at different times the Mayors of this town for the last twenty-five years. In no case has ever any charge been made for doing so. If I made them copyright now would that prevent any one copying any prints that may have been disposed of, either to the public or to the parties themselves." In reply: Yes, certainly, and such a unique series is well worth copyrighting.

RETOUCHING.—"Would you kindly pass your opinion on enclosed retouched prints." In reply: When sending prints for criticism you should tone and fix them, otherwise they flatter the retouching. Commercially your work is very fair, but artistically it is weak, for you treat old faces with the same touch and method as applied to the youthful; and so remove character. Work softly and broadly and with less effort on the aged, and fully preserve the truthfulness of the likeness.

DIRECTORY OF PROFESSIONALS.—"CYRIL" asks: "Can you kindly tell me through your columns if there is any directory published of the professional photographers of England or Great Britain?" In reply: Some years back such a directory was published by Lund, Humphries and Co., but we should imagine that this was now much out of date. Kelly's Directory of Chemists and Druggists is, we imagine, the only available list, and we doubt the completeness of that.

ENGAGEMENT.—"IVY" asks: "Two months ago I was engaged for a permanency as retoucher and receptionist at £1 per week. I made the agreement that it was for a permanency or I should not take it a fortnight ago. I was told that I could have the next day and half the next, which I did not ask for or want, and the end of week had a day and a half's pay knocked off. The same this week because they were slack. Can I claim full money, as I am there waiting, and he says he cannot keep me after Christmas, as business is bad? I came from Ireland, and paid my own expenses, and it will be a big loss to me." In reply: If you were engaged by the week with a week's notice to be given on either side, you can claim full wages for the time during which you have been with your firm. Better consult a solicitor.

PLASTOGRAPHS.—W. LIVINGSTONE writes:—"We have had for sale (in New Zealand) here a number of series of views called 'Original Plastographs, by Max Skladanowsky,' which are published in Berlin. I need not describe them beyond saying that they are large views, printed in two colours, which, when viewed through stained gelatine, give stereoscopic effects. Doubtless the same things have come under the editorial eye. I should like you to explain what they are, and how made.

They are, of course, process prints. I have my own idea of the thing, but I find other people have their explanation of the matter. I have not, strange to say, seen any notice of them in your columns; if there has been one I have missed it, although I am a constant reader of the JOURNAL." In reply: This is, of course, using the idea suggested by Duodu Hanson, and patented by him in 1879, under the name of anaglyph. The method of producing these commercially is to take two stereo negatives, and from these make the necessary half tone blocks, and then print from the same, one in greenish blue, and the other in crimson, practically the complementary colours, not attempting to make them register, in fact there should be at least a displacement of three eighths of an inch between the images of an object in each pull. When the curiously irritating muddle is examined by a pair of lorgnettes, fitted with blue green and crimson glasses, or sheets of gelatine, the muddle resolves itself into a perfect stereoscopic picture.

BLUE PRINTING.—"I am writing you regarding some experiments I have been making lately in connection with engineering blue prints, in the hope that you may give me your opinion on the subject. The idea is to obtain prints direct from the ordinary blue print, which in the ordinary course of events would require to be traced, so as to provide a negative from which to print; a very tedious operation in most cases. The first difficulty was, naturally, to prevent the light penetrating the blue background before the lines become sharp. This I partly got over by changing the print to a brown colour—by bleaching in ammonia and then immersing in tannic acid. I found if the original print was on fairly thin paper I was able to get a positive copy of a kind with about 10 minutes exposure in a Hall's Electric Copying Lamp, but the chief difficulty (without very careful manipulation) was the tendency of the lines themselves to become yellow, which at once defeated the object of the process. To be able to print from the original blue print without treating it at all is the question. This could be done to a certain extent, and discontinued after the light began to penetrate the background, but the lines at this stage would require development. Is there any process whereby this could be done to suit the conditions of an ordinary printing-room, in say ferro-prussiate paper? If not, what paper would you suggest? It might be a wholly developing paper, but would not require to be expensive, as the average sizes of prints are 50 in. by 30 in. I enclose samples of prints at these different stages referred to, and shall be very pleased if you can give me any advice in the matter." In reply: There is no satisfactory method of treating a blue print to render the colour more active. All the processes fail in the matters you complain of, viz., yellowing of the ground and decrease of the general vigour of the print. We should advise you to print from the original drawing or tracing on to "sepia" or "brown-line" paper, which is practically just as simple in handling as blue paper, and can be worked with appliances, in the way of baths, etc., used for ferro-prussiate. From the negative copy—white lines on a blue ground—you can print positive copies on to the brown line paper, in which case you will get a print in brown lines on a white ground or on ferro-prussiate paper, in which case you get a blue line copy. The sepia paper is supplied by all the usual dealers in heliographic papers.

*** NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

A real bargain, £5 15s.—The City Sale and Exchange, 81, Aldersgate Street, E.C.

Continued on page XIX.

THE UNEMPLOYED.

Why should so many Photographers and other men join the ranks of the unemployed when, by investing in **FALLOWFIELD'S Button Apparatus or Automatic Ferrottype Cameras**, they could very quickly pay off the money borrowed and earn a fixed income all the year round?

The primary expense for a complete Photo Button Outfit, carriage paid to your door, would be £5, and you would then be in a position to make up buttons by the thousand for the local or any other photographer, or if you had the capital you could start a small business, but that would mean another £25, so I advise only the outlay of £5 to those who have not sufficient money to buy a photographer's practice.

You can be even more independent if you go in for Fallowfield's Automatic Ferrottype Cameras. For £8 I can supply the Camera, Plates, Stand, Mounts, Envelopes, Trays, Developers, and all necessary articles carriage paid. Of course this trade flourishes better in summer, but there is a demand all the year round, and the worker will be able to pay his hotel expenses and make a profit at any and every seaside resort round England, and a more enjoyable or healthy business could not be found.

Send for further particulars.

HARD SURFACE.**FREEDOM FROM FOG.**

LETO-GASLIGHT PAPER

IMPROVED . .
DEVELOPMENT

Yields bright platinum-like results. Leto-Gaslight Matt smooth possesses all the fine qualities of the Leto C.C. Platino Matt. It has a fine delicate surface and yields prints hardly distinguishable from Collodio-Chloride Matt Paper.

The Gelatine film does not soften in the solutions; in fact, in working it is similar to Collodio-Chloride.

Made in four Grades; Matt, Rough, Cream Crayon, and Glossy.

Sample Packets, 6d., post-free.

UNRIVALLED FOR ITS BEAUTIFUL DELICACY.

LETO Collodio-Chloride Paper PLATINO MATT.

YIELDS CARBON-LIKE EFFECTS.
PUREST WHITES.
UNSURPASSED IN QUALITY.
BEAUTIFUL COLOUR.
FOR DELICACY OF THE FINISHED PRINT.

Obtainable in sheets 24 x 20, gross boxes, and 1s. packets.

SAMPLE PACKET (Cabinet), post-free 6d.

SENSITISED POSTCARDS *and* BOARDDOIDS.

Made in two Grades: Matt white and Glossy mauve.

LETO (STOUT CARD).	The original LETO Collodio-Chloride Postcard. Unrivalled for beauty and brilliance of tone.	10d. per packet of 12.	7s. 6d. per Gross.
LETO-SPECIAL (THIN CARD).	Similar to above, only coated on a thinner, but most serviceable, card.	8d. " "	7s. 0d. " "
LETO-GASLIGHT.	Hard surface. Freedom from fog. Yield bright platinum-like results.	10d. " "	7s. 6d. " "
LETO-BROMIDE.	Purest whites. Rich velvety blacks.	10d. " "	7s. 6d. " "
SELTONA.	Self-toning. Need fixing only.	1s. " "	10s. 0d. " "

The above prices refer to full size ($3\frac{1}{2} \times 5\frac{1}{2}$). The Postcards are also made in COURT ($3\frac{1}{4} \times 4\frac{1}{4}$) and MICRO ($3\frac{1}{2} \times 2\frac{3}{4}$).

Obtainable of all Dealers, or direct from

THE LETO PHOTO MATERIALS CO., Ltd., RANGOON STREET,
LONDON, E.C.

Half Plate and 7×5 size Now Ready.

The Premo Film Pack.

"I am quite in love with the Film Pack. The most terribly alluring device I have ever touched."
"A. Horsley Hinton."

For 5s. the Film Pack Adapter can be made to fit your glass plate camera without impairing its use for glass plates

It will put you on an equal footing with the roll film camera man when you go afield.

The Pack contains twelve flat orthochromatic films all ready for use, and it may be put in the Adapter and taken out, when used, in broad daylight.

SOME OTHER ADVANTAGES:

The simplest, quickest, most efficient changing ever devised for flat films. The lightest, most compact, and portable attachment for glass-plate cameras.

Rapidity in making consecutive exposures.

Cut films one-fifth the weight of glass.

Each exposure focussed separately if desired.

Films and Plates used interchangeably.

Prices: Film Pack Adapters,

$\frac{1}{4}$ -Plate **4/6**, 5×4 **6/6**, $\frac{1}{2}$ -Plate or 7×5 **7/6**.

Send for the **BOOK OF THE FILM PACK**, illustrated, post free.

MAY BE OBTAINED FROM ALL DEALERS, or from

"STYLES"

(vide "B.J." Dec. 9th, 1904.)

"COSWAYS"—a style of portraiture which is new in many towns. Is it in yours? Why not be ahead of your competitor by being the first to introduce it? Send us your negatives for "Cosway" printing, we are specialists in Sepia-platinotype.

MOUNTING on ART PAPER without cockling. Better than any of the mountants mentioned by the writer of the above article, is our dry mounting system, whereby prints in any process may be mounted on the thinnest mounts without damage to either.

IF the proposition interests you—IF you are keen on "getting out of the rut"—send us 6d. and we will post you a specimen "Cosway" print, dry mounted on Japanese Vellum, together with our terms for doing your work.

— TWO SPEEDS —

NORMAL AND RAPID.

BOVRIL COMPETITION.

Facts that cannot be Ignored.

1st FACT.

319, Queen's Park Road, Brighton, Nov. 24th, 1904.

DEAR SIRS,

It is with great pleasure I inform you that the pictures which I entered in the recent Bovril Competition, were exposed on your Meteor Plates, which I purchased from dealers below.

Yours faithfully, A. H. AVERY,

WINNER OF HALF THE £10 BOVRIL PRIZE.
WINNER OF HALF A £5 BOVRIL PRIZE.
WINNER OF A £1 BOVRIL PRIZE.

2nd FACT.

106, High Street, Wealdstone, Nov. 28th, 1904.

GENTLEMEN,

I enclose you the two Winning Negatives I took for the Bovril Competition on your (Gem) Portrait Plates. I enclose original box and wrapper. I gave half-second exposures to each of these with f11 on a rather misty day, and I was very much surprised to find they were so fully exposed, as I quite made up my mind they were very much under

Yours faithfully, L. ALBON,

WINNER OF TWO £1 BOVRIL PRIZES.

3rd FACT.

A £1 Prize in this Competition was won by Mr. Hoppé, 12, Walpole Road, Strawberry Hill, Middlesex, the negative of his print being on a "Gem" Meteor Plate.

And Another Fact

Regarding speed and quality. Research and Industry have made The Gem "Salon" Plate touch the highest point yet attained by any plate, irrespective of price.

$\frac{1}{4}$ -plates, 1s.; $\frac{1}{2}$ -plates, 2s. 3d.; whole plates, 4s. 3d.

BRIN'S OXYGEN.

For Limelight, Medical, Metallurgical, and other purposes.

OXYGEN of guaranteed purity supplied in Cylinders of the best British manufacture, and complying with all the established Trade and Railway Regulations.

THE Public are respectfully informed that all Cylinders which are filled by the undermentioned Companies (whether their own or their Customers') are labelled with their Trade Mark. This label guarantees the purity of the Gas, and is a further guarantee that the Cylinder has been tested and proved sound in every respect by the Company which has filled it. Customers are requested to see that the Cylinders supplied to them bear this label, which is also stamped with the date on which the Cylinder was filled.

The Works of the Companies are open during business hours to Customers, who are at liberty to inspect the process of manufacturing Oxygen, and to witness their own Cylinders being tested and filled.

Price Lists of Gases, Cylinders, and all Accessories can be obtained from the Company's accredited Agents, or will be sent post free on application.

"18 Oct., 1903.

"It is a splendid Lens, and gives definition
"with the single lenses such as I did not
"expect. Of course, the double combination
"is very perfect."

MATTHEWS, PRICE & CO., Central Mills, Gough Street, Gray's Inn Road, London.
